**Abstract:** Background: Although migrant and seasonal farmworkers are highly vulnerable to ambient heat because of their working conditions, heat effects in this population have been rarely studied. Objectives: We estimated effects of heat on mean daily counts of clinic visits among migrant and seasonal farmworkers by taking advantage of a unique longitudinal medical records database in the USA. Methods: We compiled a daily weather and clinic visit data set based on data from five health centers located in five states (California, Colorado, Michigan, New York and Washington) for the summer of 2011-2014. A total of 303, 121 patients were included in our analysis, including 87, 687 migrant farmworkers and 215,965 seasonal farmworkers. We used Poisson regression to estimate the associations between heat and daily all-cause clinic visits among migrant or seasonal farmworkers or other clinic patients. We defined heat effects as the percentage difference in average daily counts of clinic visits, comparing 90-50th percentiles of daily mean apparent temperature, a composite index accounting for both temperature and humidity. We conducted a sensitivity analysis to evaluate the impact of adjustment for ozone levels and different heat definitions. Results: Although we did not observe statistically significant associations between heat and clinic visits among migrant and seasonal farmworkers across five centers, point estimates of heat effects are positive up to 6.5% for migrant farmworkers in two centers (Colorado and Michigan) and positive up to 16.3% for seasonal farmworkers in three centers (Colorado, Michigan and Washington). Conclusions: Our study appears to be the first to link heat effects with clinic data among migrant and seasonal farmworkers. This research suggests possible meaningful impact of heat on migrant farmworkers and provides justifications for further studies.

### **P03.0230. National Weather Service Heat Alerts and Emergency Hospital Admissions among the Elderly in 97 U.S. Counties**

Kate Weinberger

*Kate R. Weinberger<sup>1</sup>, Keith Spangler<sup>1</sup>, Antonella Zanobetti<sup>2</sup>, Joel D. Schwartz<sup>2</sup>, Kyle Foreman<sup>3</sup>, Yun Wang<sup>4</sup>, Francesca Dominici<sup>4</sup>, Gregory A. Wellenius<sup>1</sup>*

- 2. Environmental Health, Harvard T.H. Chan School of Public Health, Boston, MA, United States.*
- 3. Institute for Health Metrics and Evaluation, Seattle, WA, United States.*
- 4. Biostatistics, Harvard T.H. Chan School of Public Health, Boston, MA, United States.*

**Abstract:** Background: In an effort to reduce heat-related mortality and morbidity, the US National Weather Service issues heat alerts in advance of forecast extreme heat events to communicate risk to the public and government officials. However, in a previous analysis of 20 cities, we found no evidence of a protective association between heat alerts and mortality between 2001-2006, except in Philadelphia, Pennsylvania. The impact of heat alerts on measures of morbidity, especially in more recent years, remains unknown. Objective: To quantify the association between heat alerts and emergency hospital admissions among Medicare beneficiaries age  $\geq 65$  years living in 97 US counties, 2007-2012. Methods: We used overdispersed Poisson regression models to estimate the association between heat advisories and excessive heat warnings (collectively, heat alerts) and daily counts of emergency and urgent hospital admissions for any cause exclusive of external injuries. We adjusted for daily maximum heat index (lags 0-2), year, month, day of week, and federal holidays, as well as lagged heat alerts (lags 1-2). We pooled results across counties into a summary measure using standard meta-analytic methods. Results: Overall across the 97 counties, we did not find evidence of an association between heat alerts and hospital admissions (percent change in admission rate comparing days with versus without heat alerts: -0.1% [95% CI: -1.0, 0.7], p-value for heterogeneity: 0.94). We did not observe differences by sex, age group, or geographic region of the country. Conclusions: We did not find evidence that National Weather Service heat alerts are associated with lower rates of hospital admissions among the US elderly. The identification of factors that drive heat alert effectiveness is critical as the frequency and severity of extreme heat events is expected to increase over the 21st century due to climate change.

### **P03.0240. Temperature-Related Hospital Outpatients for Cardiovascular and Respiratory Diseases in Seven Major Cities of South Korea**

Honghyok Kim

*Honghyok Kim<sup>1</sup>, Garam Byun<sup>1</sup>, Hyomi Kim<sup>1</sup>, Yongsoo Choi<sup>1</sup>, Jong-Tae Lee<sup>2</sup>*

*2. School of Health Policy and Management, College of Health Science, Korea University, Seoul, Korea (the Republic of).*

**Abstract:** Background: There is limited evidence on ambient temperature effects on hospital outpatients for cardiovascular respiratory diseases. This study assessed the temperature effects in seven major cities (Seoul, Busan, Incheon, Daegu, Gwangju, Daejeon and Ulsan) of South Korea  
Methods: A time-stratified case-crossover design was used to assess relationship of daily mean temperature with hospital visits for hypertension (I10), ischemic heart disease (I20-25), heart failure (I50), cerebrovascular diseases (I60-69), pneumonia (J12-18), allergic rhinitis (J30), asthma (J45) and chronic lower respiratory diseases (J40-44) during the period of 2008-2015. City-specific distributed lag non-linear models were fitted using a conditional Poisson regression with over-dispersion. Lag intervals up to previous 14, 21 and 28 days of exposure were considered. Relative humidity, air pressure, holiday and influenza epidemic were adjusted for. Multivariate meta-analysis was conducted. Results: We found associations between low temperature and hospital visits for cardiovascular and respiratory diseases. For instance, compared to those at 50th percentile of temperature (14.8C), the pooled cumulative associations up to previous 21 days of exposure (cumulative relative risk) at 1st percentile of temperature (-6.6C) for hospital visits for hypertension and ischemic heart diseases were 1.23 (95% CI: 1.17, 1.30) and 1.14 (95% CI: 1.05, 1.24) respectively. Compared to those at 10th percentile of temperature (-0.6C), the pooled cumulative associations at 1st percentile of temperature (-6.6C) for hospital visits for allergic rhinitis and asthma were 1.15 (95% CI: 1.07, 1.25) and 1.09, (95% CI: 1.01, 1.18) respectively. Conclusion: This study suggests that exposure to ambient low temperature increases risk of hospital visits for cardiovascular and respiratory diseases.

### **P03.0250. Extreme Weather Conditions and Non-Cancer Mortality among Elders in Taiwan**

Ying-Hsuan Wu

*Ying Hsuan Wu<sup>1</sup>, Chi-Hsien Chen<sup>1</sup>*

*1. Department of Environmental and Occupational Medicine, National Taiwan University (NTU) College of medicine and NTU Hospital, Taipei City, Taiwan.*

**Abstract:** Background: Global climate change increases the frequency of extreme weather conditions, which may contribute to mortality risk, especially in vulnerable populations. Information on personal risk factors for extreme weather related mortality is still limited. Method: This studied included 115,856 adults over 65 years old participated geriatric health examination program between 2005 and 2012 in Taipei, Taiwan. Among this cohort, 12,958 elders died before 31 Dec 2012. The death month was retrieved from the National Death Registry. Extreme weather conditions were assessed at the residential townships. The among number of extreme weather days were calculated each month. For control period, case-crossover design was used to define the month before the death month. To evaluate the association between extreme weather conditions and mortality, Cox proportional hazard regression with the penalized smoothing spline was applied. The modification effects of several personal factors, including age, gender, lipid profile, renal function, uric acid, and thyroid function were also examined in this study. Results: Non-cancer mortality was associated with several characters of extreme temperature, including the monthly averaged IQR of daily temperature > 4Celsius(HR 1.10, 95%CI 1.03, 1.18), the monthly averaged day-time maximum temperature > 34Celsius (HR 1.11, 95%CI 1.02, 1.21), and the monthly number of extremely heat night days >12 days (HR 1.11, 95%CI 1.00, 1.23). If dividing the cohort by median age of death, significant effects of aforementioned weather conditions were only found among those >83 y/o. We didn't found potential modification effects of other biochemical markers. Conclusion: Higher variability of daily temperature and extremely heat night are associated with higher non-cancer mortality among elders, especially in older age group. Further studies are needed to identify underlining social and biological mechanisms.

### **P03.0260. Suicide and Ambient Temperature: A Multi-City Multi-Country Study**

Yoonhee Kim

Yoonhee Kim<sup>1</sup>, Ho Kim<sup>2</sup>, Antonio Gasparrini<sup>3</sup>, Ben Armstrong<sup>3</sup>, Yasushi Honda<sup>4</sup>, Yeonseung Chung<sup>5</sup>, Chris F. Ng<sup>6</sup>, Masahiro Hashizume<sup>6</sup>

1. *The University of Tokyo, Tokyo, Japan.*

4. *University of Tsukuba, Tsukuba, Japan.*
5. *Korea Advanced Institute of Science and Technology, Daejeon, Korea (the Republic of).*
6. *Nagasaki University, Nagasaki, Japan.*

**Abstract:** Previous literature suggests that higher temperature may play a role in increasing the risk of suicide, but little is known about the nonlinear temperature-suicide association. We examined a nonlinear exposure-response curve of the short-term association using a daily time-series data covering 294 locations in 10 countries (Brazil, Canada, Japan, South Korea, Philippines, Spain, Taiwan, UK, USA, and Vietnam) ranging from 4 to 40 years. We conducted a two-stage meta-analysis. In the first stage, we conducted a location-specific time-stratified case-crossover analysis to examine the short-term association between suicide and temperature (daily mean) using conditional Poisson regression. A distributed lag nonlinear structure for temperature was incorporated with the maximum lag of 6 days. In the second stage, we used a multivariate meta-regression to combine the location-specific lag-cumulative nonlinear associations by country and identify a range of temperature with the highest risk of suicide. In general, higher temperature was associated with the increased risk of suicide. However, suicide risk decreased rather than increased during extremely high temperatures (inverted J-shaped curve) in some locations, particularly for northeast Asian countries. The temperature with the highest risk of suicide for each country ranged from 91st to 99th percentile except the Philippines and the USA. The country mean cumulative relative risks at the temperature with the highest risk relative to that at the lowest were fairly consistent across countries, ranging from 1.27 (95% CI= 1.15-1.40) in the UK to 1.70 (95% CI= 1.35-2.15) in Taiwan, except for Vietnam at 2.69 (95% CI= 1.10-6.56). We found nonlinearity of the short-term temperature-suicide association. Our findings suggest that there may be a critical range of temperature that maximizes the risk of suicide, with the risk less high at extremely high temperature such as heat waves. On behalf of the MCC collaborative research network.

### P03. Built Environment, Noise and Greenness 3

#### **P03.0280. Urban Greenness Extracted from Pedestrian Video and Its Relationship with Surrounding Air Temperatures**

Sarah Henderson

*Kris Y. Hong<sup>1</sup>, Pak Keung Tsin<sup>2</sup>, Matilda van den Bosch<sup>2</sup>, Michael Brauer<sup>2</sup>, Sarah B. Henderson<sup>1</sup>*

*1. Environmental Health Services, BC Centre for Disease Control, Vancouver, BC, Canada.*

*2. School of Population and Public Health, The University of British Columbia, Vancouver, BC, Canada.*

**Abstract:** Background: Urban greenness has been associated with a wide range of health benefits, partially attributable to local cooling and visually-stimulated stress reduction. Several approaches have been used to assess greenness exposure at individual and population scales, but there is discrepancy between methods. Image processing of pedestrian video data, collected as part of a study on microscale urban air temperature, provide a novel source of street-level information on vegetation. Methods: Python was used to extract green, yellow, and shaded pixels from ~10 million frames of video footage collected during 40 sampling runs of 20 urban routes measuring 8-10 km. Resulting greenness values (combined total of green, yellow, and shaded pixels as a percentage of all pixels) were compared with concurrent air temperatures using correlations, time series plots, and maps. Shaded pixels were included because vegetation can generate large shaded areas on hot summer days. Results: The mean air temperature measured across the 40 runs ranged from 19.8 to 31.9 °C, with standard deviations ranging from 0.26 to 1.21 °C. In comparison, the mean greenness ranged from 52% to 65%, with standard deviations ranging from 6% to 13%. Correlations ranged from -0.61 to 0.34 and were in the expected direction for 31 of 40 runs, with plots and maps showing clear inverse relationships in many cases. Flat and weakly positive relationships occurred when background temperatures were low, conditions were overcast, or routes were closer to large waterways. Conclusions: Secondary data are limited for such evaluations, but with further refinement, our methods could provide unprecedented spatial and temporal resolution for greenness exposure assessment in individual-level studies. They could also be used to evaluate and compare models used to assess exposure at the population scale as long as the video footage is temporally matched with other methods, such as satellite overpasses or Google Street View imaging.

### **P03.0290. Built Environment Features Associated with Street Scape Attractiveness in 56 Cities across 28 Countries**

Andrew Larkin

**Abstract:** The built environment influences human health through several pathways, including environmental exposures and physical activity. Psychological pathway are also important but are not well understood given the difficulty in measuring related constructs (e.g. built environment attractiveness) and the specific components of built environments that contribute to these constructs (e.g. trees, density, mixed land use, etc.). We leveraged a novel crowdsourced data set (MIT Pulse Place) that included over 1.5 million pairwise comparisons of 424,929 Google street view images from 56 Cities across 28 Countries where individuals selected the image that was more beautiful. From these ranking we calculated a q-score for each image that ranged from 0 (lowest attractiveness) to 10 (highest attractiveness). We then derived multiple estimates of urban composition for each image to identify specific components of the built environment that are associated with streetscape attractiveness. We utilized a feature extraction deep learning algorithm to derive estimates of visible percent grass, trees, cars, sidewalks, roads, bushes, persons, houses, and sky from each image. Satellite-based estimates of road density, annual maximum NDVI, percent tree cover, population density, impervious surface area, and annual mean NO<sub>2</sub> and PM<sub>2.5</sub> were also derived from 100 and 250 meter radius buffers around the street view image locations. Preliminary results indicate that urban green space, especially tree canopy cover, is a particularly important driver of streetscape attractiveness. We are currently utilizing correlation globes, lasso variable selection, and regression modeling to further disentangle the relationships between built environment features, environmental exposures and attractiveness perceptions. A better understanding of these relationships will be used to inform future built environment health studies as well as policy and planning principals.

### **P03.0310. Green Spaces and Colon Cancer Risk: A Case-Control in Spain**

**Abstract:** Introduction: Green spaces have been associated with positive effects on various health outcomes. Few studies also suggest protective effect for cancer risk. Mechanisms explaining the beneficial effect of green spaces include increases in physical activity and reduced body mass index, both linked to colon cancer risk. Methods: We collected residential information for 1243 colon cancer cases and 3297 sex, age and area matched community controls between 2008-10 in 11 provinces (18 hospitals catchment areas) of Spain. We geocoded the longest residence of each participant and we assigned three indicators of exposure to green spaces within 300 m buffer: Access to urban green areas (>0.5 Ha) according Urban Atlas; access to agricultural areas according to CORINE Land Cover 2006; and surrounding greenness according to the average of the Normalized Difference Vegetation Index (NDVI). Detailed information on covariates was obtained. We used mixed models with hospital as random effect. All models were adjusted for age, education and socio-economical status (individual and area). We explored potential mediation effect by physical activity or body mass index (BMI). Results: Reduced risk of colon cancer was observed among those living close to urban green spaces [OR (95% CI)= 0.59 (0.47-0.75)]. Access to agricultural areas was associated with increased risk of colon cancer [OR=1.48 (1.22-1.8)] and with surrounding greenness [OR=1.19 (1.09-1.3)]. There was no suggestion for mediation by physical activity or BMI. Conclusion: The association between residential proximity to green spaces and risk of colon depends on the type of green space. Access to urban green spaces is associated with reduced risk of colon cancer, whereas access to agricultural is associated with increased risk. The mechanisms explaining this association are not clear.

### **P03.0320. Epigenetics, Built Environment and Atopy**

**Abstract:** Rationale Accurate estimation of gestational age (GA) using DNA methylation (DNAm) of umbilical cord blood, a novel development, provides relevant information on developmental stage. Studies of environmental exposures on GA are plentiful, but not using DNAm GA. We evaluated associations between DNAm GA, environmental correlates of the built environment and atopy. Methods Cord blood samples from 145 selected participants in the Canadian Healthy Infant Longitudinal Development study were examined, together with allergy skin prick tests at age 1 year. Exposure to greenness using satellite imagery, and individual exposure estimates to air pollution using land use regression models were assessed at home addresses throughout pregnancy. Associations of air pollution and greenness with DNAm GA residuals were tested while adjusting for maternal and neonatal characteristics. We further examined whether sensitization related to these environmental factors and DNAm GA. Results The mean GA was 276 (SD: 7.9) days, and mean DNAm GA was 279(5.8) days. There was a significantly positive correlation between these measures ( $r=0.66$ ;  $p<0.001$ ). Prenatal exposure to greenness showed borderline association with DNAm GA acceleration (i.e., older DNAm GA than chronological GA) (0.6 days, 95% CI: [-.6; 1.8] for one IQR exposure increase). Conversely, DNAm GA deceleration (i.e., younger DNAm GA) was associated with air pollution exposure during the first trimester (-2.1 days [-4.8; 0.7] for a 10  $\mu\text{g}/\text{m}^3$  exposure increase). 29% of this atopy-enriched sub-cohort were sensitized to at least one of 10 allergens. DNAm GA was a strong predictor of decreased risk of sensitization (OR: 0.93, 95%CI: [0.88; 0.99]), while air pollution exposure modestly increased the risk of sensitization by 4% ( $p=0.1$ ). Conclusion Our findings warrant in depth investigation of potential mediating role of DNA methylation on the association between allergic disorders and the built environment.

### **P03.0330. Health Impacts of Bike Sharing Systems in Europe**

David Rojas-Rueda

*David Rojas-Rueda<sup>1</sup>, Isabel Otero<sup>1</sup>, Mark Nieuwenhuijsen<sup>1</sup>*

*1. ISGlobal Barcelona, Barcelona, Spain.*

**Abstract:** Background: Bike-sharing systems (BSS) has been implemented in several cities around the world as policies to mitigate climate change, reduce traffic congestion, and promote physical activity. This study aims to assess the health impacts (risks and benefits) of major BSS in Europe. Methods: We performed a health impact assessment study to quantify the health risks and benefits of car trips substitution by bikes trips (regular-bikes and/or electric-bikes) from European BSS with more than 2000 bikes. Four scenarios were created to estimate the annual expected number of deaths (increasing or reduced) due to travelers exposure to physical activity, road traffic fatalities, and air pollution (PM2.5). A quantitative model was built using data from transport and health surveys and environmental and traffic safety records. The study population was travelers between 18 to 64 years old. Results: Twelve BSS were included in the analysis. In all scenarios and cities, the health benefits of physical activity outweighed the health risk of traffic fatalities and air pollution. In the current scenario of car trips substitution by BSS in these twelve cities was estimated an annual reduction of 5.17 (95%CI: 3.11-7.01) deaths, corresponding to an annual saving of 18 million of Euros. A hypothetical scenario was also build to estimate the potential of BSS if they substitute car trips. In this hypothetical scenario was estimated an annual reduction of 73 deaths (225 million Euros saving) in the twelve cities. Conclusions: The twelve major Bike-sharing systems in Europe provide health and health-economic benefits. The promotion of shifting car drivers to BSS can significantly increase those health benefits. BSS in Europe can be used as a tool for health promotion and prevention.

### **P03.0340. Traffic-Related Air Pollution, Noise and Infant Mortality in London**

Mireille Toledano

*Rachel B. Smith<sup>1</sup>, Daniela Fecht<sup>1</sup>, John Gulliver<sup>1</sup>, Sean D. Beevers<sup>2</sup>, David Dajnak<sup>2</sup>, Marta Blangiardo<sup>1</sup>, Anna Hansell<sup>3</sup>, Ross Anderson<sup>4</sup>, Frank Kelly<sup>2</sup>, Mireille B. Toledano<sup>1</sup>*

- 1. MRC-PHE Centre for Environment & Health, Imperial College London, London, United Kingdom.*
- 2. MRC-PHE Centre for Environment & Health, Kings College London, London, United Kingdom.*
- 3. UK Small Area Health Statistics Unit, MRC-PHE Centre for Environment and Health, Imperial College London, London, United Kingdom.*
- 4. Population Health Research Institute, St George's, University of London, London, United Kingdom.*

**Abstract:** Background There is evidence that ambient air pollution is associated with increased risk of infant mortality. Road traffic is a major contributor to ambient air pollution, but it also generates noise. This study investigates long-term exposure to both traffic-related air and noise pollution and risk of infant mortality. Methods We conducted a matched case-control study of infant deaths (deaths occurring in 1st year of life) from singleton births across Greater London from 2003-2010. Controls were singleton births in the study area between 2003-2010 surviving to age 1. Cases were matched to controls (n=29) on birthdate and sex. Monthly concentrations of NO<sub>2</sub>, NO<sub>x</sub>, source-specific traffic-related PM<sub>2.5</sub>, PM<sub>2.5</sub>, PM<sub>10</sub> and ozone were estimated at 20x20m resolution using a dispersion model, and time-weighted averages calculated for pregnancy/trimesters and birth to case death at address-level. Road traffic noise was modelled at address-level. We analysed the relationship between air pollutants/noise and infant mortality using conditional logistic regression, with adjustment for confounding. Results The study population comprises 3390 infant deaths (69% neonatal, 31% postneonatal). Average air pollutant exposures for cases from birth to death were 42µg/m<sup>3</sup> NO<sub>2</sub>, 77µg/m<sup>3</sup> NO<sub>x</sub>, 15g/m<sup>3</sup> PM<sub>2.5</sub>, 24g/m<sup>3</sup> PM<sub>10</sub> and 31g/m<sup>3</sup> O<sub>3</sub>. Average day- and night-time noise levels were 58 and 53 dB respectively. Higher road traffic air pollution and noise exposures were particularly associated with non-White ethnicity and lower socio-economic status. Preliminary results from adjusted single-pollutant models suggest increased risk of infant mortality associated with higher ozone exposure, but not with other air pollutants or noise. Analyses of joint air pollution-noise exposures are currently underway. Conclusions To our knowledge, this is the first epidemiological study to investigate risk of infant mortality in relation to both road traffic air pollution and noise co-exposures.

**P03.0350. Assessing the Contribution of Noise to the Association between Traffic-Related Air Pollution and Children's Respiratory Health**

Meredith Franklin

*Meredith Franklin<sup>1</sup>, Scott Fruin<sup>2</sup>, Rob McConnell<sup>2</sup>, Robert Urman<sup>2</sup>*

*1. Biostatistics, University of Southern California, Los Angeles, CA, United States.*

*2. University of Southern California, Los Angeles, CA, United States.*

**Abstract:** Traffic emissions are comprised of a complex mixture of components including tailpipe emissions, non-tailpipe emissions, and noise. While regulations have resulted in drastic reductions in tailpipe emissions, growing vehicle fleets and miles traveled have contributed to increased noise and non-tailpipe emissions such as brake wear, tire wear, and associated resuspended road dust. It is critical to assess effects of these lesser-studied non-tailpipe exposures particularly of noise, which can amplify the detrimental health effects associated with near-roadway exposure. Exposures to traffic noise, estimated from the Federal Highway Administration Traffic Noise Model (TNM), and NO<sub>x</sub>, estimated from a line-dispersion model, were spatially linked to the residential locations of children in the Southern California Children's Health Study. Lung function and asthma status were assessed for 1,397 children, and additional personal characteristics were recorded. Generalized additive mixed effects models were fit to assess the marginal and joint associations between NO<sub>x</sub>, noise and respiratory outcomes. In an adjusted model we found a 14.5 mL (95 % CI: -40.0, 11.0 mL) decrease in forced vital capacity (FVC) per interquartile range (13.6 ppb) increase in NO<sub>x</sub> that was strengthened to a statistically significant 34.6 mL decrease (95% CI: -66.3, -2.78 mL) after adjusting for a non-linear function of noise. The associations with FEV showed a similar result. Without taking noise into account we would have drastically underestimated the detrimental effects of exposure to traffic-related pollution, indicating the importance of jointly assessing multiple traffic-related pollutants. Further contributions of noise measured at intersections, as well as other important factors including particulate matter metals and neighborhood greenspace, enhanced our assessment of the full effects this multipollutant mixture on respiratory outcomes in a children.

**P03.0360. Association between Exposure to Noise and Sleep and Mental Health Outcomes in a Nationally-Representative Sample of U.S. Adolescents**

Joan Casey

*Joan A. Casey<sup>1</sup>, Aaron Shev<sup>2</sup>, Diana Paksarian<sup>3</sup>, Kathleen Merikangas<sup>3</sup>, Daniel Mennitt<sup>4</sup>, Kara Rudolph<sup>2</sup>*

*1. School of Public Health, UC Berkeley, Berkeley, CA, United States.*

*2. UC Davis, Davis, CA, United States.*

*3. National Institute of Mental Health, Bethesda, MD, United States.*

*4. Colorado State University, Fort Collins, CO, United States.*

**Abstract:** Background: In 1974, the U.S. Environmental Protection Agency (U.S. EPA) identified an equivalent 24-hour continuous average noise exposure level (LAeq, 24h) of < 55 A-weighted decibels to protect public health with an adequate margin of safety. To date, however, limited U.S.-based research has evaluated the relationship between noise pollution and health. We help fill this gap using data from a nationally-representative sample of U.S. adolescents. Methods: We used a cross-sectional geospatial sound model to estimate noise exposure at the block group level. We dichotomized noise as high (LAeq, 24h ≥ 55 dB) versus low (LAeq, 24h <55 dB). The National Comorbidity Survey Adolescent Supplement, conducted between 2001-2004 and including several self-reported sleep outcomes and DSM-IV disorder diagnoses, provided our study population. We evaluated the association between noise and sleep and mental health using doubly-robust targeted minimum loss-based estimation and propensity score matching to account for potential confounders, including air pollution. Results: The study included 4,508 urban-dwelling adolescents aged 13-18. Controlling for numerous adolescent, household, and environmental covariates, living in a high- versus low-noise census block-group was associated with later bedtimes on both weeknights and weekend nights (risk difference [RD]: 0.41 hours, 95% CI: -0.01, 0.83, and RD: 0.61 hours, 95% CI: 0.38, 0.84, respectively). We found no association with total number of hours slept. Further, we found that living in a high- versus low-noise census block-group was associated with 69% increased odds of an anxiety or depressive disorder (odds ratio [OR]: 1.69, 95% CI: 1.13, 2.25) and 79% increased odds of substance use disorder (OR: 1.79, 95% CI: 0.91, 2.66); we found no similar associations with behavioral disorders. Conclusion: We found evidence that noise exceeding the U.S. EPA threshold may hold adverse sleep and mental health consequences for U.S. adolescents.

### **P03.0370. Residential Green Space and Mental Health: Analyses of the Cartagene Population Cohort's Data**

Nolwenn Noise!

*Nolwenn Noise!<sup>1</sup>, Perry Hystad<sup>2</sup>, Yves Payette<sup>1</sup>, Catherine Boileau<sup>1</sup>*

*2. College of Public Health and Human Sciences, Oregon State University, Corvallis, OR, United States.*

**Abstract:** Built environment including green space may have an impact on health status like stress, cardiovascular diseases and mortality. However, little research has examined the effects on mental health, especially on a long-term frame. This study aims to explore the associations between depression, anxiety and exposure to green space using the CARTaGENE population cohort databases. The CARTaGENE Cohort databases were used in this study. Participants from urban area (Quebec, Canada) with residential history (>5years) were selected (n=8,144). Green space exposures were estimated using satellite derived measures (NDVI). Health outcomes included depression and anxiety determined through different manners: Administrative health databases, self-reported medical diagnosis, Patient Health Questionnaire (PHQ-9) and Generalized Anxiety Disorder (GAD-7) scales. Linear and logistic multivariate models were used to determine associations between green space exposures and mental health. Some evidence that urban green space is associated with decreased depression and anxiety were observed, although the magnitude of association varied by assessment method. A 0.1 increase in residential NDVI (100 m radius) was associated with an OR of 0.89 (95% CI: 0.81-0.98) for ever having a self-reported medical diagnoses of depression and 0.95 (95% CI: 0.88-1.03) for depression assessed through administrative health databases in the previous 10 years. For participants who have moved in a greener environment in the last 5 years, PHQ-9 and GAD-7 scores are lower (-0.37 and -0.30, respectively, p<0.05). This study demonstrates the potential of using population cohort databases to address environmental health issues. The CARTaGENE databases have the advantages to collect long-term health data (>10 years) and to allow the linkage with other databases. Trends arising from the analysis showed associations between green space and mental health that are highly dependent on the data sources.

**P03.0390. Assessment of the Impact of New Subway Stations on Public Transit Mode Share Using a Quasi-Experimental Design (Montreal, Canada)**

Sophie Goudreau

3. *Geography, McGill University, Montreal, QC, Canada.*
4. *Civil Engineering, University of Toronto, Toronto, ON, Canada.*
5. *Environmental and Occupational Health, School of Public Health, University of Montreal, Montreal, QC, Canada.*

**Abstract:** The use of public transit has been associated with increased physical activity through increased walking compared to car use, and thus to increased health benefits. Yet how increased public transit access has modified the use of public transit has received very limited attention. We aimed to assess the impact of three new subway stations in 2007, on the use of public transit in the greater Montreal region (Canada), with a quasi-experimental design. We used information from Origin-Destination (OD) surveys of 2003, 2008 and 2013 to assess public transit mode shares in 96 OD survey areas. We compared mode shares in the OD area where the subway stations was added (intervention area), to those of comparable control areas with no new subway stations. Those control areas were identified with a cluster analysis based on the 2003 characteristics of the areas related to transport behaviors (i.e. mode shares), built environment characteristics (e.g. population density, proximity to subway stations) and the socio-economic status of the residents (estimated with information from the 2001 Census). Mode shares were compared using difference-in-difference models, with matching of individuals from the OD surveys based on age, sex and income with propensity scores. Six out of 96 control areas were selected with the cluster analysis. The public transit mode share increased from 13% (2003) to 18% (2013) in the intervention area. This increases (+5%) is significantly greater than in control areas with no new subway stations (-1.9% to 1.9%). Thus, after 10 years, the differences in the evolution of public transit mode share between the intervention and each control areas ranged from +3.1% to +6.9%. The addition of new subway stations is associated with a non-negligible increase in public transit mode share, and future assessments should quantify its influence on physical activity and health.

**P03.0400. Exposure to Green Areas as a Way of Enhancing Health and Resilience in Cities: Metropolitan Area of Guadalajara, Mexico**

Maria Garibay-Chavez

*Maria G. Garibay-Chavez<sup>1</sup>, Arturo Curiel<sup>1</sup>, Marisol E. Cedillo<sup>1</sup>*

**Abstract:** Background/Aim: In rapidly-growing cities and urban settlements, green areas are identified as strategic zones to promote health, prevent disease and increase the resilience of individuals and communities. The aim of this study is to analyze the beneficial effects on health derived from the biodiversity in the green areas (urban parks) of the Metropolitan Area of Guadalajara (ZMG). Method: We identified urban parks > 100 hectares and a greater affluence of visitors in the ZMG. Five hundred surveys with open-ended and close-ended questions were answered by a sample of users above fifteen years of age. Data was collected on the reasons for their visits to the park, preferred sites within the park, activities undertaken and perceived benefits on their health. Through examination and observation, we recorded the ecosystemic services that exist in the park, the sites visited by users, their characteristics and appealing features. Findings: The green areas with more biodiversity and a greater opportunity to be exposed to microbiomes (freshness, presence of animals, scents) influenced activities such as walking, in a proportionally greater ratio (15%) than in parks where there is only recreational infrastructure. Likewise, tranquility (18%), relaxation (17%) and peace and quiet (15%) were also reported in a greater proportion, as benefits obtained in places with a greater biodiversity. In green areas, the preferred sites were gardens with diverse plant forms and textures, areas with animal presence or contact with animals and water (71%). Conclusions: When biodiversity and exposure to microbiomes are increased in green areas, more opportunities to benefit health are created and generates resilience among the people who visit them. Freshness in the environment, the presence of animals and scents were identified as beneficial exposure, derived from green areas which create a positive moods and reduce mental stress.

**P03.0410. Cardiovascular Diseases in Middle Aged and Older Adults in China: The Joint Effects and Mediation of Different Types of Physical Exercise and Neighborhood Greenness and Walkability**

Jun Wu

*Xianjie Jia<sup>2</sup>, Ying Yu<sup>2</sup>, Wanning Xia<sup>2</sup>, Shahir Masri<sup>1</sup>, Zhixiong Hu<sup>1</sup>, Mojgan Sami<sup>1</sup>, Zhaoxia Yu<sup>1</sup>, Jun Wu<sup>1</sup>*

*2. Bengbu Medical College, Bengbu, Anhui, China.*

**Abstract:** Both physical exercise and built environment have been associated with cardiovascular diseases (CVDs). Yet, few studies examined the influence of different types of physical exercise and multiple dimensions of built environment, their joint effects, and whether physical exercise mediates the effect of built environment on the risk of CVDs. We investigated different types of physical exercise and two important dimensions of built environment, namely greenness and walkability, on the risk of three common CVD outcomes (i.e. hypertension, coronary heart disease, and stroke) in a Chinese population aged 40 years or older. Data were collected for 1,944 residents from 32 communities across urban, suburban, and rural areas in Longzihu district of Bengbu, a typical second-tier city in China. Physical exercise was obtained from questionnaire surveys. Built environment factors included satellite-based Normalized Difference Vegetation Index (NDVI), Walk Score index, and questionnaire-based Neighborhood Environment Walkability Scale (NEWS). Multilevel logistic regression was used to estimate the associations of physical exercise and built environment with CVDs while accounting for within-community and within-subdistrict correlations and potential confounders. Significant associations were found for reduced risk of hypertension and coronary heart disease with walking/square dancing and Tai Chi, and reduced risk of stroke with walking/square dancing. Significant associations were also identified for reduced risk of hypertension, coronary heart disease and stroke with NDVI. Lower risk of hypertension and coronary heart disease was associated with higher Walk score; and lower risk of hypertension and stroke was associated with higher NEWS-based walkability score. We observed no interactions between physical exercise and the built environment, but physical exercise partially mediated the effects of greenness and walkability on the risk of CVDs.

### **P03.0420. Exposure to Artificial Light-At-Night and Obesity in a Population-Based Case-Control Study in Spain (MCC-Spain)**

6. Carlos III Institute of Health, Madrid, Spain.
7. Département de physique Cégep de Sherbrooke, Sherbrooke, QC, Canada.

**Abstract:** Background. Exposure to light-at-night and circadian disruption may increase cancer risk. In experimental animals light-at-night is strongly associated with obesity. We evaluated the association of exposure to artificial light-at-night (ALAN) with obesity in a population based multicase-control study. We applied a novel method for exposure assessment examining visual light and blue light spectrum. We evaluated chronotype, a characteristic that may relate to adaptation to light-at-night. Methods. We examined 1825 subjects (1129 population controls, 696 breast and prostate cancer incident cases; 919 men, 906 women) from Barcelona and Madrid, enrolled in 2008-2013. Indoor-ALAN information was obtained through questionnaires. Outdoor-ALAN was analyzed using images for 2012-2013 from the International Space Station (ISS) including data of remotely sensed upward light intensity and blue light spectrum information for each subject's geocoded longest residence. We examined excess-weight (BMI  $\geq 25$ ); abdominal-obesity (waist-hip ratio  $>0.85$  women,  $>0.90$  men) and overall obesity (WHR as above and BMI  $\geq 30$ ). ORs are adjusted for age, sex, education, center, case-control status and menopause (women). Results. Exposure to outdoor ALAN in blue light spectrum or visual light were not associated with measures of obesity (OR for highest tertile of blue light compared to lowest: 0.82 (95%CI 0.63,1.07) excess weight; OR=0.82 (0.60,1.13) abdominal obesity; OR=0.83 (0.61,1.13) overall obesity. ORs tended to be higher for subjects who slept in "quite illuminated" bedrooms compared to those sleeping in total darkness (excess weight OR=1.53 (0.98, 2.39); abdominal obesity OR=1.18 (0.68,2.03); total obesity OR= 1.36 (0.78,2.37). Results were similar when limited to controls and when mutually adjusting for indoor and outdoor light exposures. There was no effect modification by chronotype. Conclusion. Artificial light-at-night was not associated with excess weight or obesity.

### **P03.0430. Non-Occupational Noise-Induced Hearing Loss - an Emerging Epidemics: Current Status and Prevention Strategies**

Yulia Carroll

*Yulia I. Carroll<sup>1</sup>, John Eichwald<sup>1</sup>, Patrick Breysse<sup>1</sup>*

*1. NCEH, CDC, Atlanta, GA, United States.*

Abstract: Noise is the most common preventable cause of hearing loss, the third most common chronic physical condition in the U.S. Sources of noise in the community and the numbers of those attending loud events, have increased in recent decades. As this preventable hearing loss often progresses insidiously for years before being self-perceived or diagnosed, it underscores the need for improving the availability of public health information for individuals and their healthcare providers. In early 2016 the Centers for Disease Control and Prevention (CDC) formed a small unfunded intra-agency workgroup to address the issues of non-occupational noise-induced hearing loss. The vision of this workgroup is to provide data and education, increase awareness and prevent noise-related hearing loss at home and in the community. We analyzed audiometric and health survey data from the National Health and Nutrition Examination Surveys (NHANES) 2007-2010 and 2011-2012. We estimated prevalence of audiometric notches as indicators for hearing damage. We found that 17% of US adolescents (12 to 19 years old) and 24% of US adults have audiometric notches. The presence of noise-induced hearing loss increased from one in five among young adults aged 20-29 years to one in four among adults aged 50-59 years. The prevalence rate of audiometric notches for females increased from 16% in the 2005-2006 survey to 20% in 2007-2010, and are now higher than in males. Almost one in four adults who reported excellent to good hearing already have measurable hearing loss. About 20 million American adults have hearing damage indicative of noise exposure that may likely be due to everyday activities in their home and community. Prevention steps include avoidance and keeping noise down, as well as using personal hearing protection devices. CDC is also encouraging primary care providers and other clinicians, especially those involved in primary care, to ask about difficulty with hearing as part of routine care.

**P03.0450. Indoor Environmental Factors and Influenza-Like Illness in Community Dwelling Older Population of Hong Kong: A Prospective Cohort Study**

Lefei Han

*Lefei Han<sup>1</sup>, Nick P. Lau<sup>1</sup>, Lin Yang<sup>1</sup>*

*1. School of Nursing, The Hong Kong Polytechnic University, Hong Kong, Hong Kong.*

**Abstract:** Background: Previous studies have investigated the impacts of outdoor environmental factors (temperature, relative humidity (RH), absolute humidity (AH), rainfall) on seasonal variations of influenza virus activities. However, the findings were inconsistent to explain the circulation and summer surge of influenza in tropical and subtropical regions. We hypothesize that the controversial findings might be due to the lack of indoor environmental data. We conducted a prospective cohort study in community dwelling older people in Hong Kong to explore the relationship of indoor and outdoor environmental factors with incidence of influenza-like illness (ILI) in older people. Methods: A total of 231 older people aged 65+ years in the Hong Kong Island were recruited as index participants from Dec 2016 - Apr 2017. Automatic sensors were installed in the living room of each household to continuously collect the hourly indoor temperature and RH during the study period. The follow-up is still ongoing and expected to end by May 2019. Results: Here we report the preliminary findings of the first-year follow-up data from Dec 2016 - Mar 2018. Mean indoor temperature, RH and AH were 24.4°C, 68.1% and 22.2g/m<sup>3</sup> respectively. Indoor temperature and AH were highly correlated with outdoor temperature ( $r=0.95$ ) and AH ( $r=0.95$ ). While, indoor RH varied widely during June to September (difference  $10.8\% \pm 48.3$ ) and less correlated with outdoor RH ( $r=0.67$ ). The incidence rate of self-report influenza-like illness was 0.4 per person-year, and most were reported during May - Aug 2017 and Dec 2017 - Feb 2018. Preliminary results showed there was no significant difference between households with and without ILI cases, in terms of indoor environmental factors such as daily mean, minimum, median, maximum, variation of temperature, RH and AH. Discussion: Indoor-outdoor correlation was found high for temperature and AH but moderate for RH. Further analyses will be conducted when more data are collected.

### **P03.0460. Environmental Quality, Health and Learning in Conventional and High Performance School Buildings**

Stuart Batterman

*Stuart Batterman<sup>1</sup>, Cheryl Somers<sup>2</sup>, Geoffrey Thun<sup>1</sup>, Nan Yan<sup>1</sup>*

*1. UM, Ann Arbor, MI, United States.*

*2. Wayne State University, Detroit, MI, United States.*

**Abstract:** Aims: Schools are critical indoor environments that can affect the health, comfort and performance of children and teachers alike. We discuss lessons learned in an intervention study of schools and highlight issues related to ventilation, filtration and outcomes assessments. Methods: We compare indoor environmental quality (IEQ) parameters in a 37 recently constructed or renovated elementary school buildings, balanced between high performance and conventional buildings located in the US Midwest. We then compare results of interventions designed to increase ventilation and particle filtration (from MERV8 to MERV13) using a case-crossover design and repeated measures involving 550 students and 2 schools. We report on attendance, cardiopulmonary fitness using the Progressive Aerobic Cardiovascular Endurance Run (PACER) test, and student learning. We also characterize IEQ parameters in four classrooms in each school, using multiday measurements. The buildings varied in design, HVAC system, size, and other factors. Only 22% of classrooms met recommended minimum ventilation rates. Occupancy in many classrooms was highly variable, thus, the use of carbon dioxide (CO<sub>2</sub>) concentrations as a tracer for determining ventilation rates should use the transient mass balance method. It was sometimes difficult to detect significant differences in air change rates when ventilation rates were increased, and improving filtration did not always lower particulate matter concentrations. We show that increasing ventilation with low efficiency filters can increase PM<sub>2.5</sub> levels. Students and teachers had positive experiences with the PACER test. Conclusion: Intervention studies have strengths and allow investigation of both IEQ and student performance. Interventions must be carefully selected to ensure meaningful exposure contrasts and yield meaningful epidemiological evidence.

### P03. Exposure Measurement, Modeling and Other Methodological Issues 3

#### **P03.0470. Generating Consistent Spatio-Temporal Events of Exposure for Translational Exposomic Research**

Ramkiran Gouripeddi

*Ramkiran Gouripeddi<sup>1</sup>, Randy Madsen<sup>1</sup>, Lethuy Tran<sup>1</sup>, Peter Mo<sup>1</sup>, Nicole Burnett<sup>1</sup>, Ryan Butcher<sup>1</sup>, Mollie Cummins<sup>1</sup>, Katherine Sward<sup>1</sup>, Julio Facelli<sup>1</sup>*

**Abstract:** The concept of the exposome include endogenous processes within the body, biological responses of adaptation to environment, and socio-behavioral factors beyond assessment of exposures. Exposomes therefore need to cross-link locations and occurrences of environmental influences, and resulting direct biological pathway alterations as well as mutagenic and epigenetic changes on the phenome. Data representing these events need to be associated with their limitations and uncertainties associated with using the data as exact quantifications of exposure. In order to address these needs, we are developing a metadata-driven exposomic data integration platform, OpenFurther (OF), as a part of the Utah Pediatric Research using Integrated Sensor Monitoring Systems (PRISMS) Informatics Ecosystem (Grant NIH NIBIB U54EB021973). Based on the methods used for data collection (measurement or observation), and the differences and uncertainties in environmental measurements and true exposures, we grouped exposomic events into six broad categories: Sensor, Clinical, Biospecimen-derived, Participant reported, Aggregates, and Computational Models. Each of these events have spatio-temporal coordinates that can be unbounded, dense, discrete, instants & intervals, indeterminate, and at finest granularity available with the source. OF generates these event from heterogeneous study data and stores them as documents in Big Data stores. These high-resolution exposome records are used for spatio-temporal abstraction, reasoning and Big Data analytics methods. They can also be transformed with minimal transformational information loss into analytical models to support a diverse set of translational research archetypes including sensor development, environmental chemistry, exposure pathways, mechanistic understanding of environmental species on the genome for precision medicine, pharmacodynamics studies, clinical trials, observational, comparative effectiveness, and epidemiological studies.

### **P03.0480. Development of Analysis Method for Methanol in Detergent by GC-HS-MSD**

JeongSun Lee

*JeongSun Lee<sup>1</sup>, Younglim Kho<sup>1</sup>, Heeduek Yang<sup>2</sup>, Jung Hoan Kim<sup>2</sup>, Na-youn Park<sup>1</sup>, Hyojong Park<sup>1</sup>*

*1. Department of Health, Environment & Safety, Eulji University, Gyeonggi-do, Korea (the Republic of).*

*2. Food Technology & Service, Eulji University, Gyeonggi-do, Korea (the Republic of).*

**Abstract:** Methanol is the simplest alcohol compound and is a colorless, volatile, flammable, and liquid with a distinctive odor very similar to that of ethanol (drinking alcohol). Methanol is converted into a substance called formaldehyde in the body at the time of absorption and is fatal to the human body. Methanol may be exposed to the human body by oral, transdermal and inhalation. Analytical methods of methanol in detergent have been previously reported, but the analysis was difficult due to the complicated steps by Ministry of Food and Drug Safety. Therefore it is needed to develop a method for analyzing the methanol content in dishwashing detergents that are commonly used in the home. The range of calibration curves were 0.1, 0.5, 1, 2, 5, 10, 20, 50 and 100 ng/mL. Detergent is generally viscous and not volatile. The sample was injected in GC-HS-MSD after diluted 10 times in water. This study was validated for 3 days. Standard solution were added to the detergent at each 7 samples for level of 1, 10, and 50 ng/ml. Accuracy, precision, linearity, and LOD (limited of detection) were calculated for the inter-day, and intra-day. The accuracy of the intra-day result were 98.2%~104% (inter), and 98.0%~111.3% (intra). The precision were less than 20%. The detection limit was calculated to be 0.24 ng/mL. The linearity obtained was satisfying for the methanol, with a coefficient of determination ( $r^2$ ) higher than 0.999. This method has simpler pretreatment steps and lower detection limit than existing analysis method. It could be used as a basic data for monitoring methanol content analysis of detergent.

### **P03.0490. Environmental Data in Longitudinal Epidemiology**

Joshua Vande Hey

*Joshua Vande Hey<sup>1</sup>, Anna Hansell<sup>2</sup>, John Gulliver<sup>1</sup>, Andy Boyd<sup>3</sup>*

- 1. University of Leicester, Leicester, United Kingdom.*
- 2. Imperial College London, London, United Kingdom.*
- 3. University of Bristol, Bristol, United Kingdom.*

**Abstract:** The amount and diversity of data describing the natural environment are rapidly increasing. Accessing these data via record linkage provides excellent opportunities for environmental health research. However, there are varying research and data collection approaches across disciplines, as well as inconsistent awareness of established and emerging environmental data sources, their usefulness and their limitations. Based on experience of a multi-disciplinary team assessing impacts of air pollution in pregnancy and early life within the Avon Longitudinal Study of Parents and Children (ALSPAC) birth cohort located primarily in the city of Bristol in southwest England, we are developing practical guidance for identifying, assessing, selecting, combining, and linking environmental data to address questions in environmental epidemiology. **METHODS:** We mapped the data discovery, selection, and linkage process in air pollution exposure assessment for the ALSPAC cohort reported in Gulliver et al. (2018 Environ. Int.) and provided narrative on the process to highlight key steps and decisions that could inform translation to other cohorts. Multiple sources of data were searched, including national government and research datasets. We compared data extracted by Bristol City Council with local data discovered through an internet search. **RESULTS:** We found that while local sources of data vary considerably, there are key principles that can be applied to guide robust environmental epidemiology with an informed approach to dealing with uncertainty. We also found that evaluation of modelled exposures required local monitoring data only available from the city council. Critically, use of rich metadata and local knowledge meant some monitoring stations were found not to be representative and were not selected. **DISCUSSION:** We are developing an environmental data methodology that will inform epidemiological study design and analysis through dissemination to cohorts in the UK and internationally.

### **P03.0500. Exposure to Organophosphate Esters and Brominated Flame Retardants: What Does Your Cell Phone Tell You?**

Miriam Diamond

**Abstract:** Background Widespread exposure to organophosphate esters (OPEs), used as flame retardants and plasticizers, is of concern due to emerging data on toxicity. We aimed to identify OPE concentrations and pathways of exposure to Canadian pre-menopausal women, and to compare that with brominated flame retardants (BFRs). Methods From 51 women in Toronto and Ottawa, we measured concentrations of OPEs in air and floor dust in their homes, and on their hands and their electronic devices. 557 samples were analyzed for 23 OPEs, 9 "novel" brominated flame retardants and 14 PBDE congeners. Also, urine samples from 44 participants were analyzed for 8 OPE metabolites. Results and Discussion OPE air and dust concentrations were in the low ng/m<sup>3</sup> and µg/g ranges, respectively, for 5-8 OPEs with >80% detection frequency. BFRs were ~100X lower. Eight OPEs also had >80% detection frequency on hands (up to µg/cm<sup>2</sup> levels) that were similar in samples taken 3 weeks apart. Handheld electronic devices (e.g., cell phone, tablet) had significantly higher OPE (but not BFR) concentrations than non-handheld devices (e.g., TV, desk top). OPE concentrations on hands were most frequently correlated with those on cell phones, whereas BFRs on hands were correlated with laptops. Moreover, we found a significant correlation between total ΣOPE concentrations on cell phones and those in the corresponding urine sample, driven mostly by Triphenyl Phosphate (TPhP). We also found a significant correlation between the parent compound TDCPP in dust and cell phones and the corresponding urinary metabolite. Only TCPP on hands was correlated with its urinary metabolite. Conclusions Our study confirmed widespread exposure to OPEs among Canadian women. We found that OPE exposure could in part be explained by levels found on a woman's cell phone and secondarily by concentrations in her residential floor dust and her hands. It is not clear whether the cell phones are acting as a source or indicator of exposure to OPEs.

### **P03.0510. Evaluation of Exposure to Perfluorinated Chemicals (PFCs) due to Contamination of Drinking Water in Gloucester County, New Jersey**

Clifford Weisel

*Clifford P. Weisel<sup>1</sup>, Parsa Bahman<sup>2</sup>, Zhihua (Tina) Fan<sup>2</sup>, Chang Yu<sup>2</sup>, Panos Georgopoulos<sup>1</sup>*

*1. EOHSI, Rutgers University, Piscataway, NJ, United States.*

*2. Environmental and Chemical Laboratory Services, NJ DHHS, Ewing, NJ, United States.*

**Abstract:** Introduction: Perfluorinated chemicals (PFCs) are used in manufacturing stain resistant and water repellent consumer products and in firefighting foams at airports and military sites. They have been released into the environment inadvertently and when sprayed during firefighting scenarios and simulations. Due to their slow environmental degradation they have contaminated water supplies in multiple counties in the US potentially exposing more than 5 million people nationwide. The ground water in several communities in Gloucester County, NJ, particularly the municipal water in Paulsboro, was contaminated with perfluoro-n-nonanoic acid (PFNA) and perfluorooctanoic acid (PFOA). Since 2014, the water supplies have been filtered with activated charcoal. To assess the effectiveness of the water intervention program on reducing exposure to these PFCs, a convenience sample of 120 adult residents in the area have been recruited and twelve PFCs were measured in serum, household tap water, and household dust and a questionnaire administered as part of a CDC Biomonitoring grant. Results: The first visits have been completed and two more visits to each subject are planned approximately a year apart. Nine of the PFCs were routinely above the detection limits in the serum. The analyses of approximately half of the subjects have been completed, with the serum PFNA levels of the residents ( $5.9 \pm 9.5$ , median 3.3, maximum 60  $\mu\text{g/L}$ ) often exceeded the 95th% reported in the 2009-2010 NHANES levels for adults over 20 (3.94 (CI: 2.38-8.36)). The distribution of other PFCs serum levels were similar to that reported in NHANES. Water levels were below detection for all PFCs, indicative that the water intervention has effectively reduced the PFCs exposure through that route. PFCs were found in dust reflecting their use in consumer products. It is expected that the serum levels of PFNA will decline over the next few years if the drinking water was the main exposure source.

### **P03.0520. Recent Advancements in Method Development and Exposure Assessment for 45 Blood VOCs Analyzed by Headspace SPME GC-MS**

David Chambers

*David M. Chambers<sup>1</sup>, Christopher M. Reese<sup>1</sup>, Eduardo Sanchez<sup>1</sup>, Alai Fernandez<sup>1</sup>, Kasey C. Edwards<sup>1</sup>, Victor De Jesus<sup>1</sup>, Benjamin C. Blount<sup>1</sup>*

*1. Division of Laboratory Sciences, Centers for Disease Control, Atlanta, GA, United States.*

**Abstract:** For over three decades our laboratory has been developing and improving methods for quantifying toxic volatile organic compounds (VOCs) in blood in support of numerous national and regional studies, including nine National Health and Nutrition Examination Survey (NHANES) cycles. Absorption of VOCs most commonly occurs through inhalation, as 100% of blood circulates to the lungs for exchange with alveolar gas. The high blood:gas partition ratios of most VOCs favor preconcentration in the blood, but blood VOC equilibration with tissues and organs is what influences VOC elimination half-life. As such, VOC analysis in blood is best-suited for compounds that are stable in the body by offering a direct measure of VOC burden experienced by tissues and organs. The current analysis method uses headspace solid-phase microextraction (HS-SPME) and gas chromatography-mass spectrometry (GC-MS). Important to the success of this method is the use of isotopically labeled analogs specific to every compound to compensate for competition effects in the headspace and SPME fiber, as well as adsorption and volatilization losses. The combination of these techniques has enabled us to simultaneously quantify a broad array of VOCs (boiling points from 32 to 204 °C) in the low parts-per-trillion (ng/L) range from a 3-mL blood sample. This presentation will include an overview of the blood VOC method and describe recent improvements to achieve accuracy and precision of < 15% for nonpolar compounds (e.g., alkanes) and within 5% for most of the other VOCs. We will also describe noteworthy blood VOC trends in the United States and reveal new analytes that are to be included in future studies and NHANES cycles. In addition to individual VOC trends, we will describe recent work comparing relative VOC levels among participants using artificial neural networks as a means to objectively distinguish exposure between different VOC sources within a large population.

### **P03.0530. Use of Public Water Supply Fluoride Concentration as an Indicator of Population Exposure to Fluoride in England 1995-2015**

Tony Fletcher

*Giovanni S. Leonardi<sup>1</sup>, David J. Roberts<sup>1</sup>, Neville Verlander<sup>2</sup>, John Morris<sup>3</sup>, Diane Edwards<sup>4</sup>, Tony Fletcher<sup>1</sup>*

*1. Environmental Epidemiology, Centre for Radiation Chemical and Environmental Hazards, Public Health England, Didcot, United Kingdom.*

*2. Public Health England, London, United Kingdom.*

*3. University of Birmingham, Birmingham, United Kingdom.*

*4. Public Health England, Birmingham, United Kingdom.*

Abstract: Studies of exposure to fluoride may use Geographic Information Systems to estimate population exposure by geo-referencing water supply zone (WSZ) monitoring data for public water supplies (PWS) to small areas. Geo-referenced fluoride PWS monitoring data were available from 2005-2015, but only non-referenced data from 1995-2004. We aimed to determine whether the geo-referenced fluoride concentrations in 2005-2015 could be used as a proxy for 1995-2004 population exposure. We also aimed to estimate population exposure to fluoride/fluoridation in PWS in England. We allocated annual average PWS fluoride concentrations and fluoridation scheme flagging data from national monitoring data to small areas using GIS. We obtained population data from routine data sources. Mean fluoride concentrations were estimated for each year in each WSZ (a 'zone-year'), for the two periods 1995-2004 and 2005-2015, stratified by fluoridation scheme-flagging. We compared the WSZ-level period means using Spearman correlation. For the geo-referenced data, we estimated spatial and population distribution of the period-average fluoride concentration. Almost all (97%) of the 16,188 zone-years of PWS monitoring observations were linked to WSZ boundaries for 2005-15, but only 8249/21553 (38%) pre-2005 zone-years were linked to their post 2005 WSZs. Grand mean 1995-2004 (0.11mg/l (SD 0.12)) and 2005-2015 (0.11mg/l (SD 0.12)) fluoride concentrations were similar, and WSZ-level means were highly correlated in un-fluoridated zones (Spearman correlation 0.93), but differed (1995-2004 0.74mg/l (SD 0.22), 2005-15 0.78mg/l (SD 0.16)) and correlated weakly in fluoridated zones (correlation 0.31). Most (72%) of the population received PWS with <0.2mg/l fluoride, 18% 0.2-<0.7mg/l, and 10% with ≥0.7mg/l. We estimated population exposure to fluoride in PWS across England in the period 1995-2015. Fluoride concentrations appear stable over time in WSZs, more clearly in zones without a fluoridation scheme.

### **P03.0540. Mapping Drinking Water Systems for Population Exposure Assessment**

John Minnery

*2. Analytical Services, Public Health Ontario, Toronto, ON, Canada.*

Abstract: Drinking water is a recognized pathway through which populations can be exposed to biological and chemical hazards. We mapped Ontario Municipal Drinking Water Distribution systems (DWDS) by matching census areas to images of drinking water pipe networks. The new maps enable ongoing epidemiological research and surveillance by allowing linkage of both drinking water monitoring data and administrative health data sets to the residence of the population served. The location of drinking water distribution pipes for systems serving a population of 5,000, or more, were obtained from the Ontario Ministry of Environment and Climate Change (MOECC). Images of pipe networks varied widely in resolution and detail, and were scaled and aligned by a GIS analyst using Google Earth and ArcMap v10.3. The smallest geographic areas for which Canadian census includes population, age and sex data i.e. "dissemination areas" (DAs) were used to approximate the boundaries of water systems. The selected DAs were spatially joined to form 153 polygons which include area home to 10,930,166 people (85% of the Ontario population). Each DWDS polygon has a unique MOECC identification number to enable patient address and health-data linkage to extensive water quality and treatment data. Population data from DAs were pooled within a DWDS to enable water-system level calculations of disease incidence and prevalence rates, standardized for age and sex. As census boundaries do not match those of DWDS, the maps created unavoidably include some error. This error can be quantified as the proportion of the Ontario population currently receiving drinking water from private systems erroneously assigned to a DWDS due to proximity. Methods to quantify this error are discussed, including the registry of private domestic wells which reveals error increasing as system size decreases. Analysis reveals that the error proportion can generally be limited to less than 10% for population areas of less than 13,000 people.

### **P03.0550. Exposure to Strontium through Drinking Water Used in the Preparation of Foods**

Lisa Melnyk

*Lisa J. Melnyk<sup>1</sup>, Maura Donohue<sup>1</sup>, Maily Pham<sup>2</sup>, Joyce Donohue<sup>3</sup>*

*2. National Risk Management Research Laboratory, US Environmental Protection Agency, Cincinnati, OH, United States.*

*3. Office of Science and Technology, US Environmental Protection Agency, Washington DC, MD, United States.*

Abstract: Strontium (Sr) is a natural element, ubiquitous in the environment and known to occur in water, food, air, and soils. Strontium is present in media as a salt or an ionized divalent cation. The Sr ion (dissociated) is toxicokinetically important because it is easily absorbed into systemic circulation when inhaled as particulates or ingested with water or foods. Identifying all routes of exposure to Sr is important for determining the relative source contribution (RSC). The RSC analysis is conducted to compare the estimated exposure expected in the general population from drinking water to exposure from intake of other media, including food. Ideally, a RSC analysis considers both the intake of a chemical from direct ingestion from tap water, as well as, contribution to the diet during preparation of foods when cooking with tap water and other sources. Research to determine the amount of Sr transferred from contaminated drinking water to individual foods during preparation was conducted. Strontium transferred to broccoli, lentils, and spaghetti at all levels tested (1.5, 10, and 50 mg/L) as evidenced by the residual Sr in the pour-off water following food preparation (33 - 64%). The data from the cooking study support the hypothesis that cooking of foods with water containing Sr adds to the total dietary Sr. A more comprehensive understanding of the contribution of water to dietary intakes through food preparation practices supports a more robust analysis of the tap water contribution to total daily dietary exposure. The views expressed in this presentation are those of the authors and do not necessarily represent the views or policies of the U.S. Environmental Protection Agency.

### **P03.0560. Contaminants of Emerging Concern during De Facto Water Reuse**

Susan Glassmeyer

*Susan Glassmeyer<sup>1</sup>, Edward T. Furlong<sup>2</sup>, Dana W. Kolpin<sup>3</sup>, Marc A. Mills<sup>1</sup>*

- 3. Central Midwest Water Science Center, US Geological Survey, Iowa City, IA, United States.*

**Abstract:** The drinking water and wastewater cycles are integrally linked. Chemicals that are present in household wastewater may be sufficiently mobile and recalcitrant to pass through on-site or municipal wastewater treatment and survive natural environmental removal processes. Such persistent compounds have the potential to reach surface and ground waters that may be a source of drinking water. The US Environmental Protection Agency and US Geological Survey are collaborating to examine the sources, fates, and potential effects of contaminants of emerging concern (CECs) during de facto water reuse which occurs when treated wastewater is discharged to a source of drinking water. The project sampling design follows a surface flow path, with the collection of grab water samples from upstream of a wastewater treatment plant outfall and downstream to a drinking water treatment plant intake and through the plant to a finished water sample. The study uses an integrated approach that includes a comprehensive analysis of over 200 specific chemicals (e.g. pharmaceuticals, per- and polyfluoroalkyl substances); high resolution mass spectrometry to identify non-targeted (unknown) chemicals; in vitro bioassays (e.g. estrogenicity, androgenicity); rapid whole organism screens to assess cumulative bioactivity; and in vivo tests to address specific exposure and response endpoints. A rigorous quality assurance/quality control protocol was consistently applied from field to laboratory to ensure comparability of results from different techniques. This consistent, integrated approach combines the strength of each technique and builds upon the traditional CEC research approach by including environmental and toxicity endpoint assessments to more fully explore the potential effects to human health and the environment from chemical exposures. This presentation will provide an overview of the study and results from the analysis for organic and inorganic chemicals from the samples.

### **P03.0570. The Transformation of Microcystin-LR during Tap Water Treatment Process**

Xinliang Ding

*Weijie Zhou<sup>1</sup>, Meihua Dong<sup>2</sup>, Jiandong Jiao<sup>3</sup>, Xinliang Ding<sup>2</sup>*

- 1. Public Health Department, Wuxi Center for Disease Control and Prevention, Wuxi, Jiangsu Province, China.*
- 2. Wuxi Center for Disease Control and Prevention, Wuxi, China.*
- 3. Wuxi Center for Disease Control and Prevention, Wuxi, China.*

**Abstract:** Objective To establish a liquid chromatography-tandem mass spectrometry (LC/MS/MS) method for the determination of microcystin-LR (MC-LR) in drinking water, investigate its removal efficiency during tap water advanced treatment process and analyze its degradation products in the tap water. Methods Water samples were collected from each point of tap water advanced treatment process and treated by mixing, filtration, concentration, elution, nitrogen blow and re-dissolvement. The samples were analyzed by LC/MS/MS to determine the MC-LR concentration and its removal efficiency during treatment process. The combination of actual water enrichment and laboratory simulated water were used to qualitative analyze the MC-LR degradation products by Orbitrap mass spectrometry. Results The linearity of MC-LR ranged from 2 µg/L to 200 µg/L with the detection limit of 0.0079 µg/L and the limit of quantification of 0.0263 µg/L. The recovery rate of MC-LR from different concentration in drinking water were from 94.88% to 101.47%. The intra-day precision was 2.51%-7.93% and the inter-day precision was 3.24%-8.41%. The average concentration of MC-LR in source water was 0.631 µg/L, 94.0% of which can be removed by ozone exposure, biological pre-treatment and chlorination. The remaining can hardly be removed by sand filtration, ozone exposure, activated carbon, ultrafiltration and other processes. The MC-LR average concentration in the finished water maintained at about 0.036 µg/L. Four degradation products were identified in the laboratory simulated water of the mixture of MC-LR and liquid chlorine in the mass ratio of 1:10. Conclusion the established MC-LR detection method can be well applied to the monitoring of MC-LR in drinking water due to its simple pre-treatment process and good methodological validation parameters. The removal efficiency of treatment processes was different.

## **P03.0590. Bridging Observational Studies and Randomized Experiments by Embedding the Former in the Latter**

Marie-Abele Bind

*Marie-Abele Bind<sup>1</sup>, Donald Rubin<sup>1</sup>*

*1. Statistics, Harvard University, Faculty of Arts and Sciences, Boston, MA, United States.*

Abstract: Consider a statistical analysis that draws causal inferences from an observational dataset, inferences that are presented as being valid in the frequentist senses; i.e., the analysis produces: 1) consistent point estimates, 2) valid p-values, valid in the sense of rejecting true null hypotheses at the nominal level or less often, and/or 3) confidence intervals, which are presented as having at least their nominal coverage for their estimands. For the hypothetical validity of these statements, the analysis must embed the observational study in a hypothetical randomized experiment that created the observed data, or a subset of that hypothetical randomized data set. This multistage effort with thought-provoking tasks involves: 1) a purely conceptual stage that precisely formulate the causal question in terms of a hypothetical randomized experiment where the exposure is assigned to units; 2) a design stage that approximates a randomized experiment before any outcome data are observed, 3) a statistical analysis stage comparing the outcomes of interest in the exposed and non-exposed units of the hypothetical randomized experiment, and 4) a summary stage providing conclusions about statistical evidence for the sizes of possible causal effects. Stages 2 and 3 may rely on modern computing to implement the effort, whereas Stage 1 demands careful scientific argumentation to make the embedding plausible to scientific readers of the proffered statistical analysis. Otherwise, the resulting analysis is vulnerable to criticism for being simply a presentation of scientifically meaningless arithmetic calculations. The conceptually most demanding tasks are often the most scientifically interesting to the dedicated researcher and readers of the resulting statistical analyses. This perspective is rarely implemented with any rigor, for example, completely eschewing the first stage.

## **P03.0600. Neonicotinoids in Honey Bee Produced in Jalisco, Mexico: Analysis of Environmental and Human Exposure**

Gilda Ponce-Vejar

*Gilda R. Ponce-Vejar<sup>1</sup>, S. Lizette Ramos<sup>1</sup>*

*1. Environmental Health, University of Guadalajara, Zapopan, Jalisco, Mexico.*

**Abstract:** Neonicotinoids (NN) have been used worldwide, since 1990's as a novel insecticide. There is scientific evidence of environmental affectation, due to its systemic and persistent action. Use of NN indicates that plants translocate it into their pollen, nectar and fruits. Because these compounds cannot be washed away, NN has been detected in our food system and human body. In Mexico there are 7 NN government's approved for domestic use, for use in pets, forestry, corps and livestock. Jalisco is an important Mexican states in food production, to include bee honey production, which has seen a 15% decline in the last years. It is suspected that NN have played a role in this decline. A lack of scientific studies regarding the use of NN's on the environment and the particular effects on humans creates a critical need in Mexico for further assessment. In the pilot, and follow-up study, honey is used as an indicator of surrounding environmental quality determining residual levels of NN. **Method:** During the pilot and follow-up study, based on land uses, honey samples were collected from 30 different Jalisco locations during 1 harvesting season. Samples were analyzed via an LC-MS/MS multi-residue screen for NN concentration at ng/gr in the Agriculture and Food Laboratory from Guelph University. **Results:** Pilot study found pesticide (NN and organophosphates) residues in honey and wax. This indicates that the beehives, larvae and bees have been exposed to pesticides. 30 additional samples were analyzed in order to identify NN at ng/gr. Honey's residue level of NN results were compared with EU LMR Codex Alimentarius in order to describe environmental and human exposure based on in vivo/vitro recent studies. **Conclusion:** This study improves our understanding about the NN environmental and human exposure through honey. We identified that the different levels of NN concentrations are related with land uses and the food produced in each region (e.g., avocado, corn, berries,).

**P03.0610. National Estimation of Seafood Consumption in Mexico: Implications for Exposure to Methylmercury and Polyunsaturated Fatty Acids**

Alejandra Cantoral

*Alejandra Cantoral<sup>1</sup>, Carolina Batis<sup>1</sup>, Nil Basu<sup>2</sup>*

*1. Research Center for Health and Nutrition , National Institute of Public Health, Cuernavaca, Morelos, Mexico.*

*2. Canada Research Chair in Environmental Health Science, McGill University, Ste. Anne de Bellevue, QC, Canada.*

Abstract: Background: Seafood is a good source of Omega-3 polyunsaturated fatty acids (w3-PUFA) but also contains the toxic contaminant methylmercury (MeHg). National estimates of exposure to both compounds through seafood intake in Mexico are not known. The objective of the current study was to describe national seafood consumption habits and to estimate seafood-based exposure to w3-PUFAs and MeHg. Methods: We analyzed data from a 24-h dietary recall extracted from the 2012 National Health and Nutrition Survey of Mexico (n= 10,096 subjects aged 1y and older). National per capita seafood intake, as well as information on age, sex, socioeconomic status, and geographic region was obtained. The contribution of each seafood item to the total MeHg exposure was estimated, as was the balance between estimated exposures to w3-PUFAs and MeHg. Results: A mean daily seafood intake of 10 g/day was estimated. The top species consumed in decreasing order were: canned tuna, sunfish, shrimp, mullet, carp and schoolshark (constituted 60% of seafood intake). Canned tuna and schoolshark contributed 75% of the population's estimated exposure to MeHg. The best balance of population-level exposures to w3-PUFAs and MeHg was found in salmon, sardine, trout and anchovies. Conclusion: Environmental dietary exposure to MeHg is a public health concern and thus a good understanding of seafood consumption is needed to create national consumption guidelines. The current study provides nationally-representative data in Mexico from which decisions can be made and future studies conducted.

### **P03.0630. Determination of Perfluorinated Compounds Level of Domestic and Imported Crabs in South Korea**

HeeDeuk Yang

*HeeDeuk Yang<sup>1</sup>, Jung Hoan Kim<sup>1</sup>, Younglim Kho<sup>2</sup>, Seogyong Choi<sup>3</sup>, Kwang-Won Lee<sup>3</sup>*

*2. Department of Health, Environment & Safety, Eulji University, Gyonggi-do, Korea (the Republic of).*

*3. Department of Biotechnology, College of Life sciences and Biotechnology, Korea University, Seoul, Korea (the Republic of).*

Abstract: Perfluorinated compounds(PFCs) are an organic fluorine compound that hydrogens of all of carbons compound were replaced by fluorine. PFCs were demonstrated for toxic effects by various studies. PFCs tend to accumulate because of the long half-life in vivo. Research on PFCs level of food material in South Korea is still in insufficient. In this study, we analyzed 19 PFCs in crab meat with LC-MSMS. A total of 151 crabs were collected from fish market of South Korea. The samples taken included countries of origin information; South Korea (n=104), China (n=37) and India (n=10). Crab samples were homogenized with water. Each sample was weighed (1g) and spiked 20 µl internal standard. PFCs were extracted from samples using ion-pairing extraction after enzyme hydrolysis. Quantitative analysis was performed with liquid chromatography-tandem mass spectrometry(LC-MS/MS). As result, PFOA was detected in South Korean and Chinese crab samples. PFTrDA and PFDS levels were higher in Chinese crab than South Korean Crabs. Although the legal criteria of PFCs in food is not yet defined, the levels of PFCs in South Korean crabs were similar to or less than other studies performed in aboard; Belgium (PFOS ranged from 93 to 292 ppb), China (PFOS up to 82.2 ppb) and Japan (PFOA ranged from 5.6 to 14 ppb).

### **P03.0640. Determinations of Triclosan and Parabens in Household Dusts by Solid-Phase Microextraction with Microwave Assisted Extraction**

Shih-Wei Tsai

*Yu-Jou Lin<sup>2</sup>, Shih-Wei Tsai<sup>1</sup>*

*1. Institute of Environmental Health, National Taiwan University, Taipei, Taiwan.*

*2. Institute of Environmental Health, National Taiwan University, Taipei, Taiwan.*

Abstract: Indoor dust has been known as a sink for many semi-volatile organic compounds, such as triclosan and parabens. Since indoor environment can protect dust from sunlight, rain and biological degradation, pollutants then could be persistent and accumulated in the residential environment. Up to now, the analysis of triclosan and parabens in dust is solvent and time consuming. Therefore, a method for the measurement of triclosan and parabens in dusts simultaneously by using microwave assisted direct-immersion solid-phase microextraction (MAE-DI-SPME) has been developed to determine the distributions in Taiwan. In this study, commercial vacuum cleaner was used to collect household dusts while particles with diameter smaller than 150 $\mu$ m were filtered out by stainless mesh. Afterwards, 0.02g dust sample was spiked with 2.5  $\mu$ g/g of surrogate in a 4mL vial and stood for overnight. RO water of 2.5mL was added into the sample the next day, followed by the filtration and MAE-DI-SPME extraction procedures. Gas chromatograph-tandem mass spectrometer (GC/MS/MS) was employed for the analysis. Several parameters affecting the SPME extraction efficiency were optimized. The results showed that the desorption efficiency was 100% when the desorption time was 20 min under 250 degree C. The best suitable fiber coating was 65 $\mu$ m PDMS/DVB and the optimum condition of MAE-DI-SPME for extraction of triclosan and parabens in dust was 20 minutes at 80 degree C. For indoor dust samples in Taiwan, the median, mean and range of triclosan and parabens concentrations were determined, respectively. Relatively to headspace extraction, the established method of MAE-DI-SPME for the measurements of triclosan and parabens in indoor dust provides good linearity and precisions. Besides, compared with traditional extraction methods, the MAE-DI-SPME provides a time saving, easy for operation and solvent-free procedure.

## **P03.0650. Investigation of Factors Associated with Measurements of Personal Light (Including UV) Exposure Levels**

Yuji Nishiwaki

*Yuji Nishiwaki<sup>1</sup>, Keiko Asakura<sup>1</sup>, Haruhiko Imamura<sup>1</sup>, Norihito Eto<sup>2</sup>*

*1. Department of Environmental & Occupational Health, School of Medicine, Toho University, Tokyo, Japan.*

*2. Department of Biomedical Engineering, School of Engineering, Tokai University, Kanagawa, Japan.*

**Abstract:** Background/Aim Although concerns over the effects of light (including ultraviolet [UV] light) exposure on health are growing, accurate estimation of personal light exposure levels is difficult, because they are affected by many factors. We used a novel mobile sensing device to measure personal light exposure. Measurements taken under varying conditions were compared: 1. subjects' behaviour, 2. time, 3. weather, and 4. location of the device. In this session, we report our measurements of UV exposure. Methods Light exposure was measured for 5 volunteers in a series of 15-minute periods on a total of 24 days in the same park in Kanagawa Prefecture, Japan. Measurements were taken under different conditions for comparison. First, measurements taken when the subjects were under no behavioural restriction were compared with those taken when certain behaviours were dictated. Second, measurements were taken at different times of day: At solar noon, 2 hours before, and 2 hours after. Third, measurements taken under 4 different levels of cloud cover were compared. And fourth, comparisons were made according to which part of the body the devices were attached to: The face, shoulder, chest, wrist, or leg. Results Levels of personal UV irradiance were not affected by subjects' behaviour or by time of day. However, they were affected by device location, with the highest levels measured at the shoulder; levels decreased in the following order: chest, wrist, face, and leg. Levels also decreased according to the extent of cloud cover. Conclusions Our findings suggest that weather conditions and device location are significant factors in personal UV exposure level measurements. We are planning to use our findings to carry out an epidemiological study on the association between UV exposure and serum vitamin D concentrations in Japanese subjects.

### **P03.0660. Selecting the Best Method among Several: Bayesian and Classical Data Analyses Comparison in a Complex Microbiological Validation Setting**

Yvette Bonvalot

*Yvette Bonvalot<sup>1</sup>, Irene Iugovaz<sup>2</sup>, (MMC) Microbiological Methods Committee<sup>3</sup>*

- 1. Controlled Substances and Environmental Health, Regulatory Operations and Regions Branch (RORB), Health Canada, Longueuil, QC, Canada.*
- 2. Laboratories, Regulatory Operations and Regions Branch (RORB), Health Canada, Longueuil, QC, Canada.*
- 3. Bureau of Microbial Hazards, Food Directorate, Health Products and Food Branch (HPFB), Health Canada, Ottawa, ON, Canada.*

Abstract: Statistical procedures to compare new methods to gold standards, after validation of microbiological food methods, exist. However, evaluation of the best microbiological detection method among several is more challenging; there is little precedent in scientific literature. Our work compares Bayesian hierarchical (BH), Bayesian logistic Anova-like (BL-AL) and Classical logistic (CL) models using an original validation study, based on Health Canada's Microbiological Methods Committee guidelines. The validation study design includes 6 microbiological methods, 13 food panels of 20 samples each, and 10 laboratories, and theoretically generates 780 sub-groups, reduced to 198 after quality review. In classical statistics this would lead to 231 null hypothesis tests, requiring significance level ( $\alpha$ ) correction for multiple comparisons. Assuming non-informative priors, BH and BL-AL estimations include meaningful parameters (e.g. method detection rate (DR), DR differences between methods, etc.), reallocate their credibility based on observed data, and provide posterior distributions and 95% high credibility intervals (HCrI). Joining HCrI with pre-defined Regions of Practical Equivalence (ROPEs) allows for null hypotheses decision making: rejection, acceptance, or no decision. BH and BL-AL give similar results and posteriors. Posteriors' modes are nearly identical to best-estimates computed with CL. Statistical conclusions will be similar between BH, BL-AL and CL if, and only if, significance level ( $\alpha$ ) is corrected for multiple comparisons. Nevertheless only Bayesian allows null hypotheses acceptance and a clean ranking of the 6 microbiological methods using posterior densities within, below, and above ROPE limits. Using flat priors, it isn't surprising to find similarities between Bayesian and Classical methods. However, while avoiding classical paradigm misinterpretation issues, the Bayesian framework provides informative and meaningful results with no multiple comparison issues.

### **P03.0680. Patterns of E-Cigarette Use and Health Characteristics of E-Cigarette Users in Baltimore County**

Atul Aravindakshan

*Atul Aravindakshan<sup>1</sup>, Angela Aherrera<sup>1</sup>, Rui Chen<sup>1</sup>, Ana Rule<sup>1</sup>*

*1. Environmental Health and Engineering, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States.*

**Abstract:** Introduction: E-cigarettes have gained popularity among the youth with peak initiation risk at 14-15 years, and as a tool to combat tobacco addiction. Current scientific literature indicates that e-cigarettes are less harmful when compared to traditional cigarettes. However, emitted e-cigarette aerosol contains known toxins such as formaldehyde, toxic metals, and nicotine. Aim: To characterize vaping preferences and health characteristics of e-cigarette users in Baltimore County, USA Methods: 53 e-cigarette users and 50 non-users were recruited from Baltimore county. Information about demographics, patterns of e-cigarette use, other smoking habits, and dental and physical health were collected through questionnaires. Results: Majority of e-cigarette users were Caucasian (87%), male (72%) with a mean age of 28 years, and had consistently used e-cigarettes for a little less than 3 years. 85% of users reported the need to vape within the first hour of waking up, with 28% feeling the need within the first 5 minutes. The mean nicotine concentration of e-cigarette juice used was 6.5 mg/ml. Participants vaped an average of 45 ml of e-cigarette fluid per week and used a mean voltage setting of 4V. 50% of users intended to reduce nicotine concentration, and 51% planned to quit the use of e-cigarettes altogether. A preference for higher nicotine concentration with increase in age was observed; 0.37 mg/ml CI: (0.20,0.53) in the unadjusted model and 0.40 mg/ml CI: (0.22,0.57) when adjusted for sex, education level, race and smoking status. There was a higher prevalence of hypertension (21% vs 4%), history of wheezing (17% vs 2%), and shortness of breath (28% vs 12%) in e-cigarette users compared to non-users. There were no significant differences in other health characteristics reported. Conclusion: Our study describes patterns of e-cigarette use in Baltimore county, USA. Further research is required to understand the health effects of e-cigarette use.

## **P03.0690. Applying Low-Cost Sensors for Personal Particulate Matter and Noise Exposure Assessment**

Eelco Kuijpers

*Eelco Kuijpers<sup>1</sup>, Dora Cserbik<sup>1</sup>, Jan Vonk<sup>2</sup>, Anjoeka Pronk<sup>1</sup>, John Bolte<sup>2</sup>*

*1. TNO, Zeist, Netherlands.*

*2. National Institute for Public Health and the Environment (RIVM), Bilthoven, Netherlands.*

Abstract: Low-cost sensors offer the possibility to gain more insight into personal exposure. Compared to traditional methods, sensors provide more high resolution data in space and time. However, there is a gap in understanding how these devices perform and how they can be applied for actual prevention. The overall aim of this study was to examine the accuracy and precision of low-cost sensors for particulate matter (PM) and noise and to study their field application. Two different low-cost PM (OPC-N2, Alphasense; SDL607, Nova Fitness) and two low-cost noise sensors (Rion NL-27; Noise Sentry) were compared (concordance correlation coefficient (ccc)) to reference devices and relatively calibrated. Next, the low-cost sensors were deployed to measure personal exposure of construction, roadside and desk workers. In addition, observations and questionnaires were used to obtain contextual information. The OPC-N2 was strongly correlated for PM<sub>2.5</sub> (average ccc=0.78) while the SDL607 (data per 5 minutes) showed moderate correlations (average ccc=0.43) compared to a reference device. The field measurement demonstrated that construction workers had the highest exposure of PM<sub>2.5</sub> (N=5, median=13.68 µg/m<sup>3</sup>) compared to roadside (N=6, median=2.19 µg/m<sup>3</sup>) and desk workers (N=4, median=0.09 µg/m<sup>3</sup>). Average noise exposure varied between 62-79 dB and 74-87 dB for the Rion NL-27 and Noise Sentry, respectively. Furthermore, peaks in exposure for noise and PM 2.5 could be explained based on contextual information. In conclusion, the tested PM<sub>2.5</sub> and noise sensors showed rather accurate and precise results at least within sensor types, which could subsequently be used for real time prevention of high exposures. These sensor results highlight their importance of sensor technology as a promising tool with respect to the exposome concept aiming to measure the totality of a person's lifetime exposure.

**P03.0700. An Air Quality Modeling System Providing Smoke Impact Forecasts for Health Protection in Southeastern U.S.A.**

Armistead Russell

*2. Southern Research Station, US Forest Service, Athens, GA, United States.*

*3. Computer Science, Georgia Institute of Technology, Atlanta, GA, United States.*

**Abstract:** Background/Aim Prescribed fire is the leading source of PM<sub>2.5</sub> emissions in southeastern USA. We are developing the HiRes-X modeling system to forecast prescribed fire activity and its impacts on air quality and human health, and the Southern Integrated Prescribed Fire Information System (SIPFIS) to disseminate these forecasts, along with measures of social vulnerability and health impacts, for emergency planning and preparedness purposes. Methods HiRes-X uses innovative modeling and machine learning approaches to identify areas most impacted by prescribed fires. Specifically, a regression tree model is built using meteorology and prescribed fire data from recent years to generate highly resolved burn activity forecasts. Burn emissions are calculated using satellite enhanced fuel maps, consumption estimates and region specific emission factors. Community Multiscale Air Quality model is used to compute the contribution of burn emissions to local and regional air quality. HiRes-X modeling system is integrated with measures of cardiorespiratory health impacts and social vulnerability to identify communities vulnerable to smoke from prescribed fires. SIPFIS dashboard provides map and chart visualization tools that are built using open source software, and it features interactive capabilities to respond dynamically to user selections. Results Analyses that can be performed with SIPFIS include comparisons of burn activity forecast to burn permit records or satellite fire detections, and air quality forecast to observations. SIPFIS can be used for planning prescribed burning operations to reduce human exposure to fire smoke. Conclusions HiRes-X forecasting system incorporates new elements that can facilitate dynamic management of prescribed fires in southeastern USA. SIPFIS dashboard offers various analysis features that can be used to take preventive actions for minimizing the air quality and health impacts while reaping the ecological and economic benefits of prescribed burning.

### **P03.0710. Exploring the Use of Robots for Exposure Studies**

Elisabeth Cook

*Elisabeth Cook<sup>1</sup>, Kris Mohan<sup>1</sup>, Rahul Shome<sup>2</sup>, Kostas Bekris<sup>2</sup>, Jennifer Shin<sup>3</sup>, Clifford Weisel<sup>1</sup>*

- 1. Exposure Science, EOHSI, Rutgers University, Piscataway, NJ, United States.*
- 2. Computer Science, PRACSYS Lab, Rutgers University, Piscataway, NJ, United States.*

**Abstract:** Robots are becoming more incorporated into our society to perform routine tasks in research and the workforce. The attractive qualities of using robots include consistency, repetition, and longevity. This proof-of-concept study aimed to determine if robots are suitable to use for exposure predictions, by comparing the data to published human air painting data and/or model estimates, and to investigate the volatile organic compound (VOC) exposure from painting on drywall. A 2-arm smart robot was programmed to paint drywall for an average of  $64 \pm 11$  minutes in a controlled environmental facility. Temperature and relative humidity were kept constant at  $25 \pm 0.47$  °C and  $40 \pm 6$  %, respectively, to ensure uniform conditions and to control/measure the air exchange rate throughout the study. During the robotic painting session, the off-gassing of VOCs from paint was measured for both personal and area zones. VOC measurements were taken using passive and active air samplers, and direct-read monitors. Consistent results for the area painted for the front ( $60.1 \pm 2.5$  cm by  $77.5 \pm 0.85$  cm) and sides ( $60.1 \pm 2.5$  cm by  $60.1 \pm 2.9$  cm) and the amount of paint used per trial ( $1.53 \pm 0.65$  kg) suggest that using a robot to perform an exposure study was successful. Branched alkanes, acetone, and isopropanol were among the VOCs with the highest concentration detected in the active air samplers. For the resulting VOC concentrations, a direct correlation between amount of paint used and the total hydrocarbon concentration was observed. The average total hydrocarbon concentration measured was  $1.44 \pm 0.39$  ppm. The direct-read monitors followed the same trend at higher observed VOC concentrations of  $2.74 \pm 0.94$  ppm (right),  $1.74 \pm 0.56$  ppm (middle), and  $2.15 \pm 0.9$  ppm (left), compared to the total hydrocarbon measurements. Overall, a low VOC concentration ( $< 3$  ppm) was found indicating a low exposure for personal and area zones.

**P03.0720. Practical Aspects for Implementing Low Burden Particulate Matter Samplers in a Pediatric Cohort Asthma Intervention Study**

Maria Tchong-French

*Maria I. Tchong-French<sup>1</sup>, Elizabeth Torres<sup>2</sup>, Jennifer Krenz<sup>1</sup>, Lisa Younglove<sup>1</sup>, Catherine Karr<sup>1</sup>*

*2. Northwest Community Education Center/Radio KDNA, Granger, WA, United States.*

**Abstract:** An academic-community partnership is currently working on an intervention study (Home Air in Agriculture Pediatric Intervention - HAPI) to examine the effectiveness of High Efficiency Particulate Air (HEPA) cleaners to improve children health with asthma in a rural agricultural setting. We measured particulate matter (PM) concentrations (PM<sub>2.5</sub>, PM<sub>10</sub>) in indoor air before and after the implementation of the HEPA cleaners in the homes. We selected the RTI International MicroPEM (MP) samplers for measuring PM<sub>2.5</sub> and PM<sub>10</sub> concentrations due to their low subject burden (size/noise), low relative cost, and ease of use by community partners for field sampling (calibration/operational procedures). Implementing the MP samplers, originally personal monitors, into stationary monitors in low income homes with children, many with limited space presented practical challenges. We developed a low cost, readily mobile and "child proof" minimal profile sampler stand utilizing an intravenous pole with hooks that held a bird suet feeder. The MPs were placed inside the feeder. The stand provided an opportunity to hang other passive samplers (Ogawa) used in the study. Sporadic incomplete PM sampling by the MPs during our 2 week integrated sampling period were investigated through subject and field staff interviews and iSocket 3G power outage monitoring. We discerned child contact with on/off buttons and unplugging the devices explained most data loss. Simply placing lab tape over MP buttons and additional training for families has resulted in more complete sampling. Preliminary data from subjects with sampling conducted before and after HEPA air cleaner assignment demonstrate effectiveness in PM for intervention homes (% change) compared with control homes (%).

## **P03.0730. Patterns of Monthly Variation in Urban Ambient Nitrogen Dioxide Observed in a National Monitoring Network, Plus Implications for Exposure Assessment**

Ian Longley

*Ian Longley<sup>1</sup>, Ayushi Kachhara<sup>1</sup>*

*1. NIWA Ltd, Auckland, New Zealand.*

Abstract: Assessment of exposure to traffic-related air pollution (TRAP) is often based upon an observational campaign using a network of passive samplers, using nitrogen dioxide as a proxy for TRAP. These data are then frequently used as the input for a land-use regression model. However, such observational campaigns are frequently limited in time - in some cases only a single sample - and therefore the stability of the spatial variation observed in time is assumed. The New Zealand Transport Agency established a national monitoring network for NO<sub>2</sub> in 2007, with coverage expanded to over 120 sites in 2010. Passive samplers have been deployed at these sites every month for over a decade, allowing temporal patterns, and variation in patterns between sites, to be investigated. Analysis has revealed that all sites possess a persistent seasonal variation with concentrations peaking in winter and reaching a minimum in summer. The seasonal variation is more predictable at urban background sites with the amplitude of seasonal variation being proportional to the annual mean concentration. However, at sites close to major roads, intersections and within street canyons, seasonal variation is less in amplitude, but also subject to more random variation making it less predictable. Attempts to cluster sites using site metadata to predict differences in temporal variation were generally unsuccessful indicating either true randomness, or the absence of critical explanatory variables in the available metadata. Some sites revealed step-changes at certain points in time which may be related to step-changes in local traffic flows. A seasonal adjustment algorithm was created to predict annual mean concentrations based on sub-annual observational campaigns. The relationship between the length of a hypothetical short observational campaign and the error in the adjustment (and hence predicted annual mean concentration) as a function of site metadata was characterised.

### **P03.0740. How Far Are We from Having Air Quality in Navigation Apps?**

Qiang Yang

*Qiang Yang<sup>1</sup>, Zev Ross<sup>2</sup>, Jingya Bi<sup>1</sup>, Cara Smith<sup>1</sup>, Steven Chillrud<sup>1</sup>, Darby Jack<sup>3</sup>*

*1. Lamont-Doherty Earth Observatory, Columbia University, Palisades, NY, United States.*

*2. ZevRoss Spatial Analysis, Ithaca, NY, United States.*

*3. Environmental Health Sciences, Columbia University, New York, NY, United States.*

Abstract: Checking traffic using navigation apps has become the norm when we plan routes for car trips. A real-time air quality model with high spatial resolution built into route selecting navigation apps could greatly benefit people doing outdoor exercise or frequent commuting, in addition to the EPA's Air Quality Index (AQI) forecast (<https://www.airnow.gov/>) that uses data from federal reference or equivalent monitoring techniques typically at rather coarse spatial resolution, e.g. 10 sites in NYC. This real-time high-resolution air quality model is the long-term goal of the Map My Air project (<https://project.wnyc.org/map-my-air/>). In this pilot study, output of seasonal spatial surface of fine particulate matter (PM<sub>2.5</sub>) from a land use regression model based on bi-weekly data from the New York City Community Air Survey (originally 150 monitoring sites, now ~70) adjusted by hourly temporal variation provided from AirNow PM<sub>2.5</sub> levels is compared to 3-years of data collected by personal air monitors (RTI microPEM and Aethlabs microAeth AE51) from biking commuters in NYC at 1-minute and approximately 300 m resolution. Model outputs show a median PM<sub>2.5</sub> concentration of 11.6 µg/m<sup>3</sup>, a good agreement with personal monitor observation data of 11.7 µg/m<sup>3</sup>, but show a much smaller range of predicted PM<sub>2.5</sub> (6.6 - 21.5 µg/m<sup>3</sup>, IQR 10.1 - 13.4 µg/m<sup>3</sup>) in comparison to that of observation (0.5 - 710 µg/m<sup>3</sup>, IQR 7.7 - 18.1 µg/m<sup>3</sup>) and a very weak correlation with observation data due to the inherent incapability of this simple model in predicting extreme values. Real-time traffic data and meteorology data will be added together with the personal air monitor observation data to refine the model's spatial resolution to street level and improve its temporal sensitivity to sub-hour level.

### **P03.0750. Exposure to Fine Particles and PAHs in Pizza Restaurants with Wood-Fired Ovens**

Pernilla Almerud

*Pernilla Almerud<sup>1</sup>, Gunilla Runström Eden<sup>1</sup>, Sandra Johannesson<sup>1</sup>*

*1. Occupational and Environmental Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden.*

**Abstract:** Introduction Some restaurants use wood-fired ovens for cooking and baking, e.g. pizzerias. The aim was to measure exposure to fine particles for the workers and in the restaurants. Methods Measurements were performed at seven restaurants (2 days, 8 hr). The ovens were located in a working area in the restaurants. Personal exposure to fine particles (PM<sub>2.5</sub>) and particulate polycyclic aromatic hydrocarbons (PAHs) were measured on two workers at each restaurant. PM<sub>2.5</sub> was collected on teflon filter. Mass concentration was determined gravimetrically and analyzed for PAHs using GC-MS in SIR mode. One of the workers also wore a personal sampler for black carbon (BC), MicroAeth Model AE51. Stationary sampling equipment were placed near the oven and near the dining tables. In addition, size-fractionated particle samples (five size ranges including >2.5, 1.0-2.5, 0.50-1.0, 0.25-0.50, and < 0.25 µm) were collected near the oven using a Sioutas Cascade Impactor. Particle number concentration (PNC), 10-1000 nm, was measured with a Condensation Particle Counter (CPC3007). Results Median personal exposure to PM<sub>2.5</sub> and B(a)P for 26 workers were 27 µg/m<sup>3</sup> (range: 13-76 µg/m<sup>3</sup>) and 0.13 ng/m<sup>3</sup> (range: 0.01-2.6 ng/m<sup>3</sup>), respectively. Stationary levels were similar to personal exposure. No significant difference was found between concentrations near the ovens and the dining area. The majority of the B(a)P (>95%) was found in the two finer stages (0.25-0.50, and <0.25 µm). Out of that, in average 78% was found in the finest stage. Median BC exposure varied between 0.5 and 4.1 µg/m<sup>3</sup> and was higher during lunch and evening rush hours. The PNC varied across a wide range between the restaurants, with means from about 20 000 up to 170 000 part/cm<sup>3</sup>. Conclusions The exposure to B(a)P were well below OEL. Almost all B(a)P was associated with PM<sub>0.25</sub>. Particles generated from the wood-fired ovens gave rise to high number concentrations; however, the measured particles mass concentrations were low.

**P03.0760. The Impacts of Energy-Efficient Interventions on Population Health, Indoor Environmental Health, and Energy Costs: A Simulation Study of Multifamily Housing**

Lindsay Underhill

*Lindsay J. Underhill<sup>1</sup>, William S. Dols<sup>2</sup>, M. Patricia Fabian<sup>1</sup>, Jonathan Levy<sup>1</sup>*

*1. Department of Environmental Health, Boston University School of Public Health, Boston, MA, United States.*

*2. Engineering Laboratory, National Institute of Standards and Technology, Gaithersburg, MD, United States.*

**Abstract:** **BACKGROUND.** Residential energy-efficiency measures such as weatherization and ventilation improvements can have important impacts on direct energy utilization, resident health outcomes associated with indoor air quality (IAQ), and general population health influenced by ambient air quality. The development of flexible, analytical tools to examine the potential trade-offs among these impacts is essential for the identification of retrofits that are energy-saving and health protective, yet no study to date has modeled all three of these dimensions together. **METHODS.** We estimated the impacts of energy and ventilation retrofits in a set of typical gas-heated midrise multifamily buildings in the U.S. using a combination of 1) novel IAQ-energy co-simulation modeling (CONTAM/EnergyPlus), 2) energy-to-emissions modeling for power plants (AVERT) and residential combustion, 3) fine particulate matter (PM<sub>2.5</sub>) health impact assessment using co-simulation IAQ outputs and regional-scale atmospheric dispersion model (CMAQ-DDM) outputs, and 4) health outcome monetization. **DISCUSSION.** Interventions that combined weatherization and ventilation measures provided energy savings, resident health benefits, and general population health benefits that varied by intervention type, performance level, season, and location. General population health benefits were approximately 8% of direct economic savings and the ratio between population health benefits and economic savings was approximately 1.5 to 3 times greater for electricity than for residential combustion. Interventions without ventilation improvements led to increases in indoor PM<sub>2.5</sub> and associated monetized indoor environmental health disbenefits that greatly outweighed direct energy savings and population health benefits. Results emphasize the importance of holistic energy-efficient interventions that explicitly consider IAQ and our analytical framework can be used to inform health-protective residential energy-efficiency policy.

### **P03.0770. The Sky's the Limit: 3D Air Pollution Sensing Using Drones**

Drew Michanowicz

*Drew R. Michanowicz<sup>1</sup>, Jonathan Buonocore<sup>1</sup>, Jose Vallarino<sup>1</sup>, Qiyun Gao<sup>3</sup>, Lance Li<sup>2</sup>, Joseph G. Allen<sup>1</sup>, Aaron S. Bernstein<sup>4</sup>*

- 4. Division of Pediatrics, Boston Children's Hospital, Boston, MA, United States.*

Abstract: Current air quality monitoring networks rely on stationary sites, which do not effectively capture transient and localized pollutants such as methane leakage and anthropogenic volatile organic compounds (VOCs). Drones carry the potential to transform how communities, regulators and industry quantify emissions and air quality impacts. Air quality monitoring using drones addresses two fundamental challenges: 1) the inability to monitor directly at source and in the vertical plane, and 2) real-time, 3D pollutant dispersion tracking. While these dynamic systems can provide novel data streams; they intrinsically cannot be as specified, controlled, or reproducible as traditional methods. Therefore well-defined data interpretation approaches and substantial data quality assurances are needed. Here we present system architecture, functionality, technical challenges, legal aspects, and quality assurances related to a multi-air pollutant sensing drone platform. System architecture encompasses the drone, the multi-air pollutant module (MAPM), and communication data links. The MAPM is equipped with active measures of carbon monoxide (CO), nitric oxide (NO), nitrogen dioxide (NO<sub>2</sub>) using Alphasense B4 sensors. In response to sensor limitations, a remotely controlled grab sampling protocol was developed with up to eight remotely controlled 0.2L sample bags for post-hoc chemical analyses (VOCs, and methane). To support pollutant-tracking and grab-sample source apportionment capabilities, real-time wind speed and direction algorithms were developed by reverse engineering on-board telemetry diagnostics (e.g., pitch, yaw, and roll). As drone technology continues to mature alongside real-time gas sensing technologies, these techniques can complement traditional methods of stationary-site air quality monitoring. Over time we anticipate aerial air quality monitoring to overcome intrinsic limitations and play a significant role in shaping the future of air quality and exposure assessment.

## **P03.0780. Mobile-Monitoring of Air Pollution (Black Carbon): Preliminary Results from Bangalore, India**

Meenakshi Kushwaha

- 4. Center for Study of Science, Technology and Policy, Bangalore, India.*

**Abstract:** INTRODUCTION India is home to some of the world's most polluted cities. Stationary monitoring generally does not provide information about local variations in air pollution concentrations. We conducted a pilot study in Bangalore, India to explore the potential for mobile monitoring to provide high-resolution exposure data in Indian cities. METHODS Our aim is to over-sample a small area, thereby shedding light on the how many mobile-monitoring measurements are needed to get a robust estimate of concentrations at each location. We conducted measurements using a motorcycle equipped with an aethalometer for black carbon (BC). Our study area includes mixed income neighbourhoods and an adjoining highway, with a total riding distance of ~45 km per day. Roads include small streets and alleys in each neighborhood. Raw BC measurements were corrected for two common measurement artifacts. RESULTS To date, we have collected 20 h of repeated measurements. The overall median BC concentration on all roadways was 16  $\mu\text{g}/\text{m}^3$  (highways vs. surface streets: 67 vs. 15  $\mu\text{g}/\text{m}^3$ ). Preliminary results suggest that the initial dataset is sufficient to obtain robust estimates of spatial variability in concentrations. Planned additional monitoring will help confirm that finding for the study location and for additional neighborhoods.

**P03.0790. Development of Air-Bot Samplers: Community Networks of Inexpensive Sensors as Sentinels to Trigger Air-Sampling Methods**

Matt Karwowski

Abstract: Air-Bots are automated samplers with inexpensive sensors that find hotspots in which to sample. The Air-Bots use Wi-Fi/Bluetooth-capable microcontrollers capable of turning on sampling pumps or opening and closing evacuated canisters. The sensors are semi-quantitative, allowing for the mapping of relative hotspots. Community residents can permit Air-Bots to use their Wi-Fi to report the data. Should the network identify a hotspot, the closest Air-Bot will start a sampler and report that sampling has begun -for us to pick up to analyze. The Air-Bot network reduces the number of samples compared to monitors with threshold value triggers only. The continual data reporting allows us to abort some sampling because the event is too short-lived to warrant laboratory analysis. They allow for data reporting in-between investigations and are inexpensive enough to leave behind. We developed two teams of Air-Bots, odor-based and particulate-based. The odor-based Air-Bot teams use calibrated ammonia and hydrogen sulfide sensors linked to a solenoid atop an evacuated canister. They currently capture grab samples to identify the chemicals associated with elevated odor events. Another design is to locate the sensor close to the source of pollution with the sampler at a downwind residence. The particulate-based Air-Bots use optical sensors chosen for specific situations. They are linked to a personal sampling pump and filter for particulate analysis. One sensor is well-suited to trigger respirable quartz samples. The network can retain and map real-time data from multiple Air-Bots. Data from each Air-Bot can be re-animated to identify events that need further processing. Air-Bot sensor data correlate well measurements. The continuous stream of data helps identify movement of PM plumes while the quartz measurements are to compare with health-based time-weighted averages.

### **P03.0800. Evaluation of Two Low-Cost PM Monitors (Dylos and Speck) Against Dusttrak DRX for Monitoring Urban PM Concentrations in Astana, Kazakhstan and Tehran, Iran**

Aigerim Makso

*Mehdi Amouei Torkmahalleh<sup>1</sup>, Fatemeh Mohammaddezhashibi<sup>1</sup>, Hamed Sharifi<sup>2</sup>, Yousef Rashidi<sup>3</sup>, Parya Broomandi<sup>2</sup>, Mohammadhossein Forouzi<sup>2</sup>*

*1. Chemical and Aerosol Research Team, Chemical Engineering, Nazarbayev University, Astana, Kazakhstan.*

*2. Air Pollution Monitoring Department, Sky Aerosol Monitoring (Rizgard Payesh Asman) LLP, Tehran, Iran (the Islamic Republic of).*

*3. Environmental Sciences Research Institute, Shahid Beheshti University, Tehran, Iran (the Islamic Republic of).*

**Abstract:** Since the availability of low-cost monitors, researchers have investigated possible correlations with low-cost PM monitors and respective well referenced high-cost monitors. In the present study two low cost instruments were used to examine the air quality. A Dylos DC1700 (a low-cost equipment), and a Speck (Specksensor). Dylos monitors the particle number concentrations in two sizes, larger than 0.5  $\mu\text{m}$  (hereinafter called small size) and larger than 2.5  $\mu\text{m}$  (hereinafter called larger size). Speck provides PM<sub>2.5</sub> mass concentration. A DustTrak DRX Model, TSI, USA was employed to measure PM mass concentrations (PM<sub>1</sub>, PM<sub>2.5</sub>, PM<sub>4</sub>, PM<sub>10</sub>, Total particles). We have evaluated Dylos and Speck against Dusttrak DRX individually for different indoor and outdoor sources. Three PM sources including mixed grilling (ground beef meat), construction particles, and outdoor PM in a rural area, Borovoye, Kazakhstan, and smoking particles at Middle East Technical University Northern Cyprus Campus were examined to evaluate the performance of Dylos against Dusttrak. For Mixed Grilling and Construction source, the correlation coefficient values for fine and coarse fractions were found to be 0.61 and 0.66, respectively. This moderate correlation could be due to the presence of significant amount of coarse size particles that can be detected by Dylos. Combining all smoking data, poor correlation values for fine ( $R^2 = 0.17$ ) and coarse ( $R^2 = 0.20$ ) particles were obtained. Poor correlation coefficient values were observed for both fine ( $4 \times 10^{-5}$ ) and coarse ( $6.1 \times 10^{-3}$ ) particles during the monitoring of outdoor PM in Borovoye. Speck was compared with Dusttrak DRX for commuting PM in Astana city. We are now analyzing the data. For ISES 2018, we are aimed to evaluate the performance of these two low-cost PM monitors against DustTrak DRX by running the monitors in Tehran, Iran for three weeks during May 2018 and in Astana, Kazakhstan for 8 weeks during June-August 2018.

### **P03.0820. The Source Identification of Indoor Fine Particulate Matter Based on Infiltration Factor of Beijing Residence**

Chunyu Xu

*Chunyu Xu<sup>1</sup>, Na Li<sup>1</sup>, Qin Wang<sup>1</sup>, Dongqun Xu<sup>1</sup>*

*1. National Institute of Environmental Health, Chinese Center for Disease Control and Prevention, Beijing, Beijing, China.*

**Abstract:** Objective To quantify the contribution of ambient and indoor-generated PM<sub>2.5</sub> to indoor air in residential environments in Beijing, and to explore the influencing factors of indoor-generated PM<sub>2.5</sub>. Methods A total of 55 residents in Beijing were selected. The indoor and outdoor PM<sub>2.5</sub> were monitored in both non-heating (n=43) and heating seasons (n=45) for 7 consecutive days. The mass concentrations of PM<sub>2.5</sub> were measured by gravimetric method, while elemental concentrations of sulfur in filter deposits were determined by energy-dispersive X-ray fluorescence spectrometry. PM<sub>2.5</sub> infiltration factor was estimated as the indoor/outdoor sulfur ratio. The concentrations of ambient and indoor-generated PM<sub>2.5</sub> were calculated according to mass balance equation. The questionnaire was used to collect the general characteristics of the residences and the indoor activities of the occupants. Multiple linear regression model was used to explore the influencing factors of indoor-generated PM<sub>2.5</sub>. Results In both seasons, the majority of indoor PM<sub>2.5</sub> was of ambient origin [81%±21% (Median=83%) in non-heating season and 75%±24% (Median=77%) in heating season], and the seasonal differences were not statistically significant (P=0.230). Indoor generated PM<sub>2.5</sub> concentrations in non-heating season were 12.8±16.4µg/m<sup>3</sup> (M=8.4µg/m<sup>3</sup>) which were slightly lower than the responding values 22.2±32.9µg/m<sup>3</sup> (M=10.4µg/m<sup>3</sup>) in heating season (P=0.226). During non-heating season, indoor smoking and hours of window opening were associated with indoor generated PM<sub>2.5</sub>, which can explain the 27% of total variations across residences, while the indoor smoking was the only factor identified in multiple regression model during heating season, which could explain 25% of total variations across residences. Conclusion the indoor PM<sub>2.5</sub> levels in residents of Beijing are mainly from outdoor air. Reducing indoor smoking and increasing window ventilation can effectively reduce the exposure to indoor-generated PM<sub>2.5</sub>.

**P03.0830. The IVAIRE Study: Inter- and Intra-Seasonal Variations in VOC's Measured in Canadian Homes with Asthmatic Children during a Intervention Field Study**

Daniel Aubin

*Daniel G. Aubin<sup>1</sup>, Doyun Won<sup>1</sup>, Hans Schleibinger<sup>1</sup>, Pierre Lajoie<sup>2</sup>, Denis Gauvin<sup>2</sup>, Jean-Marc Leclerc<sup>2</sup>*

*2. Institut national de santé publique du Québec, Quebec City, QC, Canada.*

**Abstract:** A randomized intervention study was done to measure the impact of improved ventilation on indoor air quality (IAQ) and the respiratory health of asthmatic children in Québec City. The intervention involved the installation of a Heat or Energy Recovery Ventilator while a comprehensive suite of environmental parameters were used to characterize the IAQ. The IAQ measurements were taken during three separate periods both before and after the intervention. The winter measurements, used to correlate ventilation rates with IAQ and respiratory health, were taken twice to account for intra-seasonal variations in IAQ while the single summer measurement was taken to determine the inter-seasonal variations. A cohort of 111 asthmatic children were enrolled for the pre-intervention phase of which 83 were selected to participate in the subsequent intervention phase because their homes were found to be under-ventilated (air exchange rate <0.30 h<sup>-1</sup>). The children were then randomized into an intervention (n=43) and control (n=40) group for the second year (post-intervention phase) of the study. This paper presents the variations in the VOC's measured within the same season, between seasons (winter, summer), along with the year-over-year variations within the same season. A statistically significant seasonal variability was observed for relative humidity, NO<sub>2</sub>, VOC's and aldehydes. The aromatic and aliphatic hydrocarbons were most elevated in winter, up to 2x higher, and were the most strongly impacted by the ventilation intervention. The aldehydes, oxygenated VOC's, and NO<sub>2</sub>, all had higher summertime concentrations despite the median air exchange rate being almost twice as high during summer. A possible explanation could be that the increased temperature and humidity encountered in summer would promote the release of aldehydes from hydrolysis reactions and off-gassing from construction and consumer products and that ambient formaldehyde is generally higher in summer.

### P03. Air Pollution 3

#### **P03.0860. Prenatal Particulate Air Pollution and the Incidence of Childhood Cancers: Identifying Critical Windows and Differences by Regional Oxidative Potential**

Eric Lavigne

*Eric Lavigne<sup>1</sup>, Rick Burnett<sup>1</sup>, Dave Stieb<sup>1</sup>, Greg Evans<sup>3</sup>, Krystal J. Pollitt<sup>2</sup>, Hong Chen<sup>1</sup>, Antonio Gasparrini<sup>4</sup>, Scott Weichenthal<sup>5</sup>*

- 1. Health Canada, Ottawa, ON, Canada.*
- 2. Department of Environment Health Science, Yale University, New Haven, CT, United States.*
- 3. University of Toronto, Toronto, ON, Canada.*
- 4. Department of Social and Environmental Health Research, London School of Hygiene & Tropical Medicine, London, United Kingdom.*
- 5. McGill University, Montreal, QC, Canada.*

**Abstract:** Background: Studies have reported associations between prenatal exposure to fine particulate air pollution (PM<sub>2.5</sub>) and the incidence of early childhood cancers. However, few studies have examined specific windows of vulnerability and possible effect modification by PM<sub>2.5</sub> oxidative potential. The aim of this study was to identify sensitive windows for the effects of PM<sub>2.5</sub> on childhood cancer development and whether regional differences in the oxidative potential of PM<sub>2.5</sub> modified the associations. Methods: Our cohort consisted of ~1.5M singleton live births occurring between 1998 and 2015 in 31 cities in the province of Ontario, Canada. PM<sub>2.5</sub> from ground monitors were collected and city-level PM<sub>2.5</sub> oxidative potential were measured. Incident cases of specific paediatric cancers among children up to age 6 were ascertained through administrative health data linkages. Using distributed lag models (DLMs), we examined associations between weekly averaged PM<sub>2.5</sub> levels over pregnancy and childhood cancer incidence. We used random effects meta-analysis to combine the estimates of effect from regression models across cities on childhood cancer incidence and used meta-regression to evaluate the modifying effect of PM<sub>2.5</sub> oxidative potential. Results: We identified 1,644 incident childhood cancer cases. An interquartile increase (2.6 µg/m<sup>3</sup>) in PM<sub>2.5</sub> levels at weeks 4-13 were positively associated with an increased risk of astrocytoma in the highest quartile of glutathione-related oxidative potential (OR = 1.34; 95% CI: 1.15, 1.51), but not the lowest quartile (OR = 0.99; 95% CI: 0.81, 1.22; p-interaction = 0.03). We did not observe associations for other cancer types. Between-city differences in ascorbate related oxidative potential did not significantly modify associations of cancer subtypes with PM<sub>2.5</sub>. Conclusions: Between-city differences in glutathione-related oxidative potential may modify the impact of PM<sub>2.5</sub> on the risk of a specific type of brain tumor in children.

**P03.0870. Annual Average PM2.5 Exposure Is Associated with Mortality in a Heart Failure Cohort: Results from the EPA CARES Study**

Cavin Ward-Caviness

*Cavin Ward-Caviness<sup>1</sup>, Anne M. Weaver<sup>1</sup>, Emily Pfaff<sup>2</sup>, Lucas Neas<sup>1</sup>, Robert Devlin<sup>1</sup>, Wayne Cascio<sup>1</sup>, David Diaz-Sanchez<sup>1</sup>*

*1. National Health and Environmental Effects Research Laboratory, US Environmental Protection Agency, Chapel Hill, NC, United States.*

*2. University of North Carolina - Chapel Hill, Chapel Hill, NC, United States.*

Abstract: As part of the EPA CARES study, we extracted electronic health records (EHRs) on 41,000 heart failure (HF) patients seen at a University of North Carolina affiliated hospital from 01/01/2004 through 12/31/2016. After data cleaning and restricting to those residing in North Carolina we were left with a study cohort of 37,206 individuals. Over an average follow-up time of 2.25 years (83,895 person-years total follow-up time), we observed 9690 (26.0%) natural cause (non-accidental, non-homicidal) deaths. Information on annual average PM2.5 exposure was taken from ground-based monitors operated by the Environmental Protection Agency. Cox proportional hazards models were used to model the association between natural cause mortality and PM2.5 exposure while adjusting for age, sex, race, Hispanic ethnicity, the distance to the nearest monitor, and neighborhood characteristics. Results are given in terms of the hazard ratio (HR) per 1 µg/m<sup>3</sup> increase in PM2.5 and the associated 95% confidence interval (CI). In CARES, annual average PM2.5 exposure was associated with a substantial elevated mortality risk (HR = 1.24, CI = 1.23, 1.26); results which were consistent when restricting to those within 30 km of a monitoring station (HR = 1.22, CI = 1.21, 1.24). This association was strongest in those with diagnosed HF before the age of 50 (HR = 1.31, CI = 1.26, 1.36). As compared to individuals residing in areas below the National Ambient Air Quality Standard of 12 µg/m<sup>3</sup> for PM2.5, individuals in areas exceeding 12 µg/m<sup>3</sup> had an elevated mortality risk (HR = 2.72, CI = 2.60, 2.86). Long-term PM2.5 exposure is associated with a substantial mortality risk in individuals with pre-existing HF, particularly those diagnosed before age 50. Residing in areas with annual average PM2.5 above 12 µg/m<sup>3</sup> may impart substantial mortality risk for those with HF as compared to residing in areas below this level. This abstract does not necessarily reflect the policies of the U.S. EPA

### **P03.0880. Long-Term NO<sub>2</sub> Exposures and Cause-Specific Mortality in American Older Adults**

Ki-Do Eum

*Ki-Do Eum<sup>1</sup>, Bingyu Wang<sup>2</sup>, Justin Manjourides<sup>3</sup>, Fatemeh Kazemiparkouhi<sup>1</sup>, Vivian C. Pun<sup>4</sup>, Virgil Pavlu<sup>2</sup>, Helen Suh<sup>1</sup>*

**Abstract:** The impact of long-term exposure to nitrogen dioxide (NO<sub>2</sub>) on all-cause mortality and cause-specific mortality is poorly understood. We examined the association between long-term NO<sub>2</sub> exposure and cause-specific mortality among about 14 million Medicare beneficiaries living close to US Environmental Protection Agency air quality monitoring sites in the conterminous US from 2000 to 2008. After controlling for age, gender, race, and state, we found significant positive associations between 12-month NO<sub>2</sub> exposure and all-cause mortality [Hazard Ratio (HR): 1.06; 95%CI: 1.06, 1.06; per 10 ppb]. Additionally, long-term NO<sub>2</sub> exposure was associated with the three most common causes of death: mortality from cardiovascular (1.14; 95%CI: 1.14, 1.14) and respiratory disease (1.05; 95%CI: 1.04, 1.06) and from cancer (1.02; 95%CI: 1.02, 1.02). Twelve-month moving average NO<sub>2</sub> exposure was also associated with increased mortality from ischemic heart disease (1.22; 95%CI: 1.18, 1.20), cerebrovascular disease (1.10; 95%CI: 1.10, 1.10), and pneumonia (1.24; 95%CI: 1.24, 1.25). As expected, NO<sub>2</sub> was not positively associated with accidental mortality risk. When we additionally adjusted for county level behavioral variables (using the BRFSS data), we found similar patterns of association. When we extended our analysis to the 64 million beneficiaries living in the conterminous US from 2000 to 2008 as a sensitivity analysis, we similarly found association between long-term NO<sub>2</sub> exposure-associated mortality from all-cause, and cause-specific mortality. In our large cohort of U.S. Medicare beneficiaries, we provide additional evidence of the increased risk posed by long-term NO<sub>2</sub> exposures on mortality from all-causes, cardiovascular and respiratory disease, and cancer and provide new evidence of the impact of long-term NO<sub>2</sub> exposure on pneumonia.

**P03.0890. Evaluation of a Method to Indirectly Adjust for Unmeasured Covariates in Large Administrative Data Cohort Analyses: An Analysis of Associations between Fine Particulate Matter and Mortality in the 2001 Canadian Census Health and Environment Cohort (2001 C**

**Abstract:** Background. The method of indirect adjustment for unmeasured confounding is a promising technique in large cohort studies, however no formal evaluation of non-linear survival models has been conducted. Objectives: To describe and evaluate the indirect adjustment method for air pollution -mortality relationships with a large longitudinal cohort, the 2001 Canadian Census Health and Environment Cohort (CanCHEC, N=2.4 million), and a representative matching dataset (pooled cycles of the Canadian Community Health Survey, [CCHS], N=450,000) with detailed behavioural risk factor information. Methods: We compared the distribution of exposure to fine particulate matter (PM<sub>2.5</sub>) among subjects across multiple characteristics (age, sex, etc.), and examined the direction and magnitude of correlations amongst variables common to both datasets. We assessed the performance of indirect adjustment on non-linear Cox proportional hazard models by comparing estimates in the CanCHEC with and without indirect adjustment for known variables. Further, we estimated the degree of bias correction by removing variables available in both the CCHS and CanCHEC (e.g. education, income) and evaluated differences. Results: At baseline PM<sub>2.5</sub> distribution profiles across population characteristics were similar in both cohorts. PM<sub>2.5</sub> levels for CCHS participants tended to consistently be 1.8-2.0 µg/m<sup>3</sup> lower than the CanCHEC cohort, likely due to sampling differences between urban and rural areas since applying a sample-weighting scheme to the CCHS largely corrected for this discrepancy. Initial non-linear validation tests indicate possible underestimation of the PM<sub>2.5</sub> association with further testing on-going. Conclusions: Formal evaluation using a large longitudinal mortality cohort and representative health survey will help establish protocols that other jurisdictions can use to assess the viability of the indirect adjustment method when information on potential confounding variables are not available.

**P03.0900. Spatiotemporal Continuous Estimates of PM2.5 Concentrations in China, 2000-2016: A Machine Learning Method with Inputs from Satellites, Chemical Transport Model, and Ground Observations**

Tao Xue

*Tao Xue<sup>1</sup>, Yixuan Zheng<sup>2</sup>, Tong Zhu<sup>1</sup>, Qiang Zhang<sup>2</sup>*

*1. Peking University, Beijing, China.*

*2. Tsinghua University, Beijing, China.*

**Abstract:** Background: Exposure to ambient PM2.5 is known to harm public health in China. Satellite aerosol optical depth (AOD) were statistically associated with in-situ observations after 2013 to predict PM2.5, while the lack of monitoring data before 2013 created difficulties in historical estimates. Hindcast approaches using chemical transport models (CTM) can overcome this limitation, but still suffer incomplete coverage due to missing AOD or limited accuracy due to uncertainties of CTM. Objects: We attempted to produce historical PM2.5 estimates with complete spatiotemporal coverage and improved accuracy for exposure assessments in short- and long-term. Methods: First, we designed a machine learning (ML) model, which linked in-situ PM2.5 with high-dimensional expansion of numerous predictors (AOD, CTM outputs and etc.). To interpolate the missing predictions due to incomplete AOD, we incorporated another generalized additive model in next stage. Results: Cross-validations show that ML estimates were highly correlated with in-situ PM2.5, with R2 of 0.61, 0.68, and 0.75 for daily, monthly and annual averages, respectively. The two-stage estimates sacrificed accuracy on daily timescale (R2=0.55), but achieved complete spatiotemporal coverage and improved the accuracy of monthly (R2=0.71) and annual (R2=0.77) averages. The model was used to predict daily PM2.5 across China during 2000-2016 and estimate long-term trends for the period. The population-weighted PM2.5 significantly increased, by 2.10 (95% confidence interval [CI]: 1.74, 2.46)  $\mu\text{g}/\text{m}^3/\text{year}$  during 2000-2007, and rapidly decreased by 4.51 (3.12, 5.90)  $\mu\text{g}/\text{m}^3/\text{year}$  during 2013-2016. Conclusions: The data products could support large-scale epidemiological studies and risk assessments of PM2.5 in China.

### **P03.0910. Prevalence of Lung Function Abnormalities Following the Fort McMurray Wildfires**

Chung-Wai Chow

**Abstract:** Air pollution contributes significant to the burden of respiratory diseases. Vehicular, industrial and increasingly, wildfire emissions are major sources of air pollution in Canada. Increased symptoms, hospitalizations and mortality immediately after wildfires are known; the long-term health impact have not been studied. The devastating 2016 Fort McMurray (FMM) wildfires forced the months-long evacuation of the entire town and destroyed many homes. Most residents returned several months later, choosing to stay and rebuild. The long-term health impact of wildfires, and the ongoing exposure to resuspended residual wildfire ash are not known. Our study aims to assess the long-term impact on lung health in the permanent residents of FMM. We report on the health status of the first 45 participants (26F, 19M; mean age=45±2 yrs, range 21-71 yrs) at 18 months after the onset of the fires. Target enrolment is 200 with follow-up of at least 5 years. All 45 are permanent residents (mean residency=16±12; range 3-46 yrs). 13 worked in the oils sands; 5 are current smokers and 18 ex-smokers. Spirometry revealed a higher than expected prevalence of airflow obstruction; 11% had an FEV1 (forced expiratory volume in 1 sec)/FVC (forced vital capacity) ratio 1/FVC1/FVC<72.5%. 31% reported intermittent cough±sputum. Two had childhood asthma; only one is treated with inhaled steroids. One participant had COPD, treated with inhaled bronchodilators. The cohort was generally healthy with only 4 participants reporting underlying medical diseases other than lung disease. They were, however, obese with mean BMI=31±1. Our preliminary analyses found a higher than anticipated burden of unrecognized lung disease. Development of disease in this generally healthy young population will have significant social and public health impact in Canada.

## **P03.0920. An Analysis of Critical Air Quality Episodes in Santiago, Chile: Episode Prediction Modeling and Benefit-Cost Analysis**

*3. U.S. Environmental Protection Agency, RTP, NC, United States.*

**Abstract:** In January 2017, the United States Environmental Protection Agency (USEPA) and Chilean Ministry of Environment (MMA) launched the Megacities Partnership to advance air quality management in the Santiago metropolitan region. A goal of this partnership is to assess the effectiveness of MMA's critical episode management system, which restricts polluting activities in anticipation of air quality 'episodes', or days when PM<sub>2.5</sub> concentrations are forecasted to be above a certain threshold concentration. Each day during Chilean winter, MMA must predict whether the next day's PM<sub>2.5</sub> concentrations will exceed a threshold concentration for an episode to be declared. The MMA uses monitored air quality, modeled air quality, and meteorological data to predict episode status for the next day and recommends to the local government whether to initiate PM<sub>2.5</sub> emissions mitigation policies. We created logistic regression models using data available to the MMA team at the time the recommendations are made to understand which set of variables best predicts an air quality episode. We found that maximum monitored PM<sub>2.5</sub> concentration in the region, wind speed, specific humidity, the temperature differential between high and low elevation points in the city, and separately modeled air quality predictions (using WrfChem or Meteodata) are predictive variables that should be considered by the MMA episode declaration team. We also calculate health-related economic benefits and costs associated with instituting these emissions mitigation measures using EPA's BenMAP-CE model. We find that the mortality and morbidity-related economic benefits associated with declaring an episode offset the industrial, residential, and transportation costs of implementing the episode.

### **P03.0930. Hourly Associations between Ischemic Cardiac Events and Ambient Particulate Air Pollution: Does the Geographical Origin of the Particles Matter?**

Ronit Nirel

*Ronit Nirel<sup>1</sup>, Ilan Levy<sup>2</sup>, Sara Adar<sup>3</sup>, Bella Vakulenko-Lagun<sup>4</sup>, Alon Peretz<sup>5</sup>, Michal Golovner<sup>6</sup>, Uri Dayan<sup>1</sup>*

*5. Rabin Medical Center, Petah Tiqua, Israel. 6. SHL Telemedicine, Tel Aviv, Israel.*

**Abstract:** Introduction. Most of the studies linking cardiovascular disease with particulate matter (PM) exposures have focused on particle size and mass concentration. However, it has been increasingly recognized that it is important to also consider chemical composition. Examining the paths of air masses can provide insight into particle composition. The geographical location of Israel makes it susceptible to PM transport from distinct and diverse sources, thus making it an ideal place for back-trajectory analyses. We hypothesized that the air mass origin modifies the association between hourly PM exposure and acute ischemic events. Methods. Using telemedicine data, we conducted a case-crossover study of 1,855 confirmed ischemic cardiac events in Tel Aviv and Haifa, Israel (2005-2013). Ambient PM<sub>2.5</sub> and PM<sub>10-2.5</sub> concentrations during the hours before event onset were compared with matched control periods. We calculated 72-hr back-trajectories and divided them into 12 classes by their geographical origin and season. Results. Overall we found a 1.013 (95% confidence interval (CI): 0.981-1.046) and 1.003 (95% CI: 0.994-1.013) increased odds of an ischemic event for a 10 µg/m<sup>3</sup> increase in the 6-hr average of PM<sub>2.5</sub> and PM<sub>10-2.5</sub> respectively. The associations for PM<sub>2.5</sub> were strongest for air masses originating from Sinai and Egypt, with respective 1.29 (95% CI: 1.14-1.46) and 1.28 (95% CI: 1.08-1.52) greater odds for an ischemic event per 10 µg/m<sup>3</sup> increase in the previous 6 hours. For PM<sub>10-2.5</sub> the estimates were largest for air masses arriving from Europe on summer days (odds ratio (OR)=1.48, 95% CI: 1.09-2.02) and for Arabian Desert trajectories (OR= 1.07, 95% CI: 1.02-1.13) for the 6-hr averages. Conclusions. Our study suggests that sub-daily associations between PM and ischemic cardiac events are modified by the geographical origins of the particles. These findings may be translated to warnings of the population using e.g. available information on synoptic systems.

## **P03.0960. Traffic Density and Mortality Risk in the 1991 Canadian Census Health and Environment Cohort (CanCHEC)**

Sabit Cakmak

*Sabit Cakmak<sup>1</sup>, Chris Hebbern<sup>2</sup>, Jennifer Vanos<sup>4</sup>, Dan L. Crouse<sup>3</sup>*

**Abstract:** Background: There is evidence that local traffic density and living near major roads can adversely affect health outcomes. We aimed to assess the relationship between local road length, proximity to primary highways, and cause-specific mortality in the 1991 Canadian Census Health and Environment Cohort (CanCHEC). Methods: In this long-term study of 2.6 million people, based on completion of the long-form Census in 1991 and followed up until 2011, we used annual residential addresses to determine the total length of local roads within 200 m of centroid of postal codes, and the subject's distance to primary highways. The association between exposure to traffic and cause-specific mortality was estimated using Cox proportional hazards models, adjusting for individual covariates and contextual factors, including census division-level proportion in high school, the percentage of recent immigrants, and neighborhood income. We performed sensitivity analyses, including adjustment for exposure to PM<sub>2.5</sub>, restricted to subjects in core urban areas, and spatial variation by climatic zone. Results The hazard ratio (HR) for all non-accidental mortality associated with an interquartile increase in length of local roads was 1.05 (95% CI 1.04, 1.05); and for an interquartile range increase in proximity to primary highways, 1.03 (95% CI 1.02, 1.04). However, HRs by traffic quartile increased with increasing lengths of local roads, or closer proximity to primary highways, for all mortality causes. The associations were stronger in subject residing in urban core areas, attenuated by adjustment for PM<sub>2.5</sub>, and HRs showed limited spatial variation by climatic zone. Conclusion: In the CanCHEC cohort, exposure to greater road density and proximity to major traffic roads were associated with increased mortality risk from cerebrovascular and cardiovascular disease, ischemic heart disease, COPD, respiratory disease, lung cancer, and with unclear results for diabetes.

**P03.0970. Air Pollutants and Incidence of All-Cause, Lung, and Bladder Cancer in the Gazel Cohort (1989-2014)**

Emeline Lequy-Flahault

*Bénédicte Jacquemin<sup>2</sup>, Emeline Lequy-Flahault<sup>1</sup>, Kees de Hoogh<sup>4</sup>, Danielle M. Vienneau<sup>4</sup>, Jack Siemiatycki<sup>3</sup>, Sergey Zhivin<sup>1</sup>, Marie Zins<sup>1</sup>, Marcel Goldberg<sup>1</sup>*

4. Swiss Tropical and Public Health Institute, Basel, Switzerland.

**Abstract:** Background/Aim While air pollutants - fine particulate matter (PM<sub>2.5</sub>), nitrogen dioxide (NO<sub>2</sub>), ozone (O<sub>3</sub>) and black carbon (BC) - are associated with mortality, their association with cancer incidence remains unclear. We aimed to analyze the relationships between these pollutants and the incidence of all-cause, lung and bladder cancer in the French general population-based cohort Gazel. Methods Land use regression models with back-extrapolation were used to assess the long-term exposure to PM<sub>2.5</sub>, NO<sub>2</sub>, O<sub>3</sub> and BC at home addresses of 19,530 participants, as the average exposure between enrolment and cancer incidence or censoring, whichever came first, with a 10-year lag to account for the time between initial exposure and the development of cancer. Follow-up was from 1989 to 2014. We used Cox models to derive hazard ratios (HR) for an interquartile range (IQR) increase of single pollutant exposure, adjusted for lifestyle and socioeconomic individual covariables at baseline including gender and occupational exposures, and with age as the underlying time scale. Results We found significant associations between PM<sub>2.5</sub> (IQR 7 µg/m<sup>3</sup>) and incident all-cause and lung cancer with respective HR of 1.15 (CI 1.10-1.21) and 2.08 (1.76-2.45); between NO<sub>2</sub> (IQR 21 µg/m<sup>3</sup>) and all-cause and lung cancer with respective HR of 1.05 (1.01-1.10) and 1.32 (1.11-1.57); between BC (IQR 1 µg/m<sup>3</sup>) and all-cause and lung cancer with respective HR of 1.05 (1.01-1.09) and 1.43 (1.23-1.66). No significant association was found between O<sub>3</sub> and incident cancers, nor between any pollutant and bladder cancer. Conclusions PM<sub>2.5</sub>, NO<sub>2</sub> and BC are associated with incidence of all-cause and specifically lung cancer in a general population-based cohort.

### **P03.0980. Elevated Particulate Matter and Noise Exposure for Spectators at Outdoor Motorsport Events**

Ben Greenfield

Abstract: Since the first recorded steam carriage race in Manchester England, in 1867, motorsport racing has been a globally popular and commercially successful leisure activity. Enthusiasts enjoy a wide range of events, including Formula, stock car, motocross, drag, and many other styles. Despite the many environmental health hazards present at racing events, there have been no published exposure assessment studies for event spectators. To address this knowledge gap, we conducted noise and particulate matter exposure assessment at a series of auto and motocross racing events. Sampling was conducted from May to October, 2017 in designated spectator seating areas at two dirt auto racing tracks, a paved auto racing track, and a dirt motocross track in the St. Louis metro-east region, Illinois, USA, and in Sedalia, Missouri, USA. Using a TSI Instruments SidePak AM520 personal aerosol monitor, arithmetic mean PM<sub>2.5</sub> concentration ranged from 51 to 86  $\mu\text{g m}^{-3}$  across eight race events. Using a Digi-Sense portable sound meter, arithmetic mean noise levels ranged from 75 to 92 dB, and maximum noise levels ranged from 85 to 105 dB across nine race events. PM<sub>2.5</sub> at individual race events was combined with 24 hr average concentration data from Illinois EPA's Granite City, IL ambient air monitoring sites to obtain time weighted average estimated 24 hour PM<sub>2.5</sub> exposure for race spectators. Based on these calculations, 24 hour PM<sub>2.5</sub> for race spectators would be 1.8 to 3.5 times local background exposure. These values corresponded to EPA Air Quality Index levels of 63 to 92, falling in the Moderate category, which presents potential respiratory symptoms to highly sensitive individuals. Planned future data collection includes gravimetric sampling, and particle composition analyses. Our results suggest that despite the short duration of these activities, there are possible respiratory hazards from airborne particulate matter exposure for spectators with preexisting vulnerability.

### **P03.0990. Change in Fine Particle-Related Premature Deaths among Vulnerable and Susceptible Population Subgroups in the U.S. between 1980 and 2010**

Neal Fann

*Neal Fann<sup>1</sup>, Evan Coffman<sup>1</sup>, Sun-Young Kim<sup>2</sup>, Anjum Hajat<sup>3</sup>*

*3. University of Washington, Seattle, WA, United States.*

Abstract: As levels of air pollution such as fine particles (PM<sub>2.5</sub>) have declined over time, so has the burden to public health. A large body of literature has examined the change over time in the recent and historical public health burden of common air pollutants including PM<sub>2.5</sub> in the United States (US). These studies have reported aggregate cases of deaths and illnesses attributed to PM<sub>2.5</sub>, but less is known about how changes in air pollution levels over time have impacted vulnerable and susceptible population subgroups. In this analysis, we draw upon the results of an air quality prediction model that estimates historical changes PM<sub>2.5</sub> between 1980 and 2010 across all counties in the contiguous U.S. For the year 1980, we define groups of vulnerable and susceptible populations according to attributes including county-level educational attainment, income, urbanicity, and all-cause death rate. Using a health impact function, we quantify PM<sub>2.5</sub>-attributable premature deaths for 1980 and 2010 among the overall U.S. population as well as these subgroups. Then we used the Atkinson Index to explore the inequality in the absolute level and change in PM<sub>2.5</sub> mortality among and between subgroups. Between 1980 and 2010, total PM<sub>2.5</sub> mortality risk declined for all groups. Risk inequality, as measured by the Atkinson Index and Gini coefficient, fell across all population groups and the risk experienced among each vulnerable and susceptible group becomes more equitably distributed. These results suggest that falling ambient PM<sub>2.5</sub> concentrations over a 30-year period yield significant benefits among populations most susceptible and vulnerable to poor air quality. Furthermore, our results imply that policy regulations such as the Clean Air Act are effective at reducing health disparities.

### **P03.1000. Air Pollution Mortality Risk and Socioeconomic Status in the Canadian Census Health and Environment Cohort**

Amanda Pappin

- 3. Natural Sciences and Engineering Research Council of Canada, Ottawa, ON, Canada.*
- 4. Population Studies Division, Health Canada, Ottawa, ON, Canada.*

**Abstract:** Background: Social inequalities in air pollution exposure and associated health burdens have been documented in the literature for decades. Materially and socially disadvantaged groups tend to have higher exposures to air pollution and may be more susceptible due to co-occurrence of other stressors, barriers in access to health care, etc. Better characterization of air pollution impacts by socioeconomic status (SES) is needed to inform strategies for mitigating risks in vulnerable populations. Methods: We examine the relationships between SES, fine particulate matter (PM<sub>2.5</sub>) exposure, and risk of mortality in a population-based Canadian cohort, the Canadian Census Health and Environment Cohort (CanCHEC). We run Cox proportional hazards models over a 10.6-year period and using 1 km resolution PM<sub>2.5</sub> estimates to evaluate whether individual level SES modifies the association between PM<sub>2.5</sub> and non-accidental mortality. Our analyses are adjusted for income adequacy, education, ethnicity, marital status, and neighborhood level SES. We will extend our final analysis to include nitrogen dioxide (NO<sub>2</sub>) and ozone. Results: Our preliminary results indicate that PM<sub>2.5</sub> exposure levels are highest among visible minorities, persons with low income adequacy, and persons who are university educated. We further find that educational attainment, income adequacy, marital status, and employment status significantly modify the association between PM<sub>2.5</sub> and mortality risk. Associations between PM<sub>2.5</sub> and mortality are stronger among: persons without a university education, persons with low income adequacy, and visible minorities. These trends are robust to adjustment for other SES indicators. Conclusions: Our findings indicate that air pollution risks vary significantly by SES, even in a population with universal access to health care, and that air pollution reduction strategies that prioritize environmental equity can benefit from more refined risk estimates for affected populations.

### **P03.1010. Chronic PM2.5 Exposure and Lipids/Lipoproteins among Midlife Women**

Xiangmei Wu

*Xiangmei Wu<sup>2</sup>, Rachel Broadwin<sup>2</sup>, Rupa Basu<sup>2</sup>, Brian Malig<sup>2</sup>, Keita Ebisu<sup>2</sup>, Ellen Gold<sup>1</sup>, Lihong Qi<sup>1</sup>, Carol Derby<sup>3</sup>, SungKyun Park<sup>4</sup>, Shelley Green<sup>2</sup>*

Abstract: Fine particles (PM2.5) are known to increase risks of cardiovascular diseases, but very few studies have examined impact of long-term PM2.5 exposure on plasma lipid. In this study, we examined the association between PM2.5 exposure and lipid/lipoprotein among 2289 midlife women from six sites across U.S. between 1999 and 2005 (average 49±3 years old at the first visit included), and explored potential vulnerable subgroups. PM2.5 data were obtained from the U.S. Environmental Protection Agency monitoring network. The average prior one-year exposure was calculated and assigned to each woman based on proximity of the monitors to her residential address. Mixed effects models were used to account for repeated measures for each woman, adjusted for site, race/ethnicity, education, and time-varying variables including age at the visit, visit number, menopausal status, body mass index (BMI), smoking status, alcohol use in the past 24 hours, hormone use, and non-work activity level. The changes in lipids/lipoproteins presented different patterns by dyslipidemia status, menopausal status, and BMI categories. With increased PM2.5 exposure, increased atherogenic lipoproteins, such as, Apolipoprotein (Apo) B and lipoprotein(a), were observed in women without dyslipidemia and women with BMI less than 25, e.g., 5.0% (95%th CIs: 0.8%, 9.4%) and 6.1% (1.1%, 11.3%) increases in ApoB in these two groups, respectively, per 10 µg/m<sup>3</sup> increase of one-year average PM2.5 exposure. Reduced protective lipoproteins, including ApoA1 and lipoprotein A1, were observed in women with dyslipidemia and overweight (25≤BMI<30) and obese (BMI≥30) women. Both trends were observed in peri-menopausal women (had a period within the past 11 months but became irregular). These results suggested that chronic PM2.5 exposure was adversely associated with lipid levels through different mechanisms in midlife women, and all lead to increased cardiovascular risks.

### **P03.1020. Association between Changes in Air Pollution Levels and Airway Inflammation in Healthy Young Adults**

Bin Han

*Bin Han<sup>1</sup>, Liwen Zhang<sup>2</sup>, Jia Xu<sup>3</sup>, Wen Yang<sup>1</sup>, Xinhua Wang<sup>1</sup>, Chunmei Geng<sup>1</sup>, Nan Zhang<sup>1</sup>, Ruojie Zhao<sup>2</sup>, Zhipeng Bai<sup>1</sup>*

*2. Department of occupational and environmental health, Tianjin Medical University, Tianjin, Tianjin, China.*

*3. Department of occupational and environmental health sciences, University of Washington, Seattle, WA, United States.*

**Abstract:** Background: The associations between short-term exposure to fine particulate matter and airway inflammation factors are still not well understood in healthy young adults. Objectives: To determine whether FeNO (Fractional exhaled nitric oxide, the maker of airway inflammation) is sensitive to changes in ambient PM<sub>2.5</sub> concentration. Methods: We measured FeNO data in 67 healthy young college students every season during last three years (Nov. 2014 to Jan 2018), and collected urban PM<sub>2.5</sub> daily concentration data through our study periods. Linear mixed-effect models was used to evaluate the change in FeNO measurement during different season and year under different PM<sub>2.5</sub> pollution level. Results: PM<sub>2.5</sub> concentration showed evident seasonal variation during past three years, except the winter in 2018. Because of strict control on air pollution in studying area, low concentration of PM<sub>2.5</sub> was observed in the winter. Correspondingly, the mean value of FeNO measurements in this winter was significantly lower than that in previous seasons, indicating low PM<sub>2.5</sub> concentrations would lead to the attenuation of the airway inflammation. Model results showed that interquartile range increase in PM<sub>2.5</sub> concentrations was associated with increases in the FeNO measurement (38%, 95%CI: -4%-81%). Conclusion: PM<sub>2.5</sub> exposures are associated with increased level of airway inflammation.

### **P03.1030. Personal Exposure to PM2.5, Black Carbon and Carbon Monoxide and Their Effects on Atherosclerosis: A Cross Sectional Assessment in Bangladesh**

**Abstract:** About 40% of the world's population are exposed to hazardous particles from biomass fuel use at households. Effects of such exposures on preclinical markers of cardiovascular diseases (CVD) are practically challenging to measure and mostly unexplored in low- and middle-income countries. GEOHealth study is examining the effect of individual level exposures to PM 2.5, black carbon (BC) and carbon monoxide (CO) on atherosclerosis among 600 biomass fuel users in rural Bangladesh. We are measuring PM 2.5 by gravimetric method using personal air samplers (RTI MicroPEMT). BC is being determined by reflectance measurement using an EEL-type smoke stain Reflectometer. CO is measured by Lasker EL-USB CO data logger. We assessed Carotid intima thickness (cIMT), a marker of atherosclerosis, using the SonoSite MicroMaxx ultrasound machine equipped with a L38e/10-5 MHz transducer. We are using the mean of the near and far walls of the maximum common carotid artery (CCA) IMT from both sides of the neck as the outcome variable. Structured questionnaire is used to record important co-variables. The primary analysis was conducted among 100 women (mean age 40±8 years), who has been using biomass fuel in traditional stoves for 20±9 years. They were all non-smoker with low (<5 µg/L) exposure to water arsenic and not known to have any CVD. Average 48 hour exposure to PM2.5, BC and CO was 124µg/m<sup>3</sup> (SD 108), 4.8 µg/m<sup>3</sup> (SD 2.1) and 1.2 ppm (SD 0.9) respectively. Mean cIMT is 740.9µm (SD 78). We will construct a multiple linear regression model and strength of association adjusted for important co-variables will be reported. We plan to complete data analysis on 200 samples by June 2018 and expect to present the finding at the ISEE meeting. Findings will help establish effects of HAP on atherosclerosis providing insights into magnitude, underlying mechanism and prevention strategies of the problem.

### **P03.1040. The Association of Premature Ovarian Failure (POF) and Air Pollution in Korea Based on Health Insurance Cohort Data**

Eunil Lee

*Eunil Lee<sup>1</sup>, Yun Jeong Kim<sup>1</sup>, Yuri Jeong<sup>1</sup>*

*1. Preventive Medicine, Korea University, Seoul, Korea (the Republic of).*

Abstract: [Background] Recently prevalence of premature ovarian failure (POF) continues to increase in Korea and we found that Kwanwon province showed the highest POF prevalence among sixteen provinces. The purpose of this study is to find the hot spot areas among 234 administrative districts with significant variables associated with POF prevalence. [Methods] We used the customized cohort DB from 2004 to 2013 provided by National Health Insurance Corporation. The total number of women in DB was 556,467 and the number of POF patients was 4,870. We estimated the POF prevalence in each districts and hot spot analysis was done to find the POF clusters. And we also evaluated the association between POF prevalence and environmental factors including air pollution data from air monitoring data with drinking, smoking, obesity, stress, education, income, number of visits to clinics and hospitals from National Health Examination Survey data. [Results] Hot spot analysis showed highest areas including five districts in Kangwon and Gyeongsangbukdo provinces. And there were lowest areas, cold spot, including nine districts in Chungchung provinces. And only air pollution data including NO<sub>2</sub>, O<sub>3</sub>, PM<sub>10</sub> showed significantly associated with POF prevalence. We did the same analysis after excluding Kangwon province for reducing possibility of genetic effects of regional residents. OLS regression showed that NO<sub>2</sub> and O<sub>3</sub> were significantly associated with POF prevalence and there was no hot spot area after excluding Kangwon province. [Conclusion] The further study is needed to evaluate the association between POF prevalence and air pollution with distribution of POF related genes among residents in hot spot areas. [Acknowledgment] This work was supported by the Korea Ministry of Environment (MOE) as The Environmental Health Action Program (2016001360007).

### **P03.1060. Impact of Air Pollution on the Newborn Genome**

Radim Sram

*Radim J. Sram*<sup>1</sup>

*1. Genetic Toxicology and Nanotoxicology, Institute of Experimental Medicine CAS, Prague 4, Czechia.*

**Abstract:** Background. The Northern Moravia Region is the most polluted region in the Czech Republic by particulate matter (PM<sub>2.5</sub>) and carcinogenic polycyclic aromatic hydrocarbons (c-PAHs) as benzo[a]pyrene (B[a]P) by heavy industry, traffic and local heating. This specific situation was used to study the impact of air pollution to newborns in the exposed district Karvina (K) and control district Ceske Budejovice (CB). Methods. Milk, blood and urine from 100 mothers and cord blood and urine from 100 newborns were collected in winter and summer in each district. Concentrations of c-PAHs were determined from HiVol samples of PM<sub>2.5</sub>. As biomarkers were determined DNA adducts by 32P-postlabeling, oxidative damage by 8-oxodG adducts and 15-2Ft-isoprostane, ETS by cotinine, gene expression profiles. PAHs were determined in breast milk and diet, monohydroxylated PAHs (OH-PAHs) in urine. Results. During the sampling, concentrations of PM<sub>2.5</sub> in summer were 21.54±11.78 mg/m<sup>3</sup> in K, 12.14±7.23 mg/m<sup>3</sup> in CB, in winter 55.35±38.74 mg/m<sup>3</sup> and 26.39±16.85 mg/m<sup>3</sup>, respectively. Concentrations of B[a]P in summer were 1.31±1.26 ng/m<sup>3</sup> in K, 0.44±0.63 ng/m<sup>3</sup> in CB, in winter 5.15±5.47 ng/m<sup>3</sup> and 1.43±1.37 ng/m<sup>3</sup>, respectively. Total DNA adducts in the cord blood in winter were 2.76±1.11 in K vs. 2.32±0.90 adducts/108 in CB (p<0.001), B[a]P-like DNA adducts were 0.72±0.28 in K vs. 0.62±0.28 adducts/108 in CB (p<0.001). 8-oxodG adducts (nmol/mmol creat.) in the urine of newborns in winter were 5.66±12.90 in K vs. 4.23±1.51 in CB (p<0.001). Very low concentrations of PAHs were measured in diet and breast milk samples. The amount of OH-PAHs in newborns urine from K in the winter season was 3.3 times higher when compared with less polluted locality of CB. Conclusions. Exposure to B[a]P represents the most significant risk of air pollution in the Czech Republic as more than 55% of population is exposed to > 1 ng/m<sup>3</sup>/year. Acknowledgement: Supported by the Grant Agency of the Czech Republic 301/13/458S.

**P03.1070. Preliminary Study to Determine the Association between Maternal Exposure to Fine Particulate Matter (PM2.5) and Adverse Pregnancy Outcomes in Lima, Peru**

Julio Rubio

*Julio Rubio<sup>1</sup>, Vilma Tapia<sup>1</sup>, Bertha Vasquez<sup>1</sup>, Kyle Steenland<sup>2</sup>, Gustavo F. Gonzales<sup>1</sup>*

*1. Universidad Peruana Cayetano Heredia, Lim, Lima, Peru.*

*2. EMORY University, Atlanta, GA, United States.*

**Abstract:** Environmental exposure to fine particulate matter (PM) is associated with increased risks for respiratory and cardiovascular diseases as well as some kinds of cancer and pregnancy adverse outcomes. Among others, Lima, a mega city located in Peru, has been considered one of the most contaminated cities in Latin America with mean annual concentrations of PM<sub>2.5</sub> ranging from 35 to 16 µg/m<sup>3</sup> (mean value: 26 µg/m<sup>3</sup>). Besides that, there are no studies related to the effect of outdoor PM air pollution on pregnancy outcomes in Lima, Peru. The aim of this preliminary study is to determine the association between maternal exposure to PM<sub>2.5</sub> on pregnancy outcomes in a hospital-based linkage study in the metropolitan area of Lima. This study analyzes the data corresponding to the period between January 2007 and December 2009. Newborn data were obtained through the Perinatal Information System (SIP 2000 in Spanish) from two public hospitals in Lima, Peru. Preterm birth (PTB), small for gestational age (SGA) and birth weight (BW) were considered as pregnancy outcomes. Also, records of PM<sub>2.5</sub> during this same period were recorded. Linear and logistic regression analyses were used to predict adverse pregnancy outcomes associated with PM<sub>2.5</sub> exposure. Data included 4,173 births. Of the three pregnancy outcomes, the exposure to higher concentrations of PM<sub>2.5</sub> (3rd quartile) were associated with an elevated risk of preterm birth in the 1st trimester (OR 1.62, CI95% 1.06 - 2.49), 2nd trimester (OR 1.71, CI95% 1.13 - 2.58), and 3rd trimester (OR=1.87, CI95% 1.27 - 2.76). To sum up, maternal exposure to PM<sub>2.5</sub> during pregnancy increase risks for preterm births. Future studies are being carried out to expand the years of exposure according to the use of time-series analysis and the collection of current newborn data.

**Abstract:** Introduction: There is a growing body of literature that supports an association between prenatal air pollution exposure and increased risk of childhood obesity. However, relationships between prenatal air pollution and growth among preschool age children, a developmental stage that predates most child obesity onset, have not been well studied. Methods: In a pre-birth cohort of 495 children in Mexico City we measured body fat percentage at 7 years of age by bioimpedance. Our cohort was 53% male with mean body fat percentage of 23.3% (SD = 7.6); among females the mean body fat percentage was 26% (SD = 8.4). Average ambient fine particulate matter (PM2.5) exposure was estimated at the home address during pregnancy using a 1km resolution hybrid satellite land use regression model. Findings: We found that body fat percentage at 7 years of age was negatively associated with average PM2.5 exposure during pregnancy using a multivariable regression model ( $b = -0.074$ , 95% CI: -0.677, -0.048), when adjusted for child age, socioeconomic status, sex, and maternal pre-pregnancy weight (Adj R<sup>2</sup> = 0.095). Average first trimester PM2.5 exposure was similarly negatively associated with body fat percentage at 7 years, PM2.5 during the second or third trimesters, or during the first year postpartum, was not associated with body fat at either timepoint. Conclusion: Although the magnitude of this finding may be small to be clinically relevant; further work including distributed lag modeling and longitudinal models of phenotypic trajectories may reveal specific exposure windows that are important. Our finding may also suggest that lower body fat in the preschool age children who were exposed to higher prenatal PM2.5 reflects an altered growth trajectory with consequences for later obesity in puberty. We will follow the cohort into puberty and continue to examine these associations.

**P03.1090. Effect Modification of the Association between Ambient Air Pollution Exposure and Fecundity by Infertility Type among Women Undergoing In Vitro Fertilization**

Sabah Quraishi

Abstract: Mounting evidence indicates air pollution (AP) is adversely associated with birth outcomes, but few studies characterize the association with fecundity. We evaluated the association between long-term ambient AP and outcomes in women undergoing in vitro fertilization (IVF). This study takes advantage the known date of pregnancy attempt in IVF and investigates if type of infertility acts as a modifier of the AP-live birth association. Clinical data on women initiating their 1st autologous IVF cycle in 2012-13 were obtained from four US clinics. Annual average exposure prior to IVF start were estimated at residential address using a national spatial model that used land use regression and universal kriging to estimate particulate matter  $\leq 2.5$  (PM<sub>2.5</sub>), PM<sub>10</sub>, and nitrogen dioxide (NO<sub>2</sub>). Modified Poisson regression was used to measure the association between AP and fertilization, pregnancy, pregnancy loss, and live birth. Additive effect modification (EM) of AP and live birth by type of infertility (diminished ovarian reserve (DOR), male, ovulation, tubal) was evaluated using relative excess risk due to interaction (RERI). Higher exposure to PM<sub>2.5</sub>, by IQR-unit, was associated with a lower likelihood of live birth (RR:0.96, 95%CI:0.90-1.02) and higher likelihood of pregnancy loss (RR:1.09, 95%CI: 0.93-1.26). Results were similar for PM<sub>10</sub> and NO<sub>2</sub>. RERI analysis resulted in negative values, indicating lower likelihood of live birth with EM on an additive scale comparing high AP and DOR (PM<sub>2.5</sub>,PM<sub>10</sub>,NO<sub>2</sub>, all p<0.01) or high AP and male infertility (PM<sub>2.5</sub>,PM<sub>10</sub>,NO<sub>2</sub>, all p<0.001) with low AP and no DOR or male factor, respectively. Despite suggestive but uncertain findings for the association between AP and IVF outcomes, we found an indication of synergistic effects of AP and DOR or male infertility on the likelihood of live birth in women undergoing IVF. This suggests that DOR and male infertility should be further explored in future research evaluating effect of AP on fecundity.

### **P03.1100. Association between Ambient Air Pollutants and Preterm Birth in Ningbo, China: A Time-Series Study**

Zhe-Bin Yu

*Zhe-Bin Yu<sup>1</sup>, Wen-Yuan Liu<sup>3</sup>, Hai-Yan Qiu<sup>3</sup>, Die Li<sup>1</sup>, Xue-Yu Chen<sup>1</sup>, Jian-bing Wang<sup>2</sup>, Kun Chen<sup>2</sup>*

- 1. Zhejiang University, Hangzhou, Zhejiang, China.*
- 2. Research Center for Air Pollution and Health, Zhejiang University, Hangzhou, China.*
- 3. Ningbo Women and Children's Hospital, Ningbo, China.*

**Abstract:** Background: Exposure to air pollutants has been related to preterm birth, yet evidence for PM<sub>2.5</sub>, O<sub>3</sub> and CO is relatively limited in China. This study aimed to investigate the short-term effect of exposure to air pollutants on preterm birth risk during 2014-2016 in Ningbo, China. Methods: We conducted a time-series study to evaluate associations between daily preterm birth and major air pollutants (PM<sub>2.5</sub>, PM<sub>10</sub>, SO<sub>2</sub>, NO<sub>2</sub>, O<sub>3</sub> and CO) in Ningbo during a three-year period (2014-2016). The relationship between preterm birth and air pollution was analyzed by General Additive Model extend Poisson regression to control for time-trends, meteorological factors and day of the week(DOW). We also conducted subgroup analysis by season and age. Results: In this study, a total of 37,389 birth occurred between 2014 and 2016 from the Electronic Medical Records System of Ningbo Women and Children's Hospital and among which 5428 were defined as preterm birth. The single pollutant model suggested that lag effect of PM<sub>2.5</sub>, PM<sub>10</sub>, SO<sub>2</sub>, NO<sub>2</sub> reached a peak at day 3 before delivery, and no significant relationships were found for O<sub>3</sub>, CO and preterm birth. An increase of 10 µg/m<sup>3</sup> of air pollutants corresponded to excess risks (ERs) of 2.05(95%CI: 0.98~3.14) for PM<sub>2.5</sub>, 1.30(95%CI: 0.46~2.15) for PM<sub>10</sub>, 9.2(95%CI: 5.76~12.74) for SO<sub>2</sub>, 4.19(95%CI: 2.19~6.24) for NO<sub>2</sub>, -0.23(95%CI: -1.21~0.77) for O<sub>3</sub>, and 0.08(95%CI: 0.00~0.16) for CO. The effect of air pollutant remained significant when we restricted our analyses in pregnant women aged between 18 and 35 years . Conclusions: This study indicates that short-term exposure to air pollutants such as PM<sub>2.5</sub>, PM<sub>10</sub>, SO<sub>2</sub>, NO<sub>2</sub> are positively associated with risk of preterm births in Ningbo, China.

### **P03.1110. Critical Windows of Ambient NO<sub>2</sub> Exposure on Fetal Growth at Late Pregnancy**

Carmen Iñiguez

*Carmen Iñiguez<sup>1</sup>, Kristina W. Whitworth<sup>2</sup>, Ferran Ballester<sup>3</sup>, Olga Costa<sup>4</sup>, Marisa Estarlich<sup>3</sup>, Mario Murcia<sup>5</sup>, Ana Esplugues<sup>3</sup>, Monica Guxens<sup>6</sup>*

- 4. Fisabio, València, Spain.*
- 5. CIBERESP, Madrid, Spain.*
- 6. ISGLOBAL, Barcelona, Spain.*

**Abstract:** Objective Our aim was to assess critical windows of weekly exposure to ambient NO<sub>2</sub> on ultrasound-measured fetal growth in a cohort of pregnant women from Valencia, Spain, (INMA project). Methods Ultrasounds were performed around 12, 20 and 34 weeks of pregnancy for all women (n=787) and measurements of biparietal diameter (BPD), abdominal circumference (AC) and femur length (FL) were used to estimate fetal weight (EFW). A longitudinal growth curve for each parameter was fit with linear mixed models, adjusted for maternal height, weight, age, parity, and ethnicity. Growth curves were used to calculate SD-scores at week 34, which served as outcomes in this analysis. Weekly residential NO<sub>2</sub> exposure was estimated by temporally adjusted Land-Use Regression based on ambient NO<sub>2</sub> concentrations for 93 sampling points covering the study area and the existing ambient monitoring network of the city. Distributed lag non linear models, adjusted for socioeconomic and lifestyle variables, were used to explore critical weeks of exposure. Effect estimates were summarized as percent change (%CH) per 10 µg/m<sup>3</sup> increase in NO<sub>2</sub>. Results NO<sub>2</sub> exposure in gestational weeks 4-8 was inversely associated with BPD, with peak magnitude at week 5 (%CH=-0.87, 95%CI=-1.49, -0.25). NO<sub>2</sub> exposure was inversely associated with AC in weeks 16-21 and with EFW in weeks 18-21. In both cases the association peaked at week 19 [AC %CH=-0.87 (-1.37, -0.25) and EFW %CH=-0.65 (-1.20, -0.09)]. NO<sub>2</sub> exposure was not associated with FL. Discussion This study indicates that early pregnancy may be a critical window of exposure to outdoor NO<sub>2</sub> for head size and mid pregnancy may be for weight. Results were in line with a previous study using the same data, but the present method allowed for an agnostic and refined assessment of potential windows of susceptibility without using a priori definitions (e.g. trimesters). Funding: ISCIII-FEDER ( PI13/1944, MS11/0178, MSII16/00051, MS16/00128) and Alicia Koplowitz Foundation 2017.

### **P03.1120. Air Pollution Fluctuations and Adverse Pregnancy Outcomes in a Community of Southwest Bogota during 2016**

Rodrigo Sarmiento

*Yuliet Landinez Romero<sup>1</sup>, Angie Gonzalez-Cortes<sup>1</sup>, Rodrigo Sarmiento<sup>1</sup>*

*1. Programa de Medicina, Universidad de Ciencias Aplicadas y Ambientales UDCA, Bogota D,c, Colombia.*

**Abstract:** Background: Air pollution and pregnancy outcomes have been widely described, however less is known about the temporal fluctuations and their health impact. Southwest communities in Bogota are the most vulnerable population to air pollution having a PM10 annual average of nearly 80 mcg/m<sup>3</sup>. Aim of the study was to identify potential adverse effects during advanced pregnancy according to the temporal patterns of air pollution in a deprived community in Bogota. Methods: A cross sectional study of women from 28 to 42 weeks of pregnancy that assisted at a second level hospital in Bogota's Southwest during 2016 was carried out. The sample included 126 women that were divided in two groups: A group of high levels of exposure that had their pregnancy during the dry season and the other one that had their pregnancy during the rainy season. PM10 was used as exposure variable and the outcomes were birth weight, systolic and diastolic blood pressure. PM10 level was adjusted by rainfall and temperature. Statistical analysis included t-test for independent samples and linear regression. Results: There were differences between mean PM10 during dry season (89 mcg/m<sup>3</sup>) and mean PM10 during the rainy season (66 mcg/m<sup>3</sup>) (p<0,05). Birth weight was significantly less (Mean difference=-388,1 gr, UI 95%: -507 a -268) in the group of high levels of exposure (2903kg ± 358,4) compared to the other group (3291kg±288,1). Such difference persisted during lineal regression after adjusting for temperature and cumulative rainfall (Beta=0.59 p<0.05). Other outcomes that were assessed did not show significant differences according to the levels of exposure. Conclusions: A temporal pattern of air pollution exposure and birth weight was observed in a polluted area of Bogota. Such findings have implications in maternal and child health and outline the importance of including these temporal variations on air pollution surveillance and control initiatives.

### **P03.1130. Associations of Industrial Air Pollutant Mixtures with Preterm Birth and Small for Gestational Age in Alberta, Canada**

Jesus Serrano-Lomelin

*Jesus Serrano-Lomelin<sup>1</sup>, Charlene Nielsen<sup>2</sup>, Paul Villeneuve<sup>3</sup>, Alvaro Osornio Vargas<sup>2</sup>*

- 2. Pediatrics, University of Alberta , Edmonton, AB, Canada.*
- 3. Health Sciences, Carleton University, Ottawa, ON, Canada.*

**Abstract:** Introduction: Effects of mixtures of chemicals released to the air by industrial facilities on pregnancy outcomes have been scarcely studied. We conducted a retrospective population-based cohort study to estimate associations of spontaneous preterm birth (sPTB), induced preterm birth (IPTB) and small for gestational age (SGA) with industrial air pollutant mixtures in Alberta, Canada (2006-2012). Methods: We used data from all singletons live births (n=330,957) including maternal data on 21 related risk factors. From the Canadian National Pollutant Released Inventory, we extracted 130 chemicals released into the air by 6,279 industrial facilities. We grouped all chemicals into ten broad classes including gases (e.g., CO), particulate matter (PM), Volatile Organic Compounds (VOCs), Metals, Other-inorganics, and Other-organics. We profiled the mixtures using a novel approach based on the proportional content of the ten chemical classes in the total amounts released by each facility using cluster analysis. Proximity to the facilities emitting mixtures (10-km) from the maternal postal codes at delivery was used as a proxy of exposure. Associations of the mixtures with sPTB, IPTB and SGA were assessed by logistic regression adjusting for relevant maternal risk factors and an area-level socioeconomic status. Results: We profiled eight broad groups of mixtures. Heterogeneous mixtures (including gases, PM and different proportional participation of the other chemical classes) were common (47% of the total emissions) and increased the odds of sPTB by 36% (OR=1.36; CI:1.30-1.63). Scarce mixtures with a high content (>60%) of VOCs increased the odds of SGA by 37% (OR=1.37; CI:1.11-1.69). Mixtures with a high proportion of Metals-, Other-organics- and Other-inorganics increased the odds of IPTB by 17% (OR=1.17; CI:1.05-1.30), 17% (OR=1.17; CI:1.06-1.28) and 24% (OR=1.24; CI:1.09-1.41) respectively. Conclusion: Mixtures showed differential associations with sPTB, IPTB, and SGA.

**P03.1140. Prenatal, Early-Life and Lifetime Exposure to Air Pollution and Childhood Lung Function and Asthma: The Avon Longitudinal Study of Parents and Children (ALSPAC) Cohort Study**

Yutong Cai

Yutong Cai<sup>1</sup>, Anna Hansell<sup>1</sup>, Raquel Granel<sup>2</sup>, Marta Blangiardo<sup>1</sup>, Daniela Fecht<sup>1</sup>, John Gulliver<sup>1</sup>, John Henderson<sup>2</sup>, Paul Elliott<sup>1</sup>

1. MRC-PHE Centre for Environment and Health, Department of Epidemiology and Biostatistics, Imperial College London, London, United Kingdom.

2. Population Health Sciences, Bristol Medical School, University of Bristol, Bristol, United Kingdom.

**Abstract:** Background: Only a few studies have investigated early-life air pollution exposures on childhood lung function and asthma, with inconsistent results. We examined associations of exposure to air pollution during pregnancy, infancy and lifetime periods with lung function and current asthma in the Avon Longitudinal Study of Parents and Children (ALSPAC) cohort. Methods: Forced expiratory volume in 1 second (FEV1) and Forced vital capacity (FVC) were measured at age 8 years and converted into age-height-gender adjusted z-scores. Current asthma was derived from answers to relevant questionnaire items. Exposures to source-specific particulate matter with a diameter  $\leq 10\mu\text{m}$  (PM10) during each trimester, 0-6 months, 7-12 months (1990-1993) through childhood up to age 8 years (1991-2001) were estimated using a dispersion model, accounting for residential mobility. Linear and logistic regression models were fitted to explore the associations, adjusting for gestational age, damp and mould at home, passive smoking exposure, home ownership, maternal education and smoking during pregnancy. Results: 13,963 study children were included in this analysis. At age 8 years, exposure to interquartile (IQR) higher PM10 ( $0.72\mu\text{g}/\text{m}^3$ ) from road traffic during the first trimester was associated with lower FEV1 ( $-0.05$ , 95%CI:  $-0.08$  to  $-0.02$ ) and FVC ( $-0.05$ , 95%CI:  $-0.08$  to  $-0.02$ ) z-scores. Similar significant associations were also seen with PM10 in the second and third trimester, 0-6 months, 7-12 months and 0-7 years. Associations were stronger among children whose mother had a lower education level or smoked during pregnancy. PM10 from all sources during the third trimester was significantly associated with lower FVC z-scores. Current asthma was not associated with PM10 at any time periods. Conclusion: Preliminary results suggested that exposure to road-traffic PM10 from as early as in the first trimester may result in small but significant reductions in lung function at age 8 years.

### **P03.1150. Assessing the Effects of Residential Mobility on Air Pollution Exposure Misclassification in Longitudinal Birth Cohort Studies**

Andy Boyd

*Daniela Fecht<sup>1</sup>, Kevin Garwood<sup>1</sup>, Oliver Butters<sup>2</sup>, Andy Boyd<sup>2</sup>, John Henderson<sup>2</sup>, Paul Elliott<sup>1</sup>, Anna Hansell<sup>1</sup>, John Gulliver<sup>1</sup>*

*1. UK Small Area Health Statistics Unit, MRC-PHE Centre for Environment and Health, Imperial College London, London, United Kingdom.*

*2. Avon Longitudinal Study of Parents and Children, University of Bristol, Bristol, United Kingdom.*

**Abstract:** To accurately assess environmental exposures in longitudinal cohort studies, a better understanding is needed about the effects of incomplete or inaccurate records of residential mobility on exposure misclassification. We developed an ALgorithm for Generating Address Exposures (ALGAE) that assigns air pollution exposure using residential address histories. We applied ALGAE to address records and historic daily air pollution estimates (particulate matter  $\leq 10 \mu\text{m}$  [PM<sub>10</sub>]) for the Avon Longitudinal Study of Parents and Children (ALSPAC). ALSPAC recruited 14,541 pregnant women between 1990 and 1992 in the South West of England. For each pregnancy, we modelled pregnancy trimester- and first year of life-specific exposure estimates based on PM<sub>10</sub> concentrations at residential address at birth and using reconstructed address histories to account for mobility during pregnancy and first year of life. We were able to assign trimester-specific PM<sub>10</sub> exposures for 12,752 pregnancies and first year of life exposures for 12,252 pregnancies. Average PM<sub>10</sub> exposures were 32.6  $\mu\text{g}/\text{m}^3$  (StDev 3.0  $\mu\text{g}/\text{m}^3$ ) during pregnancy and 31.4  $\mu\text{g}/\text{m}^3$  (StDev 2.6  $\mu\text{g}/\text{m}^3$ ) during first year of life. 6% of women moved address during pregnancy, and 13% moved during first year of life. Exposure differences ranged from -5.3  $\mu\text{g}/\text{m}^3$  to 12.4  $\mu\text{g}/\text{m}^3$  (up to 26%) during pregnancy and -7.22  $\mu\text{g}/\text{m}^3$  to 7.64  $\mu\text{g}/\text{m}^3$  (up to 27%) in first year of life between the exposure assessed using the address at birth compared to the exposure assessed using the complete cleaned address history. Accounting for residential mobility in the exposure assessment of birth cohort studies has the potential to substantially reduce exposure misclassification for some individuals. ALGAE provides an open-source solution to clean addresses stored in the cohort contact database and assigns life-stage specific exposures. Its generic code base means that it is adaptable for other cohort studies.

**P03.1160. Associations between Infant Birth Weight and Seasonal Variations in PM2.5 Exposure during Pregnancy: A Prospective Cohort Study in a Rural Community in China**

Yan Li

Yan Li<sup>1</sup>, Xiaoxiao Song<sup>1</sup>, Xia Xiao<sup>1</sup>, Edmund Seto<sup>2</sup>, Kek-Khee Loo<sup>3</sup>, Jie Wu<sup>1</sup>, Rui Ma<sup>1</sup>, Yan Zhang<sup>4</sup>

1. School of Public Health, Kunming Medical University, Kunming, China.

2. University of Washington, Washington, WA, United States.

3. University of California, Los Angeles, Los Angeles, CA, United States.

4. Yunnan Maternal and Child Health Hospital, Kunming, China.

**Abstract:** Background: Exposure to PM2.5 (fine particulate matter) pollutants in pregnancy has generally been found to be associated with infant low birthweight. In rural China, exposure of pregnant women to PM2.5 from indoor coal or wood-burning heaters, stoves and second-hand smoke is expected to have seasonal variations that may have implications on the birth weight of the offspring. Methods: In a prospective pregnant woman cohort study, 380 pregnant women carried a Portable Particle Monitor to measure 24-hour individual exposure to PM2.5 over a period of 5-7 days at first (T1), second (T2) and third trimester (T3) time points. The questionnaires to women were conducted simultaneously. Newborn were weighted by standard scale at birth. Latent Variable Growth Curve Modeling was used to elucidate the effects of seasonal variation to PM2.5 exposure in the course of pregnancy on the birth weight. Four groups were compared based on the season when the mother was in first trimester. Results: The average PM2.5 exposure throughout pregnancy were 27.2, 26.3, 28.3, and 30.9  $\mu\text{g}/\text{m}^3$  in four groups (their first trimester in Spring, Summer, Autumn and Winter), respectively. Different groups revealed special associational patterns. Intercept factors were -25.8, -51.3, -27.0, and -43.1 for mothers in first semester in Spring, Summer, Autumn and Winter respectively and slope factors were 0.8, -3.7, 8.4, and 8.2, respectively. Mothers in first trimester in Summer had newborns with the lowest birth weight with an increase of one unit of PM2.5 exposure being associated with a decrease in 51.3g in birth weight. Conclusions: PM2.5 exposure was associated with low birth weight across all 4 groups. Mothers who were not exposed to winter had newborns with the highest birth weights. Increased exposure to PM2.5 in the cold seasons may cause the decrease of birth weight and was associated with low birth weight.

### **P03.1170. A Stratified Repeated Measures Design to Examine Acute Effects of Air Pollution on Preterm Birth**

Eric Roberts

*Eric M. Roberts<sup>1</sup>, Paul B. English<sup>2</sup>*

*2. Environmental Health Investigations Branch, California Department of Public Health, Richmond, CA, United States.*

**Abstract:** Background: Epidemiological study of preterm birth typically relies on birth certificate data for which records of gestational age are imprecise, leading to outcome misclassification biases that confound short-term temporal patterns for this outcome. We hypothesize that these biases hinder analysis of acute effects of pollutants using standard time-series approaches and propose an alternative study design as a solution. Methods: We group subjects into strata based on recorded date of last menstrual period and formulate each stratum as a cohort undergoing a repeated measures experiment. To render this design computationally tractable, we make use of t-distributed auxiliary variables and specify a model having two sets of non-nested random intercepts. We demonstrate the approach by estimating a multi-pollutant distributed lag model for births among women living within a 5-km radius of a criteria air pollutant monitor located in downtown Los Angeles during 1998-2012. Results: Compared to those of standard models, our coefficients have larger magnitudes and tend to be monotonically consistent across sequential quartiles of exposure. Both harmful and protective effects are observed, the latter potentially reflecting beneficial delays in delivery arising from clinical interventions directed at women hospitalized for potential preterm delivery. Conclusions: Distributed lag coefficients generated by this method suggest complex, non-random temporal relationships between criteria pollutants and preterm birth risk. While these results fail to demonstrate a simple cause-effect relationship, the method holds promise for advancing our understanding of short-term pollutant effects on this outcome.

### **P03.1180. Benzene Low-Level Personal Exposure Assessed Repeatedly and Fetal Growth: Are Effects Observed in the General Population?**

Remy Slama

*Remy Slama<sup>1</sup>, Marion Ouidir<sup>1</sup>, Sarah Lyon-Caen<sup>1</sup>, Karine Supernant<sup>1</sup>, Nassim Sahki<sup>1</sup>, Joane Quentin<sup>1</sup>, Pascale Hoffmann<sup>6</sup>, Jacques-Noel Canonica<sup>3</sup>, Xavier Morin<sup>4</sup>, Jean-Claude Reynaud<sup>5</sup>, Veronique Equy<sup>6</sup>, Claire Philippiat<sup>1</sup>, Valérie Siroux<sup>1</sup>, Isabelle Pin<sup>2</sup>, Johanna Lepeule<sup>1</sup>*

- 4. Clinique des Cedres, Echirolles, France.*
- 5. Groupe Hospitalier Mutualiste, Grenoble, France.*
- 6. Obstetrical Department, Grenoble University Hospital, Grenoble, France.*

**Abstract:** Context: Benzene is a recognized reprotoxicant but its effects on fetal growth in humans at levels encountered in the general population are poorly known. A study reported decreases in head circumference and possibly birth weight in association with maternal benzene exposure. Aim: To study the possible effect of airborne benzene pregnancy exposure on fetal growth using personal monitoring. Methods: We relied on SEPAGES, a cohort of pregnant women recruited before gestational week 20, who carried personal benzene monitors for two to three 8-day periods. Offspring weight and head circumference were related with benzene levels at each measurement week and averaged over all weeks through adjusted linear regression models. Results: Median (25-75th centiles) benzene 8-day exposure at the first measurement was 1.4 (0.8; 2.2)  $\mu\text{g}/\text{m}^3$ . The correlation of benzene 8-day levels between the first and last measurement periods was 0.25 ( $p < 5.10^{-4}$ ), while for exposure averaged over all measurement periods, benzene levels had a correlation of 0.05 ( $p = 0.4$ ) with nitrogen dioxide and of 0.23 ( $p = 0.001$ ) with PM<sub>2.5</sub> personal exposures. Each unit increase in benzene mean exposure was associated with a mean birth weight change by -18 g (95% confidence interval, CI, -43; 7 g,  $n = 402$ ), while mean head circumference changed by -1.0 mm (95% CI, -1.9; -0.2). Across measurement periods, the strongest association was observed with the first benzene measurement, both for birth weight (change, -30 g; 95% CI, -56; -3) and head circumference (-1.7 mm, 95% CI -2.6; -0.8,  $p < 5.10^{-4}$ ). There was no strong attenuation after adjustment for personal NO<sub>2</sub> or PM<sub>2.5</sub> exposure. Conclusion: This study is the first to characterize possible effects of benzene on birth weight using personal repeated measurements. It provides a confirmation of an association of benzene exposure with head circumference, and suggests that the association is stronger for exposures in the 1st (as opposed to 2nd) half of pregnancy.

**P03.1190. Study on the Relationship between Air Pollution and Insulin Resistance Based on Branched-Chain Amino Acids Analysis**

Jicheng Gong

*Yunxiu Shi<sup>1</sup>, Yiqun Han<sup>3</sup>, Yanwen Wang<sup>4</sup>, Liang Qi<sup>2</sup>, Xi Chen<sup>1</sup>, Wu Chen<sup>1</sup>, Weiju Li<sup>5</sup>, Hongyin Zhang<sup>5</sup>, Jicheng Gong<sup>2</sup>, Tong Zhu<sup>2</sup>*

**Abstract:** Background: Studies showed associations between air pollution exposure and the incidence of diabetes; however, the evidence on the underlying mechanism is limited. Insulin resistance (IR) has been recognized as an important pathogenesis of the metabolic syndrome and type II diabetes. There were studies found that the branched-chain amino acids (BCAAs), including leucine, isoleucine, and valine, could affect the sensitivity of insulin. And it also shown that exposure to air pollution, e.g. ozone, could increase BCAAs' levels in blood. Therefore, we may assume exposure to air pollution has effects on the insulin resistance through the mediation of BCAAs. Method: To examine this hypothesis, we measured BCAAs in serum samples of 120 subjects from an existing panel study (SCOPE). 130 observations from 83 subjects (37 with pre-diabetes, 46 with normal fast glucose level) were included in this preliminary analysis. Serum BCAAs were analyzed by using a UPLC-QQQ-MS. The associations among BCAAs, IR and air pollution exposure were analyzed using Mixed-effects models. Results: The average ( $\pm$  SD) concentrations of leucine, isoleucine and valine in serum were  $148.6 \pm 33.0$   $\mu$ M,  $70.7 \pm 19.1$   $\mu$ M, and  $247.0 \pm 54.9$   $\mu$ M, respectively. We found a significantly higher level of the total BCAAs (combined three BCAAs together) in subjects with pre-diabetes than healthy ones with  $p = 0.004$ . Three individual and the total BCAAs were statistically significantly associated with HOMA-IR which is an indicator of insulin resistance with  $p < 0.042$ . We did not observe statistically significant associations between BCAAs and PM<sub>2.5</sub> or ozone in this preliminary analysis, but valine showed a marginally significant association with ozone ( $p = 0.052$ ). Tentative conclusion: The significant associations observed between BCAAs and insulin resistance from the preliminary analysis suggest BCAAs a potential mediator of insulin resistance. More data are needed to examine the associations between BCAAs and air pollutants.

### **P03.1200. Short-Term Exposure to Ambient Particulate Elements and Epigenome-Wide DNA Methylation in Older Men: The Normative Aging Study**

**Abstract:** Background: Current research suggests that short-term exposure to ambient particulate matter is associated with global and gene-specific DNA methylation (DNAm), but little is known regarding the changes in epigenome-wide caused by particulate elements (PEs). Additionally, the potential pathways remain unknown. Objective: We evaluated whether short-term exposure to ambient PEs affects DNAm in epigenome-wide and identified potential biological pathways. Method: We collected whole blood samples from the Normative Aging Study (1999-2013) and measured epigenome-wide DNAm with the Illumina Infinium HumanMethylation450 BeadChip. Ambient PEs were measured daily at a fixed monitoring station and 7 different moving averages (from 1-day to 7-day) were considered. Linear models were used to estimate the associations between 14 elements and DNAm measured in baseline (N=774), adjusting for fine particle mass, cell type, batch effects, age, body mass index, smoking, etc. Pathway analysis was also performed to explore the potential biologic mechanisms. Results: Short-term exposure to PEs was significantly associated with epigenome-wide DNAm, especially for 2-d moving average. We observed 393 Bonferroni significant CpGs, most of them related with Aluminum, Silicon, Sulfur, and Potassium. The pathway analyses suggest that the detrimental effects might be relevant to immune response and signal transduction. We also found that there were several common genes significantly associated with Aluminum, Silicon and Sulfur, such as, Alzheimer's disease related gene Low density lipoprotein Receptor Related Protein 1; obesity-related gene Protein Tyrosine Phosphatase, Receptor Type F; and cancer related gene Lysophosphatidylcholine Acyltransferase 1. Conclusions: Ours is the first study that find short-term effects on DNAm in epigenome-wide by ambient PEs, especially elements associated with road dust, sulfate and wood burning. Our findings provide insight into potential mechanistic pathways.

### **P03.1210. Fe Concentration in Tree Barks: A Proxy for the Concentration of PM10**

Carmen Diva De André

*Carmen Diva S. De André<sup>1</sup>, Paulo A. André<sup>2</sup>, Tiana C. Moreira<sup>2</sup>, Luis F. Amato-Lourenço<sup>2</sup>, Ligia V. Barrozo<sup>4</sup>, Giuliano M. Locosselli<sup>3</sup>, Mitiko Saiki<sup>5</sup>, Julio D. Singer<sup>1</sup>, Paulo H. Saldiva<sup>2</sup>*

**Abstract:** Chemical element analysis in tree barks is being used to access the variability of urban air pollutant concentrations with high spatial resolution. We conducted an observational study in São Paulo, Brazil, where vehicle emissions are the main source of air pollution. **Aim:** Verify which trace elements in tree barks may be used as proxies for PM10 concentration in this urban scenario. **Methods:** Samples of barks from 498 trees (193 *Tipuana tipu*, 228 *Poincianella pluviosa* and 77 *Ligustrum* sp.) were collected near streets with different traffic intensities. Al, Ba, Ca, Cl, Cu, Fe, K, Mg, Mn, P, S, Sr and Zn concentrations were evaluated by energy dispersive X-ray fluorescence (EDXRF) spectrometry. Principal component analyses, considering robust correlation coefficients, were performed with the objective of identifying the sources of the chemical elements, with and without separation by species. Considering 14 trees located around air quality monitoring stations, the association between element concentrations in the tree barks and the annual PM10 (evaluated by Beta Attenuation method) mean concentration in the year preceding the bark sampling was evaluated via regression models. A forward stepwise procedure was adopted in the process of model fitting. **Results:** Regardless of species, the first principal component was related to vehicular emissions and explained 45% of the total variance. Fe was the element with the largest correlation with this component, both when a correlation matrix containing robust correlation coefficients was considered or not. In the fitting of the regression model, no other element related with vehicular sources had additional contribution to explain the PM10 variability ( $R^2=80\%$ ). **Conclusion:** Fe in tree barks may be used to access the spatial variability of long term PM10 concentrations. The results of this preliminary study are in line with recent research that proposes magnetic analysis of tree barks for air pollution biomonitoring purposes.

### **P03.1220. Susceptibility of Individuals with COPD to Air Pollution Exposure: A Case-Control Panel Study in Beijing, China**

Tong Zhu

*Tong Zhu<sup>1</sup>, Xi Chen<sup>1</sup>, Xinghua Qiu<sup>1</sup>, Chengli Que<sup>2</sup>, Lina Zhang<sup>3</sup>, Mei Zheng<sup>1</sup>, Qi Wang<sup>1</sup>, Wu Chen<sup>1</sup>, Yunfei Fan<sup>1</sup>, Yuan Yao<sup>1</sup>, Xiaoying Li<sup>1</sup>, Hanxiyue Zhang<sup>1</sup>*

**Abstract:** Introduction Chronic obstructive pulmonary disease (COPD) is one of the leading causes of death worldwide, characterized by chronic inflammation, and is one of the main diseases contribute to mortality attributable to PM<sub>2.5</sub>. Exposure to air pollution is one of the high-risk factors contributing to occurrence and development of COPD, it is important to reveal the biological mechanism of inflammation associated with exposure to air pollution in COPD patients and to know if subjects with COPD are more susceptible to air pollution than health one. Methodology With a case-control panel study (COPD), we recruited 44 stable COPD patients and 58 healthy control from Beijing Xicheng District Shichahai Community Health Center. Each subject has undergone 4 times repeated clinical visits from 2016 to 2017. Biomarkers, including breath volatile organic carbons, lung function, fractional exhaled nitric oxide (FeNO), fasting blood and cholesterol, inflammatory cytokines and cells, heart rate and blood oxygen were repeatedly collected from each subject in four visits. Gaseous air pollutants along with detailed chemical components and size distribution of particulate matter were continuously measured before and during each visits, 24 hours personal exposure to PM<sub>2.5</sub> of each subjects prior to clinical visit was measured with a personal PM<sub>2.5</sub> sampler. Linear mixed-effect model was fitted to estimate the association. Results Preliminary results shows increases in the levels of FeNO and heart rate, and decreases in the capabilities of pulmonary ventilation following air pollution exposure were more serious in the COPD patients, and adjusted by the forced expiratory volume. The association these effects with the exposure to CO, SO<sub>2</sub>, black carbon, organic carbon, and ultrafine particles were most robust. Conclusions After exposure to air pollution, the COPD patients had higher acute responses and worse capability of inflammatory regulation.

### **P03.1230. Airplane Pilot Performance in a Flight Simulator Under Varying Carbon Dioxide Concentrations**

Xiaodong Cao

*Xiaodong Cao<sup>1</sup>, Piers MacNaughton<sup>1</sup>, Jose Guillermo Cedeno-Laurent<sup>1</sup>, Skye Flanigan<sup>1</sup>, Jose Vallarino<sup>1</sup>, Deborah Donnelly-McLay<sup>1</sup>, Joseph G. Allen<sup>1</sup>*

*1. Environmental Health, Harvard T.H. Chan School of Public Health, Boston, MA, United States.*

**Abstract:** Recent studies suggest that carbon dioxide has an impact on cognitive functions of office workers at concentrations in the range of 1000-2500 ppm. Reports of CO<sub>2</sub> concentrations on airplanes are in the same range, so we were motivated to test the impact of CO<sub>2</sub> on airplane pilot performance. In this study, we recruited 30 active commercial airline pilots to fly three 3-hour flight segments in an FAA-approved flight simulator under three different CO<sub>2</sub> concentrations (700, 1500, 2500 ppm), each time blinded to test conditions and with the order of exposures randomized. CO<sub>2</sub> concentrations were directly modified by introducing ultra-pure CO<sub>2</sub> into the simulator with the ventilation rate unchanged. The pilots performed a series of pre-defined maneuvers of varying difficulty without the aid of autopilot and were assessed by an FAA Designated Pilot Examiner according to FAA Practical Test Standards. The results showed that airplane pilots performed better at lower CO<sub>2</sub> concentrations on the flight deck. Compared to segments at a CO<sub>2</sub> concentration of 2500 ppm, the odds of passing a maneuver as rated by the Examiner in the simulator were 1.52 (95% CI: 1.02 - 2.25) times higher when pilots were exposed to 1500 ppm and 1.69 (95% CI: 1.11 - 2.55) times higher when exposed to 700 ppm, controlling for maneuver difficulty, Examiner and order of maneuvers. The effect of CO<sub>2</sub> on passing rates became more pronounced the longer the pilots were in the simulator. These findings suggest that there is a direct effect of carbon dioxide on cognitive performance, independent of ventilation, with implications for many other indoor environments that routinely experience CO<sub>2</sub> concentrations above 1000 ppm.

### **P03.1240. The Effect of Seasonal Fine Dust Concentrations on the Well-Being of Citizens in Seoul**

KilYong Choi

*KilYong Choi<sup>1</sup>, SungChul Seo<sup>1</sup>, Sumin Lee<sup>1</sup>, Juheon Kim<sup>1</sup>, Kuk Cho<sup>1</sup>*

*1. Department of Environmental Engineering , Pusan National University, Busan, Korea (the Republic of).*

**Abstract:** Numerous research studies have been conducted on the effects, risks, and prevention of the exposure to aerial pollutants. Particulate matter and urban air pollution affect the human body and can lead to death. Epidemiological studies should consider the exposure to pollutants and the diverse responses of individuals depending on their sensitivity to the pollutants. In this study, air pollution measurements were obtained hourly at measuring stations operated by the national and local governments to increase the reliability of the measured values. A  $\beta$ -ray absorption method was used to analyze the measurements of fine dust and determine the particulate matter content. The air pollution data were log-converted to enable the comparison of data from different time periods. A seasonal analysis of the data indicated that the concentration of fine dust in Seoul was higher in the autumn, winter, and spring than in the summer. The data on individual characteristics were obtained from a survey of Seoul citizens conducted from 2014 to 2016 and using indicators such as the quality of life and social trust of Seoul citizens. The survey on the living environment and residence indicated that 80% of the heads of households were men. Women had a greater dissatisfaction than men with the residential, economic, and social environments. The survey questions on well-being were related to the internal and external environment such as air pollution, noise, and fine dust.

**P03.1250. Exposure to Air Pollutants and Variation of Blood Glucose Level among Gestational Diabetes Mellitus in China: A Retrospective Cohort Study**

Die Li

*Die Li<sup>1</sup>, Jian-bing Wang<sup>2</sup>, Zhe-Bin Yu<sup>1</sup>, Hong-bo Lin<sup>3</sup>, Kun Chen<sup>2</sup>*

*1. Zhejiang University, Hangzhou, China.*

*2. Research Center for Air Pollution and Health, Zhejiang University, Hangzhou, China.*

*3. Center for Disease Control and Prevention of Yinzhou District, Ningbo, China.*

**Abstract:** Background: Air pollution has been reported to be associated with risk of type 2 diabetes, but few studies were available for the associations with blood glucose level in pregnant women. Objectives: We aimed to examine the effects of exposure to air pollution on blood glucose in GDM patients in a retrospective cohort study. Methods: We identified GDM cases from hospital records among 35,722 women who were pregnant from January 2013 to May 2017. We used generalized additional models to estimate adverse effects of air pollution on fasting blood glucose and OGTT among GDM patients. Results: We identified a total of 1,347 women with GDM. An IQR increase in NO<sub>2</sub> exposure during the second trimester was associated with an increment of fasting blood glucose (FBG) level by 0.42mmol/L. Significant associations were observed among women with younger age ( $\beta=0.55$ ,  $p<0.05$  for CO), overweight/obesity ( $\beta=0.52$ ,  $p<0.05$  for NO<sub>2</sub>,  $\beta=0.70$ ,  $p<0.05$  for CO), lower education ( $\beta=1.08$ ,  $p<0.05$  for NO<sub>2</sub>,  $\beta=0.83$  for CO), and among manual labor ( $\beta=1.12$ ,  $p<0.05$  for NO<sub>2</sub>) and housewife ( $\beta=1.46$ ,  $p<0.05$  for CO). Our estimates for air pollutants (NO<sub>2</sub> and CO) and OGTT were generally consistent with the corresponding  $\beta$  values for FBG. No evidence was observed for the association between particle matter, SO<sub>2</sub> and Particle Matter exposure and FBG/OGTT level in our study. Conclusions: In the present study, women were at increased risk for higher blood glucose level when exposure to higher residential NO<sub>2</sub> and CO during their pregnancy. Women with higher BMI, lower education level were more susceptible to the adverse effects of ambient air pollution.

### **P03.1260. Daily Time in Transportation and Traffic by Urban Canadians**

Carlyn Matz

*Carlyn Matz<sup>1</sup>, Dave Stieb<sup>1</sup>, Marika Egyed<sup>1</sup>, Orly Brion<sup>1</sup>, Markey Johnson<sup>1</sup>*

*1. Health Canada, Ottawa, ON, Canada.*

Abstract: Traffic is an ever-present issue in urban centers and exposure to traffic and traffic-related air pollution is associated with wide-ranging health effects. Results from the Canadian Human Activity Pattern Survey (CHAPS) 2 were used to evaluate daily time spent in transportation and traffic by urban Canadians. It was estimated that Canadians spend 4-7% of daily time in on- or near-road locations, mainly from time spent in a vehicle with smaller contributions from time spent in active transportation. Furthermore, when in a vehicle, 44-61% of the target population was in moderate to heavy traffic. In addition, 11-22% of the target population was in moderate to heavy traffic while engaged in active transportation. Over 60% of the target population reported living near a busy roadway, which varied with income level and city of residence. People living near major roadways also spent more daily time in the vicinity of moderate to heavy traffic. Over 55% of the target population  $\leq 18$  years reported attending a school or daycare in close proximity to a busy roadway, with little variation based on income level and city. Overall, these results indicate that urban Canadians spend a considerable amount of daily time in transportation and traffic-influenced microenvironments. Quantitative measures of time spent in these microenvironments provide support for initiatives or strategies designed to mitigate population exposure to traffic and traffic-related air pollution.

**P03.1270. Long-Term Exposure to Ambient Air Pollution and Cognitive Function in Older U.S. Adults: The Multi-Ethnic Study of Atherosclerosis and Air Pollution**

Meng Wang

*Meng Wang<sup>1</sup>, Xiao-hua Zhou<sup>2</sup>, Cynthia Curl<sup>3</sup>, Annette Fitzpatrick<sup>4</sup>, Sverre Vedal<sup>1</sup>, Joel D. Kaufman<sup>1</sup>*

*1. Environmental and Occupational Health Sciences, University of Washington, Seattle, WA, United States.*

*2. Biostatistics, University of Washington, Seattle, WA, United States.*

*3. Community and Environmental Health, Boise State University, Boise, ID, United States.*

*4. Epidemiology, University of Washington, Seattle, WA, United States.*

Abstract: Background: Adverse effects of exposure to air pollution (AP) on cognitive function have been increasingly recognized. Little is known regarding whether specific sources of fine particulate (PM<sub>2.5</sub>) has more impact on cognitive function. Objectives: To evaluate the potential associations between long-term exposure to AP, including source-specific components in fine particles and cognition in older adults in the Multi-Ethnic Study of Atherosclerosis. Methods: Cognitive assessment, including the Cognitive Abilities Screening Instrument (CASI), Digit Symbol Coding (DSC), and Digit Span (DS), was completed in 4392 participants of mean age 70 in six areas of the United States during 2010-2012. Residence-specific AP exposures [i.e. oxides of nitrogen (NO<sub>2</sub>/NO<sub>x</sub>), PM<sub>2.5</sub> and its components: elemental carbon (EC), organic carbon (OC), sulfur (S) and silicon (Si)] were estimated by geo-statistical models. Linear regression models adjusted for individual-level characteristics were used to estimate the associations between each air pollutants and cognitive function. We also evaluated the effect of AP with race-specific low cognitive function (LCF) using a logistic regression model. Results: An interquartile (IQR) range increase in EC (0.8µg /m<sup>3</sup>) and Si (23.1ng /m<sup>3</sup>) was associated with -1.27 (95%CI: -0.09, -2.45) and -0.88 (95%CI: -0.21, -1.54) lower CASI score in global cognitive function. For each IQR increase in Si, the odds of LCF participants was 1.29 times higher (95%CI: 1.04-1.60) than the normal participants. For other tests, NO<sub>x</sub> was associated with slower processing speed (DSC: -2.01, 95%CI: -3.50, -0.52) and worse working memory (total DS: -0.4, 95%CI: -0.78, -0.01). No associations were found for PM<sub>2.5</sub> and its components (i.e. OC and S) with any cognitive function outcomes. Conclusion: Higher exposure to traffic-related air pollutants including both tailpipe (EC and NO<sub>x</sub>) and non-tailpipe (Si) species were associated with lower cognitive function in older adults.

### **P03.1280. High Environmental Ozone Levels and Extrinsic Skin Aging**

Tamara Schikowski

*Kateryna B. Fuks<sup>1</sup>, Anke Huels<sup>1</sup>, Dorothee Sugiri<sup>1</sup>, Jan Goebel<sup>3</sup>, Ilja Demuth<sup>2</sup>, Ursula Kraemer<sup>1</sup>, Jean Krutmann<sup>1</sup>, Tamara Schikowski<sup>1</sup>*

- 1. Epidemiology, IUF - Leibniz Research Institute for Environmental Medicine, Düsseldorf, Germany.*

- 3. German Institute for Economic Research, Berlin, Germany.*

**Abstract:** Introduction: We have recently reported a positive association of high levels of tropospheric ozone (O<sub>3</sub>) with extrinsic skin aging in the Berlin Aging Study II (BASE-II). In the current analysis, we combined two German cohorts and added a measure of an accumulated O<sub>3</sub> exposure. Material and Methods: We pooled two population-based cohorts: The older group of BASE-II participants (Berlin, 1,431 men and women aged 60-84) and the SALIA study (North Rhine-Westphalia, 806 women aged 67-80 years). We assessed facial coarse wrinkles and pigment spots as markers of extrinsic skin aging using the SCINEXATM tool. Five-year average residential exposure to O<sub>3</sub> at the postcode level was modelled with the Optimal Interpolation method by the Federal Environmental Office (Umweltbundesamt-FGII4.2) as (1) acute high exposure as count of days with maximal hourly concentration of O<sub>3</sub>  $\geq 120 \mu\text{g}/\text{m}^3$  ("exceedance") and (2) the accumulated daily exposure to O<sub>3</sub>  $\geq 40$  ppb from May to July ("AOT40"). We ran linear regression models, adjusting for age, sex, body mass index, education, smoking, alcohol consumption, and cohort. In a separate step, we adjusted for average residential ultraviolet (UV) erythemal dose in summer and co-pollutants coarse particulate matter (PM<sub>10</sub>) and nitrogen dioxide (NO<sub>2</sub>). Results: In the pooled analysis with two cohorts, O<sub>3</sub> was associated with more coarse wrinkles on the forehead: per 7 days of O<sub>3</sub> exceedance an increase by 7.6% (95%-CI: 1.1-14.1%), and per 2,000 ( $\mu\text{g}/\text{m}^3$ )\*h AOT40 by 4.1% (0.5-7.7%) in the wrinkles score. Both associations were robust to adjustment for UV and air pollutants PM<sub>10</sub> and NO<sub>2</sub>. We found no consistent associations between O<sub>3</sub> and pigment spots. Conclusion: Repeatedly high concentrations of ozone as well as accumulated O<sub>3</sub> exposure in summer were positively associated with coarse wrinkles, a marker of extrinsic skin aging. This association was independent from other air pollutants and UV exposure.

**P03.1300. Long-Term Exposure to Ambient Fine Particulate Matter and Liver Enzymes in 351,852 Adults: A Cross-Sectional Study**

Yacong Bo

Zilong Zhang<sup>1</sup>, Cui Guo<sup>1</sup>, Yacong Bo<sup>1</sup>, Xiang Qian Lao<sup>1</sup>

1. School of Public Health and Primary Care, The Chinese University of Hong Kong, Hong Kong, Hong Kong.

**Abstract:** Background: Animal experiments suggest that particulate matter can induce hepatotoxicity, but epidemiological evidence is scarce. We therefore investigated the associations between long-term exposure to fine particulate matter (PM<sub>2.5</sub>) and liver enzymes in a Taiwanese population. **Methods:** A cross-sectional analysis was carried out among 351,852 adults who participated in a standard medical screening program in Taiwan from 2001 to 2014. A venous blood sample was taken for the measurement of liver enzymes, including aspartate aminotransferase (AST), alanine aminotransferase (ALT) and  $\gamma$ -glutamyl transferase (GGT). A spatio-temporal model based on satellite-derived aerosol optical depth data was used to estimate ambient PM<sub>2.5</sub> concentrations at each participant's address. Linear regression models were used to investigate the associations between PM<sub>2.5</sub> exposure and liver enzymes. **Results:** Positive associations were found between PM<sub>2.5</sub> exposure and liver enzyme levels. After adjustment for a wide range of potential confounders, every 10  $\mu\text{g}/\text{m}^3$  increment in 2-year average PM<sub>2.5</sub> concentration was associated with 0.02% [95% confidence interval (CI): -0.04%, 0.08%], 0.61% (95% CI: 0.51%, 0.70%) and 1.60% (95% CI: 1.50%, 1.70%) increases in ALT and GGT levels, respectively. **Conclusions:** Long-term exposure to PM<sub>2.5</sub> is associated with increased liver enzyme levels, suggesting adverse effects of PM<sub>2.5</sub> exposure on liver function.

**Abstract:** Background/Aim: Epidemiological studies either use fixed site monitor measurements or modeled estimates at subjects' residential addresses to estimate health effects of short or long-term exposures. Recent developments in exposure modeling provide spatially resolved daily estimates enabling an integrated assessment of health effects arising from both long-and-short-term exposures. Our aim was to develop a spatio-temporal land use regression (LUR) model that estimates daily concentrations of nitrogen oxides (NO<sub>x</sub>), nitrogen dioxide (NO<sub>2</sub>) and ozone (O<sub>3</sub>), in London, UK. Methods: Data from the extensive network of fixed monitoring sites in London were collected for the years 2009-2013, while LUR variables were derived from Land Cover Map 2007. We obtained road geography and information on road traffic flows from the Department of Transport. We applied a semiparametric approach using spatial covariates, meteorological data, time varying variables and a bivariate smooth thin plate function. The final set of explanatory variables was selected based on the adjusted-R<sup>2</sup>. Moreover, we developed hybrid models by incorporating chemical transport modeling (CTM) predictions, obtained within the STEAM project for the same area and time-period, into the developed spatio-temporal LUR models. Results: The adjusted-R<sup>2</sup> of the developed LUR models was 0.75 for NO<sub>x</sub>, 0.72 for NO<sub>2</sub> and 0.69 for O<sub>3</sub>. We performed a ten-fold cross-validation and the adjusted-R<sup>2</sup> were 0.74, 0.71 and 0.62 for NO<sub>x</sub>, NO<sub>2</sub> and O<sub>3</sub> respectively. Incorporation of the dispersion estimates in the LUR models as a predictor, improved the LUR model fit: CV-R<sup>2</sup> increased to 0.77 for NO<sub>x</sub>, to 0.76 NO<sub>2</sub> and to 0.75 for O<sub>3</sub>. Conclusions: Our study supports the combined use of LUR and CTM in a single spatio-temporal modeling framework to improve the accuracy of predictions for subsequent use in epidemiological studies.

**Abstract:** Background and aims: Spatio-temporal methods have been developed for the estimation of concentrations of pollutants such as particulate matter (PM) and nitrogen dioxide (NO<sub>2</sub>) for application in epidemiological studies. A very limited number of city-specific spatio-temporal ozone (O<sub>3</sub>) models have been proposed recently. Our aim was to develop a spatio-temporal land use regression (LUR) model that estimates daily concentrations of O<sub>3</sub>, for the whole year, warm (April 1st to 30th September) and cold season (October 1st and 31st March), within the greater Athens area. Methods: We developed models using a semiparametric approach including linear and smooth functions of spatial and temporal covariates and a bivariate smooth thin plate function. The final set of explanatory variables was selected based on the adjusted-R<sup>2</sup>. We tested the final model in temporal and spatial terms following a leave-one out monitor approach. Results: The adjusted-R<sup>2</sup> of the developed annual model was 0.76, while for the warm and cold season it was 0.70 and 0.71, respectively. The spatial terms in our annual model explained 32.9% and the temporal 63.2% of the variability in O<sub>3</sub>. There was no remaining temporal or spatial autocorrelation in the residuals. The adjusted-R<sup>2</sup> in the leave-one-out cross validation was 0.73 for the annual model (warm: 0.65 and cold: 0.70). The developed models showed good validity when comparing predicted and observed measurements for the 2015 data. Conclusions: Spatio-temporal LUR modeling provides a useful tool for estimating O<sub>3</sub> spatio-temporal variability with adequate accuracy for subsequent use in epidemiological studies.

**P03.1340. Impacts of Air Pollution Wave on Years of Life Lost: A Crucial Way to Communicate the Health Risks of Air Pollution to the Public**

Abstract: Limited studies have explored the impacts of exposure to sustained high levels of air pollution (air pollution wave) on mortality. Given that the frequency, intensity and duration of air pollution wave has been increasing in highly polluted regions recently, understanding the impacts of air pollution wave is crucial. In this study, air pollution wave was defined as 2 or more consecutive days with air pollution index (API)>100. The impacts of air pollution wave on years of life lost (YLL) due to non-accidental, cardiovascular and respiratory deaths were evaluated by considering both consecutive days with high levels of air pollution and daily air pollution levels in Tianjin, China, from 2006 to 2011. The results showed the durational effect of consecutive days with high levels of air pollution was substantial in addition to the effect of daily air pollution. For instance, the durational effect was related to an increase in YLL of 116.6 (95% CI: 4.8, 228.5) years from non-accidental deaths when the air pollution wave was sustained for 4 days, while the corresponding daily air pollution's effect was 121.2 (95% CI: 55.2, 187.1) years. A better interpretation of the health risks of air pollution wave is crucial for air pollution control policy making and public health interventions.

**P03.1370. Short-Term Effects of Ambient Air Pollution Exposure on Lung Function: A Longitudinal Study among Healthy Primary School Children in China**

Chen Chen

*Chen Chen<sup>1</sup>, Chengcheng Li<sup>1</sup>, Yawei Li<sup>1</sup>, Jingyi Liu<sup>1</sup>, Congshen Meng<sup>1</sup>, Jingxiu Han<sup>1</sup>, Yawei Zhang<sup>2</sup>, Dongqun Xu<sup>1</sup>*

**Abstract:** Background: Short-term exposure to ambient air pollution has been associated with reduced lung function among asthmatic children. However, there is little information about the effects among healthy children, especially in areas with relatively high exposure background. Objective: To examine the association between short-term effects of ambient air pollutants and lung function among healthy primary school-aged children in China. Methods: A total of 334 healthy children (7-11 years) from four cities (Chengdu (Southwest China), Guangzhou (Southern China), Wuhan (Central China), and Xi'an (Northwest China)) in China with repeated lung function measurement in 2014-2016 were included. Daily ambient concentrations of PM<sub>2.5</sub>, PM<sub>10</sub>, NO<sub>2</sub>, SO<sub>2</sub>, mean temperature, and relative humidity data were obtained. Linear mixed model was used to estimate the percent change in lung function associated with per inter-quartile range (IQR) exposure (up to 3 days) increase after adjusting for confounders. Results: Ambient PM<sub>2.5</sub> and PM<sub>10</sub> exposure were significantly associated with decrements in FVC, FEV<sub>1</sub> and FEF<sub>25%</sub>. An IQR increase of two day average (lag01 day) PM<sub>10</sub> exposure (IQR, 144 $\mu$ g /m<sup>3</sup>) was significantly associated with 2.56% decrease in FVC, 5.46% in FEV<sub>1</sub>, and 7.35% in FEF<sub>25%</sub>. The effect estimates were stronger after adjusting for gaseous pollutants in particulate matter (PM) models. The strengths of these associations were stronger in girls than those in boys. Conclusion: Short-term exposure to PM<sub>2.5</sub> and PM<sub>10</sub> was associated with reduced FVC, FEV<sub>1</sub> and FEF<sub>25%</sub> in healthy children. The estimated adverse effects were greater in girls than in boys.

### **P03.1400. Impact of Air Pollution on Health in Abidjan Hospitals, Côte d'Ivoire**

**Abstract:** Background/Aim Air quality is catching the attention of public opinion due to its impact on human health. In Côte d'Ivoire, there is no national air quality measurement system. However, data concerning cardiorespiratory and skin diseases in relation to poor air quality exist. In order to estimate the impact of air pollution on health in the city of Abidjan and determine pollutants' concentration, a pilot survey was carried out in two Health centres in the municipality of Cocody. **Methods** The survey was conducted in January 2015. Data of patients with cardiovascular, respiratory and skin diseases at two health centres of Palmeraie and Akouedo village in Cocody, which may be related to air pollution were recorded. Every day during 15 days, investigators filled the survey sheet. The informations were related to age, sex, reason for consultation, diagnosis and treatment received. All records were verified and analysed in Epi info software. **Results** 286 people were enrolled for 1,450 consultations at the two health centres. Palmeraie health centre received 1060 patients over the period of the survey for a total of 167 enrolled persons (30.5%). However, the Akouedo village received 390 patients for 119 enrolled (15.8%). Overall, women and children aged 1 to 15 were the most important patients represented 57% and 60% respectively. Bronchodilators (66), corticosteroids (37), cardiac therapy and skin medication for eczema (36) were mostly prescribed by practitioners. **Conclusions** The health centre of Akouedo appears to be a major centre of patients with diseases related to air pollution where the biggest dump is located. This work also showed that Women and children most vulnerable people may be exposed to air pollution. A survey with the concentration of pollutants and the impact will allow us to know the real link between pollutants concentration and diseases related to air pollution.

### **P03.1410. Effects of Air Pollution on Behavior Change in Healthy Rats**

Hsiao-Chi Chuang

Abstract: Effect of air pollution on central nervous system (CNS) is poorly understood. The objective of this study is to investigate the roles of air pollution on CNS in rats. We established an experimental station nearby traffic emission sources in New Taipei City (Taiwan). The station equipped with ultrafine particle counter, DustTrakT II aerosol monitor, AEROTRAK nanoparticle aerosol monitor and MicroAeth black carbon monitor for particle monitoring as well as two exposure chambers for whole-body exposure of six-month-old SD rats (HEPA and PM2.5). After three months of exposure, rotarod performance test and novel object recognition (NOR) were performed. The daily average of particle number concentration (PNC) was 11599.2 cm<sup>-3</sup> with 53.1 nm in aerodynamic diameter. The PM2.5 mass concentration, black carbon (BC) and surface area concentration in alveolar region was 14.8 µg/m<sup>3</sup>, 1.8 µg/m<sup>3</sup> and 50.3 µm<sup>2</sup>/cm<sup>3</sup>, respectively. There was no significant difference in rotarod performance test between control group, HEPA group or PM2.5 group. Notably, we observed that the rats in PM2.5 group had the lowest NOR performance than the control and HEPA groups. In conclusion, sub-acute exposure to PM2.5 may have the effect on behavior changes in human.

### **P03.1420. Effect of Exposure to PM2.5 on the Fraction of Exhaled Nitric Oxide (FeNO): A Systematic Review and Meta-Analysis**

Liwen Zhang

Zhiyu Wang<sup>1</sup>, Tong Wang<sup>1</sup>, Jia Xu<sup>2</sup>, Bin Han<sup>3</sup>, Baiqi Wang<sup>1</sup>, Zhipeng Bai<sup>3</sup>, Naijun Tang<sup>1</sup>, Liwen Zhang<sup>1</sup>

2. Department of Environmental and Occupational Health Sciences, University of Washington, SEATTLE, WA, United States.

3. State Key Laboratory of Environmental Criteria and Risk Assessment, Chinese Research Academy of Environmental Sciences, Beijing, China.

**Abstract:** Background: Many epidemiological studies showed that exposure to air pollutants has been linked with increased airway inflammation and respiratory morbidity and mortality. However, the effect of ambient fine particulate matter (diameter <2.5mm) (PM2.5) on FeNO remains controversial. The aim of this systematic review and meta-analysis was to investigate the association between exposure to PM2.5 and FeNO. Methods: Articles were searched in those seven databases (PubMed, Web of Science, Embase, China Biology Medicine disc, China National Knowledge Infrastructure, Wanfang Data and Wanfang Med Online) before October 15, 2017. A random-effects model was used to calculate FeNO change for each increment of 10µg/m<sup>3</sup> in PM2.5. Results: In the 840 articles identified articles, 28 studies met our eligibility criteria. Estimates are given as the absolute-value-change in 12 studies and as the percent-change in 16 studies. The overall combined estimates showed an increase of 10 µg/m<sup>3</sup> in PM2.5 levels was associated with a 0.61 ppb (95% confidence interval, 0.46-0.76 ppb) increase in FeNO in the absolute-value-change studies and a 1.07% increase (95% confidence interval, 0.42%-1.71%) in the percent-change studies. Subgroup analysis was conducted according to age and disease. In most of the sub-group analysis, the heterogeneity remained significant. By sensitivity analyses we found the pooled estimate was not significantly changed after excluding cross-sectional studies and trial studies [0.59 ppb (95% CI 0.44-0.75 ppb) in the absolute change studies; 1.48% (95% CI 0.90%-2.06%) in the percent change studies]. For assessment of the publication bias by funnel plots and Egger's tests, no significant publication bias was found. Conclusion: The results suggested that at present research, short-term exposure of PM2.5 can increase levels of FeNO, which suggested an increment of airway inflammation. FeNO may be a sensitive airway inflammation marker of air pollution.

**P03.1430. Long-Term Exposure to Ambient Air Pollution and Cognitive Function in Older U.S. Adults: The Multi-Ethnic Study of Atherosclerosis and Air Pollution**

*2. University of Texas, Austin, TX, United States.*

**Abstract:** Background: On-road vehicles are a major source of air pollutant emissions. As a result, spatial patterns of air pollution near roadways have been studied exhaustively, and many spatial models such as land use regression (LUR) identify traffic as a main source of pollutant heterogeneity. However, relatively little is known about spatial patterns resulting from other common urban sources. Methods: We deployed an aerosol mass spectrometer (AMS), a state-of-the-art instrument for quantifying particulate matter (PM) composition, in a mobile laboratory. Measurements were conducted in Pittsburgh, PA and Oakland, CA. AMS provides real-time measurement of PM composition between organic and inorganic (sulfate, nitrate, ammonium) fractions, as well as full aerosol mass spectra of organic PM. Factor analysis of organic aerosol mass spectra allows for quantification of the contributions of both fresh emissions (e.g., traffic and cooking emissions) and aged secondary PM. Results: Urban spatial variations in PM exposure are dominated by fresh emissions, primarily from traffic and food cooking. Concentrations vary temporally, with higher traffic contributions in the morning and cooking dominating at midday and evening. In Pittsburgh, locations with both high traffic and high restaurant density have up to 2  $\mu\text{g m}^{-3}$  higher PM than the urban background. In Oakland, local traffic and cooking sources are more important than emissions from the large commercial port in driving pollutant spatial variations. Traffic also increases concentrations of secondary PM in downtown Oakland. The relationships between traffic- and cooking-emitted PM and typical land use variables is non-linear, which complicates the building of LUR models for source-specific PM. Conclusions: Source-resolved measurements of PM<sub>2.5</sub> reveal spatial patterns that cannot be described by traffic sources alone. Cooking is also an important determinant of PM<sub>2.5</sub> variations in US urban areas.

**P03.1440. Prenatal Exposure to PM2.5 in a Birth Cohort of Mexico City: The Influence of Season of the Year at Time of Conception**

**Abstract:** Background. Due to well established relevance of season on air pollution assessment, we estimated prenatal PM<sub>2.5</sub> (particulate matter < 2.5 microns) exposure by season of the year at different gestational ages. Methods. 944 pregnant women were georeferenced by home addresses between 2007 and 2011 in Mexico City. Prenatal exposure to PM<sub>2.5</sub> was estimated using methods of (i) proximity; (ii) proximity with imputed data; and (iii) hybrid satellite model. Non parametric Wilcoxon signed-rank tests were used to compare exposure methods, and root mean square error to measure the magnitude of differences. Results. Average exposure to PM<sub>2.5</sub> during all pregnancy ranged from 20.4 to 22.9 µg/m<sup>3</sup> No differences were found between methods for assigning exposure ( $p < 0.05$ ). Pregnancies that started in cold-dry season had a higher average concentration throughout the gestation period (25.7 to 26.3 µg / m<sup>3</sup>) compared to pregnancies that started during the rainy season (18.1 to 19.7 µg / m<sup>3</sup>). Conclusion. Variations in prenatal exposure levels were attributed to seasonal differences and not to the methods for assessing exposure. These results provided information about how changes to exposure based on season of conception are relevant to adverse birth outcomes.

### **P03.1450. The Effect on Bacterial Growth and Antimicrobial Activity in the Airway from Exposure to Ambient and Indoor Air Particles**

Emma Stapleton

**Abstract:** Human exposure to ambient air pollution causes a variety of cardiopulmonary health effects, including but not limited to upper respiratory tract infections, especially in susceptible populations. A byproduct of coal combustion, coal fly ash particulate matter, enhances bacterial growth in vitro, and decreases pulmonary antimicrobial activity ex vivo and in vitro. However, exposure to indoor air particles has not been studied. Bioluminescent *Staphylococcus aureus* was grown in minimal media with and without standard reference materials coal fly ash (CFA) and indoor air (IA) particles with an environmentally relevant dose of 10 and 50  $\mu\text{g}/\text{mL}$ . Bacterial growth increased significantly ( $p < 0.05$ ) after exposure to IA particles at two and three hours compared to vehicle control. To test the effect of particles on antimicrobial activity, we performed a bacterial challenge using airway surface liquid (ASL) from human donor cells. Immediate antimicrobial activity decreased in the presence of both CFA ( $p < 0.05$ ) and IA particles ( $p < 0.01$ ) at 50  $\mu\text{g}/\text{mL}$ , with a larger effect seen with IA particles ( $p < 0.01$ ). To verify whether the effect is limited to the large airway, we isolated ASL from pig cell cultures excised from small and large airways. In the large porcine ASL, IA particles had no effect at two different doses (50 and 100  $\mu\text{g}/\text{mL}$ ). However, CFA inhibited ASL killing at 100  $\mu\text{g}/\text{mL}$  ( $p < 0.05$ ). In the small airway, neither particle impaired ASL killing. Therefore, CFA inhibited ASL activity in large pig and human airway cells, and IA particles inhibited ASL activity only in human airway cells. These data suggest that exposure to indoor and ambient air particles do not impair ASL antimicrobial activity in the small airway; however, CFA and IA particles impair human ASL antimicrobial activity in the large airway. The data provide support for epidemiological findings of an increased rate of upper respiratory tract infections in populations exposed to ambient air pollution.

### **P03.1470. Disentangling Impacts of Multiple Nitrogen Dioxide Sources in an Urban Industrial Area**

**Abstract:** Air pollution monitoring campaigns support policy development and health effects research. To our knowledge, however, there have been few such campaigns in Philadelphia, and none have been designed to comprehensively evaluate pollution levels across the entire city. As an industrial city with a variety of pollutant sources, Philadelphia is an important setting for such a targeted program. We developed a spatially saturated monitoring campaign to separate impacts of different sources of Nitrogen Dioxide (NO<sub>2</sub>) (e.g., traffic, port activity) throughout the city. NO<sub>2</sub> was monitored across Philadelphia for a two-week period (January 15th to January 29th, 2018) using Ogawa passive samplers. Samplers were placed 8-9 feet high on telephone poles. A total of 50 sites were selected. Selection methods varied, but were based on maximizing spatial variability in NO<sub>2</sub> concentrations. Thirty-two were selected using a stratified random sampling approach with geographic information system based indicators of traffic density, proximity to navigable riverways, and population density, all dichotomized at the 80th percentile. Fourteen sites were chosen at varying distances upwind and downwind of a petroleum refinery and the Philadelphia International Airport. Four reference sites were chosen--two in city parks, one in a suburb upwind of Philadelphia, and one within close proximity of an Air Quality System (AQS) regulatory monitor. The mean NO<sub>2</sub> concentration across all monitoring sites was 22.79 parts per billion (ppb) (SD=3.75 ppb, min=10.48 ppb, max=30.12 ppb). A subset of sites will continue to be monitored every two weeks throughout 2018. Concentrations will be modeled using land use regression models to predict concentrations at unmonitored locations. This data will be used in future epidemiologic studies of effects of air pollution and other urban exposures on adverse health outcomes, including pediatric asthma.

**P03.1490. Domestic Fires for Cooking, Burning of Waste, and Motor Vehicle Emissions as Risk Factors for Increased Morbidity in Abidjan, Ivory Coast**

Isabella Annesi-Maesano

Abstract: Urban environments can harbor levels of air pollution threatening public health, outpacing other causes of death and creating elevated levels of disease. As city populations continue to rise, understanding urban pollutant concentrations becomes increasingly important and necessary for attributing contributions from specific urban activities, as well as in determining impacts on human health. Many studies relating negative health outcomes with poor air quality are focused on North America, Europe or China, and do not account for the specific weather patterns and rapid urban development of Western Africa, creating a gap in the understanding necessary to combat excess emissions. As part of the DACCIWA (Dynamics-aerosol-chemistry-cloud interactions in West Africa) project, we focus on the relations of three primary sources - domestic fires for cooking, waste burning, as well as vehicle emissions - with specific morbidities by examining three different neighborhoods within the city of Abidjan, each characterized by one of these sources. We related hospital visits and admissions data from six different hospitals within Abidjan to measurements of PM<sub>2.5</sub> concentrations, for both the rainy and dry seasons, between mid-2015 to mid-2017, in order to understand the risks associated with excess exposure in a tropical, coastal, urban environment. Overall, 13,965 hospital visits, including 3,372 hospital admissions for 2016, were observed. Using Health Impact Analysis (HIA), we estimated that annual number of hospital visits could be reduced by between 3.6% for those living near a waste-burning site and 3.8% for those living near heavy traffic and up to 24.9% for those living near high levels of domestic fire emissions, by reducing annual PM<sub>2.5</sub> emissions to align with WHO standards. Our data support the need for protecting individuals by comprehensively reducing air pollutant emissions.

### **P03.1500. Transmissometer Measurement of Black Carbon Is Sensitive to Reference Filter Characteristics**

Sreekanth Vakacherla

*3. Department of Civil and Environmental Engineering, University of Washington, Seattle, WA, United States.*

**Abstract:** Background: Black carbon (BC) aerosols are relevant to global climate and human health. Here we describe how reference filter characteristics can influence instrument-reported attenuation measurements (thereby BC estimates) using the OT21 (SootScan Optical Transmissometer, Magee Scientific, Berkeley, California, USA), which uses optical absorption. Objective: Quantify the sensitivity of OT21 attenuation measurements to reference filter characteristics and propose a correction. Methods: we used an OT21 to measure optical transmittance of aerosol-loaded filters (collected as part of the CHAI project, Hyderabad, India) relative to several reference (unexposed) filters at two wavelengths, corresponding to BC (880 nm, Infrared (IR)) and ultraviolet aerosols (370 nm, ultraviolet (UV)). Results: Instrument-reported sample attenuation varied with reference filter. For a given aerosol-loaded filter, instrument-reported attenuation was inversely related to reference-filter weight (e.g., higher instrument-reported for a sample measured against a lower-weight reference filter). This sensitivity can lead to substantial under- and over-estimation by the instrument (estimated mean absolute error:  $\sim 10$  and  $16$  ATN for IR and UV respectively). We report equations for correcting OT21 output, which allow use of any unexposed filter as the reference filter; application of equations reduced the error several-fold, to  $2$  and  $3$  ATN, respectively, for IR and UV ( $17\%$  and  $6\%$  errors, respectively).

**Abstract:** Introduction: Since radon (Rn) decay products are radioactive ultrafine particles that coagulate onto ambient particles, we hypothesize that Rn exposure may enhance effects of indoor pollution. Methods: Black carbon (BC) was measured up to 4 times over 12 months by reflectance in fine particle samples in homes of 85 COPD patients from 6 Massachusetts counties over a mean of 7.6 days. After indoor sampling, plasma C-reactive protein (CRP) was measured. Since current smokers and homes with major sources of BC were excluded, indoor BC was primarily of outdoor origin. County-specific Rn estimates were obtained from Berkeley National Laboratory estimates of living area annual averages (range 0.73-1.42 pCi/L). First, we estimated county-specific effects of BC on lnCRP, adjusting for season, age, BMI, diabetes, heart disease, race, temperature and relative humidity, and blood draw time using mixed effects models with a random intercept for each person. To assess whether county-specific BC effects varied by Rn, we regressed the county-specific BC effect estimates against Rn using inverse-variance weighting. To determine if other county level factors explained associations, we regressed county-specific BC estimates against county level measures of population density, % in poverty, % minority population, median household income, and education. Results: Median BC=0.19 µg/m<sup>3</sup> (IQR=0.22 µg/m<sup>3</sup>) over 285 observations. The effect of BC on lnCRP increased (p<0.0001) with greater county level concentrations of Rn. For every 0.5 pCi/L increase in county-average Rn, the BC effect (per IQR) increased by 0.23 (95% CI=0.20, 0.27) lnCRP (mg/L)/IQR. Other county level covariates did not display this pattern. Conclusions: County level Rn, but not county level sociodemographic factors, enhanced effects of indoor BC on plasma CRP in COPD patients. These observations suggest Rn may enhance the toxicity of indoor BC of outdoor origin.

### **P03.1530. Epidemiological Approaches to Morbidity Forecasting for Health Impact Assessment of Air Pollution**

Dave Stieb

*Guoliang Xi<sup>1</sup>, Dave Stieb<sup>2</sup>*

*1. Environmental Health Science and Research Bureau, Health Canada, Ottawa, ON, Canada.*

*2. Environmental Health Science and Research Bureau, Health Canada, Vancouver, BC, Canada.*

**Abstract:** Background: Forecasting future baseline morbidity rates is crucial to air pollution benefits assessment and disease burden analysis. Although numerous methods have been developed, no standard epidemiological approaches have been proposed. The purpose of this review is to provide an overview of available methods and examine sensitivity of forecasts to method selected. Methods: A literature search on morbidity forecasting was conducted using PubMed and Google Scholar. Sensitivity analyses were conducted using age-specific hospitalization rate data and population estimates. Results: Morbidity forecasting approaches can be grouped into standard regression models and dynamic microsimulation models. Regression models assume that predictor and dependent variables are uniformly correlated over time. However, this is not always the case. While the aging population is expected to increase morbidity, this may be partially offset by improved medical care and reduced exposures to risk factors like smoking. Dynamic microsimulation models have emerged as a reliable tool to address this evolution. The models simulate individuals' risks and health determinants, and consider alternative "what if" scenarios to accurately project health outcomes. Using a conventional forecasting method based on population age distribution and age-specific all-cause hospitalization rates in Canada, we found that the projected rate increased from 91 per 1,000 population in 2001-02 to 102 per 1,000 in 2015-16. Conversely, the observed rate in 2015-16 decreased to 84 per 1,000, indicating an overestimation of 20%. Results differ for specific causes of hospitalization. Several studies also found that neglecting demographic dynamics and using unadjusted age-expenditure profile could overestimate healthcare expenditure by between 10% and 20%. Conclusion: Demographic dynamics and other factors must be considered to ensure the accuracy of baseline morbidity projections in air pollution health impact assessment.

### **P03.1540. Quantification of the Burden of Disease Attributable to Nitrogen Dioxide Exposure in Germany**

Alexandra Schneider

*Alexandra E. Schneider<sup>1</sup>, Susanne Breitner<sup>1</sup>, Ute Kraus<sup>1</sup>, Josef Cyrys<sup>1</sup>, Myriam Tobollik<sup>2</sup>, Dietrich Plass<sup>2</sup>, Dirk Wintermeyer<sup>2</sup>, Volker Diegmann<sup>3</sup>, Annette Peters<sup>1</sup>*

- 1. Institute of Epidemiology, Helmholtz Zentrum München - German Research Center for Environmental Health, Neuherberg, Germany.*
- 2. German Environment Agency, Berlin, Germany.*
- 3. IVU Umwelt (GmbH), Freiburg, Germany.*

**Abstract:** Introduction: Epidemiological studies have shown associations of nitrogen dioxide (NO<sub>2</sub>) with numerous health outcomes. EU-wide air quality limit values for NO<sub>2</sub> are in place but regularly exceeded at measuring stations near roads in Germany. Therefore, a health risk assessment for the NO<sub>2</sub>-exposure of the German population was conducted. Methods: For 2007 to 2014, maps of the annual spatial 1\*1km<sup>2</sup> distribution of a population-weighted NO<sub>2</sub> concentration indicator were calculated. For three model regions a small scale assessment of the NO<sub>2</sub> exposure also considered concentrations in the higher resolved urban background and close to highly polluted street sections. A systematic literature search was performed to ascertain the current evidence on long-term health effects of NO<sub>2</sub> and to identify exposure-response-functions transferrable to Germany. The Environmental Burden of Disease-concept was applied to quantify the NO<sub>2</sub>-associated health risks for relevant outcomes. Results: The yearly mean background NO<sub>2</sub> slightly decreased from 13µg/m<sup>3</sup> in 2007 to 11.8µg/m<sup>3</sup> in 2014. Using a counterfactual value of 10µg/m<sup>3</sup>, 5,966 (95 %-confidence interval: 2,031 to 9,893) premature deaths and 49,726 (16,929 to 82,456) Years of Live Lost due to cardiovascular mortality attributable to NO<sub>2</sub> long-term exposure were estimated for 2014. Between 2007 and 2014 a decrease was observed for attributable premature deaths. The higher resolution of NO<sub>2</sub>-concentration for the three model regions led to a substantial increase in the estimated number of premature deaths due to cardiovascular disease by 40% to 165%. Discussion: The present estimates are based on NO<sub>2</sub> concentrations reflecting background exposure and thus underestimate the burden of disease. A better accuracy of the NO<sub>2</sub> exposure estimation accounting for the higher concentrations in urban areas close to traffic improves the burden of disease quantification and may enhance the distinction of health effects related to fine and ultrafine particles.

### **P03.1550. Governance of the Air in Bogotá: An Experience of Ecosystem Approach**

Luis Hernández

*Luis J. Hernández<sup>1</sup>*

*1. Public Health, Universidad de los Andes, Bogota, Colombia.*

**Abstract:** Introduction the Health Services participation in the monitoring air quality in Bogotá City is essential to guarantee quality of air governance; furthermore a direct communication channel is needed between citizens and Government. Currently Bogotá has 14 air monitoring stations and a Health Services Network organized in 4 sub-nets. The highest air pollutant is the PM 2.5, in Bogotá, mainly produced by the diesel automobile use. Objective Realize an Air Governance experience like an ecosystem strategy in Bogotá based on a model that allows not only citizen action to be visible, but also regional and national entities, in a differential way to achieve the air decontamination plans. Methodology The following governance strategies were applied whit the participation of University of Los Andes and Bogotá Health Secretary: A. Citizen capacities training in air pollution. b. Follow-up citizen of decontamination plans: identification of responsible sectors of the plan: mobility, industry, habitat and environmental sectors. Results In total 152 caregivers and 193 health professionals were trained in air governance, in Bogotá. An evaluation of knowledge, attitudes and practices in before-after training was carried out, 123 health professionals (63.7%) and 118 from community (77.6%), value  $p < 0.05$  indicated knowledge, attitudes and practices sufficiency to favor air governance. It is important to highlights that 60% were women. It was possible to establish 510 first level health services that show citizens the levels of air pollution; a 15% coverage equivalence. One (1) board to citizen control and monitoring was established for the air decontamination plans, which is visible on the web. Conclusion 1. Citizenship skills train is necessary in air quality improvement. 2. Air governance means making more visible the different responsibilities at the citizen level, health authorities, environmental authorities, but also Mobility and Habitat sectors in national and regional levels.

**P03.1560. Development, Application and Evaluation of Risk of Bias Criteria for Case-Crossover and Time-Series Studies of Air Pollution and Health**

Dave Stieb

*Dave Stieb<sup>1</sup>, Dina Salama<sup>2</sup>, Carine Zheng<sup>2</sup>, Ninon Lyrette<sup>1</sup>, Eric Lavigne<sup>1</sup>*

*2. University of Ottawa, Ottawa, ON, Canada.*

Abstract: Systematic review and meta-analysis methods are increasingly being applied to environmental health literature. However, these methods have not been routinely applied within the context of formal risk assessments, despite common aims and practices, including systematic identification, analysis and summary assessment of the weight of evidence linking exposures and outcomes. A particular gap in these practices is the availability of standardized criteria for assessing risk of bias in studies of environmental exposures, operationalized in a form that can be efficiently and reliably applied by reviewers / risk assessors to a potentially large number of primary studies. Building on the Navigation Guide systematic review methodology, we developed, applied and evaluated risk of bias criteria applicable to time series and case-crossover studies linking air pollution and cardiovascular and respiratory morbidity, operationalizing them in DistillerSRT systematic review software in the context of a systematic review of health effects of nitrogen dioxide. Risk of bias domains comprised: selection bias and generalizability, exposure assessment, confounding, outcome assessment, completeness of outcome data, selective outcome reporting, conflict of interest and other sources of bias. Risk of bias criteria were developed through literature review and expert consultation and evaluated with respect to content and face validity, inter-rater agreement and completion time. Our findings address the feasibility and reliability of our risk of bias criteria for time series and case-crossover studies linking air pollution and cardiovascular and respiratory morbidity. These criteria may provide a promising tool in the context of both systematic review and risk assessment. PROSPERO registration number CRD42018084497.

### **P03.1580. Short-Term Effects of Air Pollution on Cerebrovascular Diseases**

Mihye Lee

*Mihye Lee<sup>1</sup>, Sachiko Ohde<sup>1</sup>, Shinichi Ishimatsu<sup>2</sup>*

*1. St. Luke's School of Public Health, Tokyo, Japan.*

*2. St. Luke's Int'l Hospital, Tokyo, Japan.*

**Abstract:** Background/Aim PM2.5 is well-known to increase cerebrovascular diseases. However, there is a paucity of studies for the Japanese population, especially for Tokyo residents. In this study, we examined the association between exposure to hourly PM2.5 levels and acute cerebrovascular diseases using records on emergency department (ED) visit in Tokyo, Japan. Methods We used data on emergency department visits through ambulance dispatch (n=1,361,302) in the entire Tokyo prefecture from 2015 to 2016. Variables include date and time of incidence, age, sex, occurrence location at the ku-level (approx. ward or city level), and symptom/cause of dispatch recorded by paramedics. We selected non-traumatic cerebrovascular incidents (n=45,748). The PM2.5 data were acquired from the nearest air quality monitoring station to the occurrence location. Then, they were linked with the ED visits based on occurrence date and time. The bi-directional case-crossover study design was applied to investigate the acute cerebrovascular events controlling for ambient temperature, humidity, and day of week. Results A 10 µg/m<sup>3</sup> increase in PM2.5 level at the same hour was associated with a 1.01% (95% CI: 0.37 to 1.65) increase in ED visit related to cerebrovascular diseases. A stronger association was found in people aged between 50 and 70 (1.55%, 95% CI: 0.34 to 2.77). The same increase in PM2.5 was also associated with an increase in stroke (0.87%, 95%CI: 0.16 to 1.60). Conclusions Exposure to higher levels of PM2.5 was associated with increased ED visits pertinent to acute cerebrovascular diseases.

### **P03.1590. Is Non-Linear Concentration-Response Function between Daily Mean O3 Concentration and Mortality Biased?**

Sanghyuk Bae

*Sanghyuk Bae<sup>1</sup>, Yun-Chul Hong<sup>2</sup>*

*1. Department of Preventive Medicine, College of Medicine, Dankook University, Cheonan, Chungnam, Korea (the Republic of).*

*2. Department of Preventive Medicine, College of Medicine, Seoul National University, Seoul, Korea (the Republic of).*

**Abstract:** Background: The linearity of concentration-response (C-R) function between ambient O3 concentration and mortality has been controversial. Previous reports of non-linear C-R function has been suspected to be biased from unmeasured confounders. The aim of the present analysis is to examine the C-R function between O3 concentration and mortality with instrumental-variable approach. Methods: We extracted data of hourly meteorology, hourly O3 concentration and daily non-accidental mortality in Seoul from 2001 to 2009. We divided the dataset into two, odd-number (training set) and even-number years (testing set). Using the training set, we constructed a prediction model with support vector regression estimating the daily variations of mean O3 concentration caused by sun irradiance, wind speed and direction, uncorrelated with temperature and temporal trend. Then we predicted variance of daily O3 from the testing set using the prediction model, thus creating an instrumental variable. We analyzed the association between the instrumental variable and daily mortality. We also analyzed the association according to the different ranges of daily mean O3 concentration. Result: The cross-validated R2 was 0.20 and 0.15 for the prediction model with training set and testing set, respectively. The instrumental variable was significantly and negatively associated with daily mortality ( $\beta=-0.0042$ , SE=0.0009, P<0.0001). The negative slope of the association diminished as the quartile increased and the slope became positive in the 4th quartile (O3>29.7 ppb). The interaction between quartiles and instrumental variable was significant (P=0.0485). The slope was negative under 30 ppb of daily O3 concentration ( $\beta=-0.0041$ , SE=0.0011, P=0.0001), but it was positive over 30 ppb ( $\beta=0.0012$ , SE=0.0022, P=0.6000). Conclusion: We observed unequal C-R function between ambient O3 concentration and mortality according to the different ranges of daily mean O3 concentration with instrumental-variable approach.

### **P03.1600. Incorporating Individual Trajectories and Daily Activities in the Analysis of Exposure to Traffic-Related Air Pollution**

Maryam Shekarrizfard

*2. University of Toronto, Toronto, ON, Canada.*

*3. McGill University, Montreal, QC, Canada.*

**Abstract:** Traditional methods for evaluating population exposure generally ignore individual movements and only rely on a long-term average concentration at the home location. In this study, we evaluate individuals' mobility exposure to ultrafine particles (UFP), black carbon (BC) and noise which have been associated with pulmonary diseases, oxidative stress and functional disturbances. For this purpose, we assigned UFP, BC and noise predicted by land use regression models to trip and activity locations of individuals throughout the day. This approach is implemented in Toronto, Canada and highlights the advantages of the dynamic modelling of exposure compared to traditional methods. The comparison between at home exposure and daily mobility-based exposure reveals significant differences when relying on individuals' mobility compared to a daily average at the home location. We observed that mobility exposures were often more elevated than daily exposure at the home location. On average, individuals increased their UFP, BC and noise exposure by 11%, 6% and 9% while commuting and conducting activities out of home (compared to the daily concentration at home). We conclude that our proposed dynamic approach significantly improves the results of traditional methods that rely on a long-term average concentration at the home location and we shed light on the importance of using individual daily activities to understand exposure. In addition, we examined the effect of socio-economic characteristics and observed that exposure was more strongly associated with indicators that represent the mobility of individuals, such as age, employment status and transit pass ownership.

### **P03.1610. Short-Term Effects of Ambient Air Pollution on Cardiovascular Diseases and Respiratory Disease in Northern Vietnam**

Nhung Nguyen

*Nhung T. Nguyen<sup>1</sup>, Christian Schindler<sup>2</sup>, Dien M. Tran<sup>3</sup>, Chau Q. Ngo<sup>4</sup>, Hoang T. Le<sup>1</sup>, Hanh T. Phan<sup>4</sup>, Nguyen T. Linh<sup>5</sup>, Thanh T. Nguyen<sup>6</sup>, Nino Küenzli<sup>2</sup>*

- 1. Biostatistics, Hanoi Univerisity of Public Health, Hanoi, Viet Nam.*
- 2. Swiss Tropical and Public Health, Basel, Switzerland.*

- 4. Bach Mai hospital, Hanoi, Viet Nam.*
- 5. Epidemiology, Hanoi Univerisity of Public Health, Hanoi, Viet Nam.*
- 6. FIMO center, University of Engineering and Technology, Hanoi, Viet Nam.*

**Abstract:** Objectives: This study investigated the short-term effects ambient air pollution with hospital admissions due to respiratory diseases and cardiovascular diseases in three provinces in Northern Vietnam. Methods: Hospital records of residences living in three provinces Ha noi, Phu Tho and Quang Ninh (Northern Vietnam) from national and provinces hospitals were extracted. We also obtained hourly means of ambient air pollutants (PM10, PM2.5, PM1, NO2, SO2, CO and O3) and meteorological factors in each province. Quasi-Poisson models were used to estimate the association between outcomes and atmospheric pollutants, controlling for other factors such as meteorology, holiday and influenza epidemics in each province. Specified outcomes in the analyses are asthma, chronic bronchitis, stroke, ischemic heart diseases. Results: Most ambient air pollutants were associated with increases in daily hospital admission due to respiratory hospitalizations and cardiovascular diseases. The strongest effects had been found in nitrogen dioxide (NO2) for hospitalization due to stroke and pneumonia in all ages. For example, increments of an interquartile range in the four-day average (lag0-3) level of NO2 (25.3µg/m<sup>3</sup>) were associated with 2.3% (95%CI: 0.7% - 4.6%) and 6.1% (95% CI 2.5% to 9.8%) increase in daily counts of admissions for pneumonia and stroke in Hanoi, respectively. CO concentrations were negatively associated with daily hospitalization for asthma but positively with all other outcomes in all provinces. The findings indicated that the effects differ between age groups and seasons. Conclusion: The internal consistency of the results in three provinces with wide differences in pollution sources suggests that the association of ambient air pollutions and hospital admissions also applies to Vietnam. Though relative risks are small, the related burden is large, thus, further reductions in air pollution in Vietnam will provide large benefits.

### **P03.1630. Ambient Particulate Air Pollution and Circulating C-Reactive Protein Level: A Meta-Analysis**

Shaowei Wu

*Qisijing Liu<sup>1</sup>, Furong Deng<sup>1</sup>, Xinbiao Guo<sup>1</sup>, Shaowei Wu<sup>1</sup>*

*1. Department of Occupational and Environmental Health Sciences, School of Public Health, Beijing, China.*

**Abstract:** Background: Ambient particulate air pollution is a major threat to the cardiovascular health of the population. Inflammation is an important component of the pathophysiological process linking air pollution and cardiovascular disease (CVD). A classical marker of inflammation-C-reactive protein (CRP), has been recognized as an independent predictor of CVD risk. Exposure to ambient air pollutants may cause systemic inflammatory response but the association with CRP has been inconsistently reported. Objectives: We aims to estimate the effects of short-term and long-term exposures to ambient particulate air pollution on circulating CRP based on previous epidemiological studies. Methods: A systematic literature search of the PubMed, Web of Science, Embase, Scopus databases for publications up to January 2018 was conducted for studies reporting the association between ambient particulate matters (PM<sub>2.5</sub>, PM<sub>10</sub>) and circulating CRP level. We performed meta-analysis for associations reported in individual studies using a random-effect model and evaluated the effect modification by major potential confounders. Results: This meta-analysis comprised 243,960 participants from 37 observational studies carried out worldwide. Long-term exposure to particulate air pollution was much strongly associated with CRP level than short-term exposure. A 10 µg/m<sup>3</sup> increase of short-term exposure to PM<sub>2.5</sub> and PM<sub>10</sub> is associated with increases of 0.78% (95% CI: 0.22-1.33%) and 0.26% (95% CI:-0.03%,0.55%) in CRP level, respectively; and a 10 µg/m<sup>3</sup> increase of long-term exposure to PM<sub>2.5</sub> and PM<sub>10</sub> is associated with much higher increases of 18.49% (95%CI: 8.50-28.49%) and 11.10% (95%CI: 2.73-19.45%) in CRP level, respectively. Studies in Europe and North America showed stronger PM-CRP associations than studies in Asia. Conclusion: Exposure to ambient particulate air pollution is associated with elevated circulating CRP level.

**P03.1640. Association of Long Term Exposure of Particulate Matter 2.5 (PM2.5) and Cardio-Metabolic Diseases (CMDs) in Low & Middle Income Countries (LMICs): Systematic Review**

Suganthi Jaganathan

*Suganthi Jaganathan<sup>1</sup>, Gagandeep K. Walia<sup>2</sup>, Roopa Shivashankar<sup>1</sup>, Preet K. Dhillon<sup>2</sup>, Melina S. Magsumbol<sup>2</sup>, Safraj S. Hameed<sup>2</sup>, Prabhakaran Dorairaj<sup>2</sup>*

*1. Centre for Chronic Disease Control, NEW DELHI, DELHI, India.*

*2. PUBLIC HEALTH FOUNDATION OF INDIA, NEW DELHI, India.*

**Abstract:** Introduction: Numerous epidemiological studies indicated that high levels of particulate matter < 2.5 µm diameter (PM2.5) as a major risk factor for adverse cardiovascular effects on health. However, most of these studies have been conducted in high income countries (HICs), where average levels of PM2.5 are far less compared to LMICs and their socio-economic profile of the population, disease burden and PM speciation/composition are very different. We systematically reviewed the association of long term exposure to PM2.5 and cardio-metabolic diseases (CMDs) in LMICs. Methods: Multiple databases were searched for English articles with date limits until March 2018. For this review, we included studies investigating the association of long-term exposure to PM2.5 (defined as an annual average/average measure  $\geq$  3 days of PM2.5 exposure) and CMDs such as hospital admissions, prevalence and deaths due to CMDs, conducted in LMICs as defined by World Bank. Excluded studies which employed proxy measures for exposures, specific occupational groups, specific air pollution episodes and studies with poor quality as assessed by Cochrane risk of bias tool. Results: A total of 5567 unique articles were identified, of which 617 qualified for abstract screening and only 11 articles were included for full text review from eight countries (Brazil, Bulgaria, China, Ghana, India, Mexico, Russia and South Africa). With regards to outcome assessment, 2 studies evaluated hospital admissions & emergency room visits for CMDs, 5 studies on mortality, and 4 studies were on risk factors like blood pressure, obesity, etc. Largely a positive association between exposure to PM 2.5 and CMDs has been found. Diversity of air pollution measurement methods and health outcomes limited the ability to perform meta-analysis. Conclusion: Limited evidence on long-term exposure to PM 2.5 and CMDs in the LMIC context warrants long-term cohort studies to establish the association.

### **P03.1650. Ambient Air Pollution and Health Impact in China: A Review Based on Chinese Survey**

Guanghai Dong

*Guanghai Dong<sup>1</sup>, Xiaowen Zeng<sup>1</sup>, Boyi Yang<sup>1</sup>, Liwen Hu<sup>1</sup>, Zhengmin Qian<sup>2</sup>*

*1. Department of Environmental Health, School of Public Health, Sun Yat-sen University, Guangzhou, Guangdong, China.*

*2. Department of Epidemiology, College of Public Health and Social Justice, Saint Louis University, Saint Louis, MO, United States.*

**Abstract:** Background/Aim For the exposure-effect relationship of air pollution with health effect is non-linear, and the air pollution levels in developed countries were usually low (PM<sub>2.5</sub> mostly below 40 µg/m<sup>3</sup>), the results from developed countries may be not suitable in China where PM<sub>2.5</sub> levels were usually more than 120 µg/m<sup>3</sup>. Methods and Results We summary the results of our studies as following: 1) Air Pollution and Lung Cancer: Based on a cohort study of Northern China which a total of 39,054 participants aged 40-89 years were followed from 1998-2009, ambient PM<sub>10</sub> was positively associated with lung cancer mortality (HR per each 10 µg/m<sup>3</sup> = 1.65, 95% CI, 1.52-1.80), which was much higher than the IARC report (HR=1.08, 95%CI:1.00-1.07). 2) Air Pollution and CVDs in Chinese: Based on a cross-sectional study of 24,845 participants aged 18-74 years old, from 33 communities in Northeastern Chinese Cities, the adjusted odds ratio for stroke increased by 1.16 (95% CI, 1.03-1.30) per 19 µg/ m<sup>3</sup> increase in PM<sub>10</sub>. The associations of air pollutants with blood pressure were much stronger in populations with prehypertension than in the hypertensives. Diabetes is the most sensitive indicators for the impact of air pollutants on human health. 3) Air Pollution and Respiratory Health in Children: Study on 31,049 Chinese children, ages 2-14 years old in Seven Northeastern Cities during 2008-2009 found that 10 µg/m<sup>3</sup> increase of PM<sub>10</sub> resulted to a 38% (OR=1.35; 95%CI: 1.04-1.79) risk excess for asthma in children. The increased odds of lung function impairment ranged from 5% (aOR=1.05; 95%CI: 1.01, 1.10) for FVC < 85% predicted per 46.3 mg/m<sup>3</sup> for O<sub>3</sub> to 81% (aOR=1.81; 95%CI: 1.44, 2.28) for FEV<sub>1</sub> < 85% predicted per 30.6 mg/m<sup>3</sup> for PM<sub>10</sub>. Conclusions All these studies may prove to be effective preventative measures that could save lives and improve its quality, while reducing the economic and public health burden that plagues China and other industrialized nations.

### **P03.1660. Short-Term Exposure to Ozone and All-Cause Mortality in 95 Highly-Populated Japanese Cities**

Takehiro Michikawa

*Takehiro Michikawa<sup>1</sup>, Kayo Ueda<sup>2</sup>, Akinori Takami<sup>3</sup>, Seiji Sugata<sup>3</sup>, Ayako Yoshino<sup>3</sup>, Hiroshi Nitta<sup>1</sup>, Shin Yamazaki<sup>1</sup>*

- 1. Centre for Health and Environmental Risk Research, National Institute for Environmental Studies, Tsukuba, Ibaraki, Japan.*
- 2. Graduate School of Engineering, Kyoto University, Kyoto, Japan.*
- 3. Centre for Regional Environmental Research, National Institute for Environmental Studies, Tsukuba, Japan.*

**Abstract:** Introduction In Japan, ambient concentrations of ozone have been rising in Japan over the past few decades. Ozone is a classical air pollutant, and adversely affects human health. Therefore, updated health effect assessment for ozone would be informative to the regulation of ambient ozone. We examined the effects of ozone on non-accidental mortality by using a time-stratified case-crossover approach. Methods From the Japanese Ministry of Health, Labour and Welfare, we received mortality data in highly-populated 95 cities throughout Japan between the fiscal years 2012 and 2014. Hourly measurements of ozone, which were measured at one ambient air monitoring station within each city, were collected from the National Institute for Environmental Studies' atmosphere environment database. We calculated the daily maximum 8-h concentrations of ozone. We applied a conditional logistic regression model to estimate the city-specific association between ozone exposure and mortality, and then performed a meta-analysis of city-specific effect estimates. Results Average ozone concentration across 95 cities was 42.3 ppb (standard deviation = 15.2). Ozone exposure was positively associated with total non-accidental mortality (pooled percentage increase for 10 ppb increase in ozone at lag0-2 = 0.5, 95% confidence interval (CI) = 0.2 to 0.7). However, after adjustment for exposure to fine particulate matter (PM<sub>2.5</sub>), there was no association (percentage increase = 0, 95% CI = -0.3 to 0.3). In the PM<sub>2.5</sub>-adjusted model, ozone exposure increased only the risk of cardiovascular mortality (percentage increase = 1.3, 95% CI = 0 to 2.7). Conclusions In this study, short-term exposure to ozone was not clearly associated with mortality, but somewhat health effects were suspected.

**P03.1670. Google Street View Car Measurements of Traffic Related Air Pollution within Neighborhoods and Stroke in a Population with Preexisting Cardiovascular Disease**

Ananya Roy

*Ananya Roy<sup>1</sup>, Stacey Alexeeff<sup>2</sup>, Jun Shan<sup>2</sup>, Xi Liu<sup>2</sup>, Kyle Messier<sup>3</sup>, Joshua S. Apte<sup>3</sup>, Christopher Portier<sup>1</sup>, Stephen Sidney<sup>2</sup>, Stephen Van Den Eeden<sup>2</sup>*

**Abstract:** Background: An explosion of sensor technology allows for novel methods to assess long term exposures of Traffic Related Air Pollution (TRAP) at an unprecedented spatial resolution. Yet it is unknown if these highly resolved differences in street level TRAP and thus exposure differences between neighbors, are associated with clinical health outcomes. Objective: We explore the relationship between highly resolved spatial differences in TRAP and cardiovascular events among adults with prior cardiovascular disease (CVD) in Oakland CA. Methods: Sensors on Google Street View cars were used to measure and map annual day time median concentrations of nitrogen dioxide [NO<sub>2</sub>], nitric oxide [NO], and black carbon [BC] along 30 m road segments in Oakland, CA. These were linked to residential addresses of 1,810 adults with preexisting CVD living in the mapped areas, during 2010 to 2015, and members of Kaiser Permanente Northern California. We fit Cox proportional hazard models to estimate the relationship between air pollution exposures and time to first CVD event among those with preexisting CVD and estimated associations by elderly status while controlling for age, race, sex, BMI, smoking, socioeconomic status and comorbidities. Results: Among the 1,038 elderly with preexisting CVD (>65 yrs.) a 1 SD increase in NO<sub>2</sub> was associated with a 22% (95% confidence interval [CI] 3% to 44%) increase in stroke risk and a 4% (95% CI -6% to 16%) change in risk of any CVD event. Associations with NO were similar while associations with BC exposure were generally weaker. Among the 772 non-elderly adult population with preexisting CVD, most associations were weaker and not statistically significant. . Conclusion: Long term differences in NO<sub>2</sub> exposures between neighbors are associated with differences in stroke risks among the elderly who have preexisting CVD.

### **P03.1680. Impact of the Exposure to Traffic-Related Air Pollutants during Commuting by Foot on Children's Cognitive Development**

Ioar Rivas

*Ioar Rivas<sup>1</sup>, Mar Alvarez-Pedrerol<sup>2</sup>, Mónica López-Vicente<sup>2</sup>, Elisabet Suades-Gonzalez<sup>2</sup>, David Donaire<sup>2</sup>, Marta Cirach<sup>2</sup>, Montserrat de Castro<sup>2</sup>, Mikel Esnaola<sup>2</sup>, Xavier Basagaña<sup>2</sup>, Payam Davvand<sup>2</sup>, Mark Nieuwenhuijsen<sup>2</sup>, Jordi Sunyer<sup>2</sup>*

*2. ISGlobal, Barcelona, Spain.*

Abstract: Air pollution is suspected to have an effect on cognitive functions. Within the BREATHE project, we found that long-term exposure to traffic-related air pollutants (TRAPs) at school was linked to a lower cognitive development. Due to the proximity to the source, although commuting may be a relatively small amount of time, children may receive a high proportion of the daily TRAP. In a BREATHE subpopulation of 45 children, commuting corresponded to 6% of the time, but 20% of the Black Carbon (BC) daily dose. Despite the dose intensity of commutes, its impacts on neurodevelopment have not been studied. We aimed to assess the role of the exposure to TRAPs during the commute to school on cognitive development of schoolchildren. We carried out a longitudinal study including children from 39 schools in Barcelona (Catalonia, Spain) who commuted by foot to school (n=1,234). The children performed 4 computerized tests during 1 year follow-up to assess their developmental trajectories in WM (3-back numbers test) and inattentiveness. Average particulate matter  $\leq 2.5 \mu\text{m}$  (PM2.5), BC, and NO<sub>2</sub> concentrations were estimated for the shortest walking route by Land Use Regression. Differences in cognitive growth were evaluated with linear mixed effects models with age-by-pollutant interaction terms. An interquartile range (IQR) increase in PM2.5 concentration was associated with a reduction in WM of 5.4 (95%CI [-10.2,-0.6]) points. Similarly, for BC the reduction in WM was 4.6 (95%CI [-9.0,-0.1]) points. Findings for NO<sub>2</sub> were not conclusive. We found an increase in inattentiveness, although the association was not significant for any of the pollutants. The effects were independent to the exposure at home and at school. Exposures to PM2.5 and BC from commutes by foot were associated with a reduction in the growth of WM. The design and implantation of pedestrian school pathways through low traffic streets is encouraged in order to increase security and minimise children's exposure to TRAPs.

**P03.1690. Effects of Air Pollution and Land Use Characteristics on Development and Respiratory Health among Children in the Greater Taipei Area**

Abstract: Indoor and outdoor air pollution poses an important health threat to children. Exposure to air pollution may cause various acute and chronic respiratory diseases, and affect neurodevelopment and cognitive functions in children. To evaluate the impact of air pollution on children's health, we conduct a study to examine the effect of prenatal and early childhood exposure to air pollution on development and respiratory health in the first 3 years of life among a birth cohort in the Greater Taipei area. We will recruit 500 cohort children, and evaluate their development and respiratory diseases using standardized questionnaires and Bayley Scales of Infant and Toddler Development. One hundred children will be selected to conduct indoor and outdoor environmental samplings of their residences. Four hundred and fifty-six cohort children have been recruited so far, and environmental measurements have been implemented in 40 homes. According to our analyses, most ambient pollutant concentrations near participants' homes were lower than Taiwan National Ambient Air Quality Standard, except PM<sub>2.5</sub>, which exceeded the annual average level (15µg/m<sup>3</sup>). A few households had elevated indoor pollution levels due to a low ventilation rate or recent remodeling. Several children's bed dust samples contained dust mite allergen levels > 2 µg/g, which may increase the risk of child sensitization to dust mites. According to multiple regression analyses, a high level of nitrogen oxides during first trimester near residence as well as living near gas stations, social welfare facilities, or high ways had adverse effects on children's health; living near green parks was beneficial to children's neurodevelopment. Overall, residential environments, such as air quality and land use type nearby, may significantly influence children's health and neurodevelopment.

### **P03.1700. Exposure to Ambient Air Pollutants and the Onset of Dementia: An Administrative Cohort Study in Québec**

Abstract: Effects of air pollutants are related to oxidative stress which is also linked to the pathogenesis of dementia including Alzheimer's and associated diseases. We assessed associations between exposure to air pollutants and the onset of dementia; the association with the distance to major roads was also assessed for the island of Montreal. We created an open cohort of adults aged 65 years and older starting in 2000 in the province of Québec, Canada using linked medico-administrative databases. New cases of dementia were defined based on a validated algorithm. Annual residential levels of nitrogen dioxide (NO<sub>2</sub>) and fine particles (PM<sub>2.5</sub>) residential levels were estimated for each year of follow up using estimates based on satellite images and ground data. Hazard ratios (HRs) were assessed with Cox models with age as the time axis and stratified for sex, for the exposure at address at entry. Models were adjusted for the year, area-wide social and material deprivation indexes and for NO<sub>2</sub> or PM<sub>2.5</sub>; they were also indirectly adjusted for smoking. 1,807,133 persons (13,322,480 person-years) were followed and 237,569 developed dementia. HRs from adjusted models for an interquartile range increase in exposure at entry to NO<sub>2</sub> (15.49 ppb), PM<sub>2.5</sub> (4.67 µg/m<sup>3</sup>), and distance to major roads (147 m), were 1.015 (CI 95% 1.005-1.024), 1.021 (CI 95% 1.010-1.032) and 0.979 (CI 95% 0.967-0.990), respectively. Results suggest that the onset of dementia may be related to residential exposure to PM<sub>2.5</sub>, NO<sub>2</sub>, and distance to major roads. Acknowledgments: This work was supported by a Memorandum of Agreement with Health Canada.

### **P03.1710. Association of Particulate Matter Exposure and Depression: A Systematic Review and Meta-Analysis**

Harshal Salve

**Abstract:** Background Impact of particulate matter (PM) air pollution exposure and mental health conditions is generating lot of curiosity among public health practitioners and policy makers. We aimed to generate evidence on daily PM<sub>2.5</sub> and PM<sub>10</sub> exposure and depression. Methods A systematic search was conducted for published studies in English till December 2017. Independent two electronic searches were carried out in Medline, Web of Science and Cochrane Library using key words "Airborne Particulate Matter" OR "Air Pollutants" OR "Air Quality", "Outdoor Air Pollution" "PM<sub>2.5</sub>" "PM<sub>10</sub>" " Depression" "Depressive symptoms" "Mood disorder." We used Medical Subject Headings (MeSH) terms: "Particulate matter" and "Depression" in Medline and Cochrane Search. We have included articles reporting adjusted relative risk (RR) or odds ratio (OR) PM exposure and depression. References of the selected articles were also traced. Meta-analysis was performed to calculate pooled estimate using fixed effect model. Quality of studies was assessed using Newcastle-Ottawa Scale for observational studies. Protocol of the systematic review was registered in PROSPERO. Results We have got 938 records from all searched databases. Of which, 14 records were included for full text review after screening abstract and removing duplicates. Finally, eight articles were included for meta-analysis. Most of studies were longitudinal studies and spread out geographically across the regions. Daily PM<sub>2.5</sub> exposure was found to be associated with depression (RR=1.08, 95 CI: 1.02, 1.14) with acceptable heterogeneity (I<sup>2</sup>: 56%). Daily PM<sub>10</sub> exposure was not found to be associated with depression (RR = 1.01, 95% CI: 0.97,1.04). Age, sex, household income, education, co-morbidity and road traffic noise were adjusted as confounders. Conclusion We have found modest strength of association for daily PM<sub>2.5</sub> exposure and depression. Unknown confounders might have affected the pooled estimate from longitudinal studies in our analysis.

**P03.1720. Ambient Air Pollution and Completed Suicide in 26 South Korean Cities: Effect Modification by Demographic and Socioeconomic Factors**

Hyewon Lee

*1. Seoul National University Bundang Hospital, Seongnam, Korea (the Republic of).*

*2. Institute of Health and Environment, Seoul National University, Seoul, Korea (the Republic of).*

Abstract: Air pollution has been associated with suicide mortality. However, limited studies have examined possible effect modification of the association by various demographic and socioeconomic factors, despite their crucial roles on suicide risk. In 73,445 completed suicide cases from 26 South Korean cities from 2002-2013, we studied the association of suicide risk with exposure to particles <10  $\mu\text{m}$  (PM10), nitrogen dioxide (NO<sub>2</sub>), sulfur dioxide (SO<sub>2</sub>), ozone (O<sub>3</sub>), and carbon monoxide (CO), using a city-specific conditional logistic regression analysis with a case-crossover design. Random effects meta-analysis pooled the results. We considered a delayed effect of air pollution by constructing lags up to 7 days. We explored effect modification by demographic and socioeconomic factors (sex, age, education level, job, and marital status) as well as place of death, method of suicide, and season, through stratified subgroup analyses. Among five pollutants, NO<sub>2</sub> showed the strongest association at immediate lags (percent change in odds ratio; PM10: 1.2% [95% CI, 0.2%, 2.3%]; NO<sub>2</sub>: 4.3% [95% CI, 1.9%, 6.7%]; SO<sub>2</sub>: 2.2% [95% CI, 0.7%, 3.8%]; O<sub>3</sub>: 1.5% [95% CI, -0.3%, 3.2%]; and CO: 2.4% [95% CI, 0.9%, 3.8%] per interquartile range increase at lag0). In subgroup analyses by socioeconomic factors, stronger associations were observed in the male sex, the elderly, those with lower education status, white-collar workers, and the married; the largest association was an 11.0% increase (95% CI, 4.1%, 18.4%) by NO<sub>2</sub> among white-collar workers. We add evidence of effect modification of the association between air pollution exposure and suicide risk by various demographic and socioeconomic factors. These findings can serve as the basis for suicide prevention strategies by providing information regarding susceptible subgroups.

**P03.1750. Source Specific Air Pollution's Link to Hospitalizations and Emergency Department Visits for Influenza or Bacterial Pneumonia in Adults: The New York State Accountability Study**

Daniel Croft

*Daniel P. Croft<sup>1</sup>, Wangjian Zhang<sup>2</sup>, Shao Lin<sup>2</sup>, Sally Thurston<sup>1</sup>, Phil Hopke<sup>1</sup>, Mauro Masiol<sup>1</sup>, Stefania Squizzato<sup>1</sup>, Edwin van Wijngaarden<sup>1</sup>, David Rich<sup>1</sup>*

*2. Department of Environmental Health Sciences, SUNY Albany, Albany, NY, United States.*

Abstract: Fine particulate air pollution (PM<sub>2.5</sub>) has been linked to respiratory infections including influenza and bacterial pneumonia, but the response of respiratory infections to source specific PM concentrations (e.g. traffic, wood smoke) remains an area of active research. Using source specific PM<sub>2.5</sub> concentrations generated from Positive Matrix Factorization analyses at 6 urban sites in New York State (Buffalo, Rochester, Albany, Queens, Bronx, and Manhattan), we examined the association between source specific pollutants and the excess rate (ER) of hospitalizations and emergency department (ED) visits for influenza or bacterial pneumonia. We retrieved all hospital admissions and ED visits with a primary diagnosis of influenza or bacterial pneumonia from 2005 to 2016 from the Statewide Planning and Research Cooperative System (SPARCS) database. Using a case-crossover design and conditional logistic regression, we estimated the rate of influenza or bacterial pneumonia (for both hospitalizations and ED visits) associated with increased concentrations of source specific PM<sub>2.5</sub> including ammonium sulfate (AS), ammonium nitrate (AN), biomass burning (BB), pyrolyzed organic carbon (OP), road dust (RD), diesel (DES) and spark-ignition (GAS) vehicles. In preliminary analyses, interquartile range increases (IQR) in GAS concentrations in the previous 3 days were associated with an increased rate of influenza hospitalizations (ER = 13.8%; 95% CI: 5.4, 22.9) and ED visits (ER = 13.4%; 95% CI: 6.4, 20.8) with similar findings for DES and AN in both care settings. The association between bacterial pneumonia and source specific PM was inconsistent, with unexpected findings of reduced bacterial pneumonia hospitalizations associated with increases in both OP and DES, but increased ED visits associated with increases in RD. Future analyses will adjust for PM<sub>2.5</sub> mass, but increases in secondary PM<sub>2.5</sub> appear to be associated with an increased rate of influenza but not bacterial pneumonia.

**P03.1760. Epidemiological Study of PM2.5 and Its Chemical Constituents in a Small Residential City in Korea**

Abstract: PM2.5, defined as particles less than 2.5  $\mu\text{m}$  has been a great concern due to its significant adverse health effects, causing mostly respiratory and cardiovascular diseases. In Korea, PM2.5 concentration often exceeds the National Ambient Air Quality Standard of Korea as well as the WHO standard. PM2.5 concentrations in rural areas and even in background areas are often comparable with those measured in urban and industrial areas in Korea, indicating that long-range transport from regional sources may be important; however, most studies have been conducted in urban areas. In this study, the atmospheric concentrations of PM2.5 and its chemical constituents were measured in a small residential city of Korea from 2006 to 2012, and the association between PM2.5 and COPD-related hospital visits was evaluated. Data on hospital visits including admission and outpatient clinic visits for exacerbation of COPD were extracted from the National Health Insurance Service database. The average PM2.5 concentration was  $35.0 \pm 25.2 \mu\text{g}/\text{m}^3$  during the sampling period, and the number of daily hospital visits were  $6.42 \pm 4.28$  and  $2.07 \pm 1.93$  for males and females, respectively. The number of COPD-related hospital visits increased as PM2.5 increased. PM2.5 constituents including Al, Si, and elemental carbon were significantly associated with increased hospital visits. In the conference, the temporal trend and major characteristics of PM2.5 and its chemical constituents will be discussed in detail, along with an association between PM2.5 and the risk of COPE-related hospital visits.

**P03.1770. An Exploratory Analysis of the Effect of Regulatory Policies for Pre-Harvesting Sugarcane Straw Burning on Hospital Admissions for Respiratory Diseases in the State of São Paulo, Brazil**

Agnes Soares da Silva

*3. Departamento de Epidemiologia, Faculdade de Saúde Pública, Universidade de São Paulo, São Paulo, Brazil.*

Abstract: Emissions generated by sugarcane burning have been associated with acute respiratory effects and increase in hospital admissions, among other health effects. In 2002 the State of São Paulo (SP) approved a law that was adopted in 2003 that foresees the elimination of the practice of pre-harvesting sugarcane burn progressively up to the year 2031. This process has been accelerated through voluntary protocol agreements between the State and the producers, with incentives provided by the State, and pre-harvest sugarcane straw burn could have been eliminated in 2017. We analysed the trends in annual rates of hospital admissions for respiratory diseases in cities with the highest sugarcane plantations areas in the period 2000-2017. Data from hospitalization were obtained from the Hospital Information System (SIH/SUS) for respiratory diseases (J40, J44-47). Data from population were obtained from the Brazilian Institute of Geographic Statistics. Hospitalization rates were calculated for general population. To estimate sugar-cane plantation areas data, enhanced vegetation index from MODIS MOQ13 images was used. Ten cities with the largest plantation areas were selected. Data for pre-harvesting sugarcane burn were obtained from Spatial Research Institute and only the burns occurred in the sugar-cane plantation areas were included. All datasets were for the period 2000-2017. Trends in hospitalizations rates for all study cities were assessed by Prains-Winsten regression models. The time-series of pre-harvesting sugarcane burn, sugarcane plantation areas, and hospitalization rates did not present any trend ( $p>0.05$ ) in the study period. These preliminary results showed that legal measures to eliminate pre-harvesting sugarcane burn were not effective in any study city. Moreover, the period coincides with an expansion of the sugarcane plantation areas in São Paulo State. Thus, legal and voluntary measures have not proved to be sufficient to protect public health in the study area.

### **P03.1780. Effects of Particulate Air Pollution on Pulmonary Function among Healthy Students**

Yoshiko Yoda

- 2. National Institute of Technology, Yuge College, Kamijima, Ehime, Japan.*

**Abstract:** Background: Many epidemiological studies have reported that particulate air pollution was associated with exacerbation of respiratory diseases such as asthma. However, evidence about short-term effects of air pollution in healthy people is limited. We evaluated the effects of particulate air pollution on pulmonary function among healthy students in Japan twice a year for 3 years. Methods: A panel study was conducted of 48 healthy students who attended a school in an isolated island in the Seto Inland Sea, Japan. Peak expiratory flow (PEF) and forced expiratory volume in 1 s (FEV1) were repeatedly measured in every morning for each one month in spring and autumn from 2014 to 2016. Ambient concentrations of fine (PM<sub>2.5</sub>) and coarse (PM<sub>10-2.5</sub>) particulate matter and black carbon (BC) were measured on the roof of the school during the study period. Mixed-effects models were used to evaluate the associations of PEF and FEV1 with the average concentrations of air pollutants during the 24 h before a pulmonary function test. Results: The mean (SD) concentrations of PM<sub>2.5</sub>, PM<sub>10-2.5</sub> and BC were 23.5 (10.8), 15.3 (8.4) and 0.49 (0.28) µg/m<sup>3</sup>. Significant decreases in PEF were associated with PM<sub>2.5</sub> (-1.34% [95% confidence interval (CI): -1.88, -0.80] for an interquartile range (IQR) increase of 14.1 µg/m<sup>3</sup>) and BC (-1.02% [95%CI: -1.54, -0.50] for an IQR increase of 0.40 µg/m<sup>3</sup>). The decreases in FEV1 were also significantly associated with the increase in PM<sub>2.5</sub> and BC (-1.32% [95%CI: -1.99, -0.66] and -0.67% [95%CI: -1.32, -0.02], respectively). In seasonal analyses, the both effects of PM<sub>2.5</sub> and BC on pulmonary functions were significant in autumn. However, neither effects were significant in spring. No significant relationship between PM<sub>10-2.5</sub> and pulmonary function was observed throughout the study period. Conclusions: These results showed the effects of PM<sub>2.5</sub> and BC on pulmonary function among healthy students at considerably low levels.

**P03.1790. Air Pollution and the Burden of Childhood Asthma in the Contiguous United States in 2000 and 2010**

Haneen Khreis

*Raed Alotaibi<sup>1</sup>, Matthew Bechle<sup>2</sup>, Julian Marshall<sup>2</sup>, Tara Ramani<sup>1</sup>, Joe Zietsman<sup>1</sup>, Mark Nieuwenhuijsen<sup>3</sup>, Haneen Khreis<sup>1</sup>*

*3. ISGlobal, Centre for Research in Environmental Epidemiology (CREAL), Barcelona, Spain.*

**Abstract:** Background Emerging evidence suggests that traffic-related air pollution (TRAP) is associated with childhood asthma. However, no studies have estimated the burden of childhood asthma attributable to TRAP for the United States. We aimed to estimate the number of incident childhood asthma cases attributable to Nitrogen Dioxide (NO<sub>2</sub>) - a good marker of TRAP - in the Contiguous U.S. for the years 2000 and 2010. Methods Using a published national regression model, we estimated NO<sub>2</sub> exposures at the centroid of each U.S. Census Block and assigned that exposure to all children (birth - 18 years old) living in that Block. From the literature, we extracted a national average asthma incidence rate of 12.5 per 1,000 at-risk children/year and a concentration-response function of 1.05 (95% CI = 1.02, 1.07) per 4 µg/m<sup>3</sup> NO<sub>2</sub>. We calculated the relative risk, population attributable fraction and number of childhood asthma cases attributable to NO<sub>2</sub> exposures at each Census Block using a standard burden of disease assessment framework. We summed the attributable number of childhood asthma cases across the Contiguous U.S. Results NO<sub>2</sub> accounted for 209,058 (27%) incident cases of childhood asthma in 2000 and 141,931 (18%) in 2010. The reduction of cases was mainly due to a documented reduction in average NO<sub>2</sub> concentrations between 2000 and 2010 (18.7 µg/m<sup>3</sup> to 11.9 µg/m<sup>3</sup>). In current work, we are repeating this analysis with state-specific asthma incidence rates and with exposure to other pollutants including PM<sub>2.5</sub> and PM<sub>10</sub>. Conclusion A considerable proportion of new childhood asthma cases are attributable to NO<sub>2</sub> in the Contiguous U.S. We expect that TRAP-related cases would be preventable if TRAP emissions were reduced.

### **P03.1800. Ambient Air Pollution and Respiratory Diseases in Children in Jefferson County, Alabama**

Meghan Tipre

*Meghan Tipre<sup>3</sup>, Sreelatha Meleth<sup>2</sup>, Mark Leader<sup>3</sup>, Ilene Brill<sup>3</sup>, Jason Kirby<sup>1</sup>, Corey Masuca<sup>4</sup>, Tamika Smith<sup>3</sup>, Nalini Sathiakumar<sup>3</sup>*

- 4. Jefferson County Department of Health, Birmingham, AL, United States.*

**Abstract:** Introduction. Environmental air pollution is an important contributor to the global burden of respiratory disease among children. We examined the effects of PM<sub>10</sub>, ozone, PM<sub>2.5</sub> and its speciated compounds, on emergency department (ED) visits for respiratory diseases (RDs) among children, in Jefferson County (JC), Alabama. Methods. Daily exposure to air pollutants was characterized as county-wide aggregate and by residential zip codes. Daily counts of ED admissions for RDs, upper respiratory infections (URI) and asthma in children below 18 years of age were obtained from eight hospitals in JC. We used generalized additive model to evaluate associations, adjusting for seasonal and temporal trends, temperature, relative humidity, day of the week and age. Additionally, we used lagged models and stratification by seasons. Results. Using zip-code specific exposure, we found statistically significant positive associations between PM<sub>10</sub> and all RDs (RR, 1.003; 95%CI, 1.002 - 1.003), URI (RR, 1.002; 95%CI, 1.001 - 1.003) and asthma (RR, 1.005; 95%CI, 1.004 - 1.006), and between PM<sub>2.5</sub> and all RDs (RR, 1.002; 95% CI, 1.001 - 1.003), URI (RR, 1.001; 95%CI, 1.000 - 1.003), and asthma (RR, 1.003; 95%CI, 1.002 - 1.005). Similarly, significant positive association was noted for speciated pollutants, CO, EC, MMO, NH<sub>4</sub> NO<sub>3</sub>, OC, SO<sub>2</sub>, SO<sub>4</sub>, and TC pollutants and RDs, URI and asthma. Inconsistent associations were noted between ozone and all RDs. In lagged analyses, 0-2 days, 0-5 days, and 0-8 days moving-average lagged exposure had stronger association with disease outcomes compared to same day and single-day lagged exposure. No associations were noted between county-wide average PM<sub>2.5</sub>, PM<sub>10</sub>, and ozone, and RDs. Conclusion. Our results suggest that short-term exposures to PM and speciated pollutants may account for increased risk of paediatric ED visits for RDs. It may be optimal to characterize personal exposure within small units such as zip-codes compared to county-wide exposures.

### **P03.1820. Association between Household Solid Fuel Use and the Height of Children in China**

Xiaoli Duan

*Xiaoli Duan<sup>1</sup>*

*1. Environmental Engineering, University of Science and Technology Beijing, Beijing, Beijing, China.*

Abstract: Household air pollution from solid fuel combustion is one top environmental risk factor for many diseases and premature deaths, but few studies investigated postnatal exposure impacts of solid fuel use on children height. This study is to test the hypothesis that whether children from households using solid fuels are shorter than those using clean fuels. Heights of 59,112 children aged 1-17 years old are compared between the solid fuel and clean fuel groups with generalized linear models, adjusting for important risk factors including household income, second-hand smoke exposure, nutrition, education and occupations of parents. Significantly lower heights are observed for children living in households using traditional solid fuels for cooking during childhood, in line with prenatal exposure, which calls for effective and urgent actions on clean fuel interventions. Future mechanism studies are interesting.

### **P03.1830. Outdoor Air Pollution and Lung Function in Middle-Aged Adults of the ELISABET Study**

Anaïs Havet

*Anaïs Havet<sup>1</sup>, Sébastien Hulo<sup>1</sup>, Damien Cuny<sup>2</sup>, Florent Occelli<sup>2</sup>, Nathalie Cherot-Kornobis<sup>1</sup>, Jonathan Giovannelli<sup>3</sup>, Régis Matran<sup>1</sup>, Philippe Amouyel<sup>3</sup>, Jean-Louis Edmé<sup>1</sup>, Luc Dauchet<sup>3</sup>*

*1. Univ. Lille, CHU Lille, EA 4483 - IMPECS - IMPact de l'Environnement Chimique sur la Santé humaine, Lille, France.*

**Abstract:** The impact of long-term exposure to outdoor air pollution on lung function remains insufficiently studied in adults. Our aim was to study the associations between long-term exposure to outdoor air pollution, including industrial and urban exposures, and lung function in middle-aged adults. The analyses were conducted among 2994 adults (53 years old in average, 47% men) from the Enquête Littoral Souffle Air Biologie Environment (ELISABET, 2011-2013), a French cross-sectional survey. Air pollutant levels (NO<sub>2</sub>, PM<sub>10</sub> and SO<sub>2</sub>) were estimated at the participants' residential address by ATMO Nord-Pas-de-Calais, in Lille and Dunkirk urban areas. The lung function tests were performed according to the ATS/ERS guidelines, and FEV<sub>1</sub> (Forced Expiratory Volume in one second), FVC (Forced Vital Capacity), FEV<sub>1</sub>/FVC ratio and FEF<sub>25-75</sub> (Forced Expiratory Flow between 25 and 75% of the FVC) were used. Linear regression models adjusted for age, sex, height, year of inclusion, center, investigator, smoking status, body mass index, educational level and occupational exposure to dusts and fumes were conducted. An increase of 5 µg/m<sup>3</sup> in NO<sub>2</sub> was associated with lower FEV<sub>1</sub> (-1.37%, 95%CI -2.05 to -0.69), lower FVC (-0.84%, 95%CI -1.45 to -0.23), lower FEV<sub>1</sub>/FVC (-0.47%, 95%CI -0.77 to -0.17) and lower FEF<sub>25-75</sub> (-2.71%, 95%CI -4.20 to -1.21). An increase of 2 µg/m<sup>3</sup> in PM<sub>10</sub> was associated with lower FEV<sub>1</sub> (-1.31%, 95%CI -2.06 to -0.55), lower FVC (-0.81%, 95%CI -1.49 to -0.13), lower FEV<sub>1</sub>/FVC (-0.43%, 95%CI -0.77 to -0.10) and lower FEF<sub>25-75</sub> (-2.44%, 95%CI -4.10 to -0.78). An increase of 2 µg/m<sup>3</sup> in SO<sub>2</sub> was associated with lower FEV<sub>1</sub> (-1.33%, 95%CI -2.27 to -0.39), lower FEV<sub>1</sub>/FVC (-0.52%, 95%CI -0.92 to -0.11), lower FEF<sub>25-75</sub> (-2.70%, 95%CI -4.82 to -0.59), but was not significantly associated with lower FVC (-0.77%, 95%CI -1.62 to 0.09). Our results add evidence of the impact of urban and industrial outdoor air pollution on lung function in adults from northern France.

**P03.1840. Association of Biomass Fuel Use with Reduced Body Weight of Adult Ghanaian Women: Is it an Example of Reverse Causality?**

A. Kofi Amegah

*A. Kofi Amegah<sup>1</sup>, Johnmark Boachie<sup>1</sup>, Simo Nayha<sup>2</sup>, Jouni Jaakkola<sup>2</sup>*

*1. Biomedical Sciences, University of Cape Coast, Cape Coast, Ghana.*

*2. CERH, University of Oulu, Oulu, Finland.*

**Abstract:** Background: Smoking and ambient air pollution have been associated with body weight. Yet, the association of biomass fuel use with body weight has never been investigated in spite of the combustion pollutants sharing similar constituents with these environmental exposures. Objectives: We therefore examined the effect of biomass fuel use on body weight of adult women to provide insight into the obesity epidemic in Ghana and other sub-Saharan African countries. Methods: Data from the 2014 Ghana Demographic and Health Survey, a nationally representative population-based survey was analysed for this study. A total of 4,751 women who had anthropometric (height and weight) data qualified for inclusion in this study. Results: In linear regression modelling, use of charcoal resulted in 3.08 kg (95% CI: 2.04, 4.12) and 0.81 kg/m<sup>2</sup> (95% CI: 0.29, 1.33) reduction in weight and BMI, respectively. Use of wood also resulted in 7.77 kg (95% CI: 6.34, 9.20) and 2.49 kg/m<sup>2</sup> (95% CI: 1.77, 3.21) reduction in weight and BMI, respectively. In modified Poisson regression with logarithmic function, charcoal users had 19% (Adjusted Prevalence Ratio [aPR] = 0.81; 95%CI: 0.71, 0.92) and 29% (aPR = 0.71; 95%CI: 0.61, 0.83) decreased risk of overweight and obesity, respectively. Wood users had 37% (aPR = 0.63; 95%CI: 0.51, 0.78) and 61% (aPR = 0.39; 95%CI: 0.29, 0.52) decreased risk of overweight and obesity, respectively. Conclusions: The association of biomass fuel use with reduced body weight and BMI of Ghanaian women observed possibly reflects reverse causality from the weight loss triggering correlates of poor socioeconomic status. Elucidating the causal mechanisms through rigorous study designs is important to understanding the policy relevance of our findings.

### **P03.1850. PM2.5 Concentrations in Various Microenvironments and Exposure Prediction for Elderly Population**

Yu-Cheng Chen

*Wei-Ting Hsu<sup>1</sup>, Jyh-Larng Chen<sup>2</sup>, Shih-Chun C. Lung<sup>3</sup>, Yu-Cheng Chen<sup>1</sup>*

*2. Department of Environmental Engineering and Health, Yuanpei University of Medical Technology, Hsin Chu, Taiwan.*

*3. Research Center for Environmental Changes, Academia Sinica, Taipei, Taiwan.*

Abstract: This study was to investigate PM2.5 concentrations for various microenvironments indoor and outdoor in a city, north Taiwan. Personal PM2.5 exposure for elderly population was also predicted using a microenvironmental exposure (ME) model. More than 200 places and locations divided into 23 microenvironments by indoor, outdoor and transit modes were selected. A real-time monitor (SidePak, TSI Model AM510) was used to measure PM2.5 mass concentration (5-min interval) in each location for two hours at least in the warm and cold seasons during 2015-2017. The same type of the aerosol monitor was situated at the nearby air quality monitoring stations of the Taiwan EPA to simultaneously monitor ambient PM2.5. The results of the ME model, combining ambient/outdoor PM2.5, personal activity diaries, and microenvironment PM2.5 information, were validated with personal PM2.5 monitoring data. For indoor microenvironment, the restaurant and temple presented the highest concentration of PM2.5. For outdoor location, the traditional market and night market with relatively higher levels of PM2.5 were also observed. Riding a motorcycle could result in a higher PM2.5 exposure among transit activities. Considering personal time-activity patterns and time-weighted concentrations of PM2.5 in the microenvironments, we found home indoor exposure (90.2%) mainly attributed to total daily PM2.5 exposure for elderly, followed by transit (5.01%), other indoor (2.97%) and outdoor (1.81%) exposures. The model prediction performed well ( $R^2 = 0.83$ ) when outdoor PM2.5 was used as a surrogate compared with typically used ambient PM2.5 ( $R^2 = 0.64$ ).

### **P03.1860. Hazardous Emissions from the Partial Combustion of Aircraft Fluids**

Megan Steele

*Megan Steele<sup>1</sup>, Jerimiah Jackson<sup>1</sup>, Laura Flory<sup>1</sup>, Christin M. Grabinski<sup>1</sup>*

*1. United States Air Force School of Aerospace Medicine, 711 Human Performance Wing, Wright-Patterson, AFB, OH, United States.*

Abstract: Smoke events aboard aircraft occur in both commercial and military sectors and can potentially lead to health effects. In the event of a system failure, aircraft fluids can partially combust, and the emissions can enter the cabin through engine bleed air, exposing aircrew and passengers. In this study, five aircraft fluids were heated and burned in a cone calorimeter, and the emissions were characterized using a suite of aerosol and gas detection instruments. Real-time aerosol monitoring showed a high concentration of ultrafine particulate matter during the combustion process, while real-time gas monitoring showed elevated concentrations of carbon monoxide and hydrogen cyanide. Offline analysis of collected volatile organic compounds using gas chromatography–mass spectrometry revealed several potentially hazardous chemicals. Offline analysis of collected particles using transmission electron microscopy–energy dispersive X-ray spectroscopy resulted in observations of amorphous carbon chains, indicative of partial combustion. These results indicate that the partially combusted aircraft fluids tested could pose a health risk to those exposed to the emissions. Further, understanding the unique emission characteristics for different common aircraft fluids can help response personnel in tracking the origin of smoke events to system failures.

### **P03.1870. A Spatio-Temporal Prediction Model for Black Carbon Based on Automated Machine Learning**

Yara Abu Awad

Yara Abu Awad<sup>1</sup>, Mike Wolfson<sup>1</sup>, Choong-Min Kang<sup>1</sup>, Christine Choirat<sup>1</sup>, Petros Koutrakis<sup>1</sup>, Antonella Zanobetti<sup>1</sup>, Joel D. Schwartz<sup>1</sup>

**Abstract:** There is increasing evidence for the health effects of particles from transportation sources, with black carbon (BC) in particular gaining attention. The high spatial and temporal variation of exposure on a small scale can make the effects of this pollutant difficult to study. We previously fit a model using the machine learning (ML) methods support vector regression and simple gradient boosting to predict daily BC concentrations in Massachusetts, Rhode Island and southern New Hampshire. However, this model only went up to 2012 and while it did use ML methods, there have been significant advances in the ML field that can produce even better prediction models. We used automated machine learning (AutoML) which is a powerful and fast tool that can rescale data and then blend up to 15 ML algorithms in order to generate predictions. AutoML also carries out Bayesian hyperparameter tuning and iteratively improves with longer runtime. A total of 49,263 BC measurements from 371 monitors over a 16 year period (2000 to 2015) were obtained from various sources and calibrated for consistency. Both land use and temporal predictors were deployed, which allowed us to capture changes in spatial patterns of BC over time. We then input our data into the auto-sklearn package in python 3 and allowed it to run over 7 hours. The model showed good accuracy with an R2 of 0.80 in the held-out test data. We have successfully built a model that can be used to estimate long-term and daily exposures to ambient BC and will be useful for research looking at various health outcomes in MA, RI and Southern NH.

### **P03.1880. Endotoxin Concentrations in Airborne Particulate Matter and House Dust in Homes of Japanese Children**

Masayuki Shima

*Masayuki Shima<sup>1</sup>, Yoshiko Yoda<sup>1</sup>*

*1. Public Health, Hyogo College of Medicine, Nishinomiya, HYOGO, Japan.*

**Abstract:** Background: Endotoxins are an important biological component of particulate matter, and have been associated with adverse effects on human health. Many previous studies have evaluated endotoxin concentrations in house dust in the homes. However, there is no consensus on the association between airborne and dust endotoxin concentrations. Methods: We collected fine (PM<sub>2.5</sub>) and coarse (PM<sub>10-2.5</sub>) particulate matter for 7 days, inside and outside 287 homes of children who participated in the Japan Environment and Children's Study (JECS), from October 2015 to August 2017. In addition, dust samples were collected from mattress of the children. Endotoxin in both fractions of particulate matters and dust samples were measured using the kinetic Limulus Amebocyte Lysate assay. The relationships between endotoxin concentrations and household characteristics were evaluated for each fraction. Results: Outdoor endotoxin concentrations in both PM<sub>2.5</sub> and PM<sub>10-2.5</sub> were highest in autumn and lowest in winter. Indoor endotoxin concentrations in PM<sub>2.5</sub> were significantly higher in homes with carpet flooring and lower in homes that used air purifiers. Indoor endotoxin concentrations in PM<sub>10-2.5</sub> were higher in wooden houses than in houses of reinforced concrete. In both PM<sub>2.5</sub> and PM<sub>10-2.5</sub>, indoor endotoxin concentrations were higher than outdoor concentrations. In multivariate analyses, the indoor endotoxin concentrations in PM<sub>2.5</sub> and PM<sub>10-2.5</sub> significantly correlated with outdoor concentrations in each fraction (both  $p < 0.001$ ) and endotoxin levels in dust samples collected from mattress ( $p = 0.001$  and  $p < 0.001$ , respectively). Indoor endotoxin concentrations in PM<sub>2.5</sub> were also correlated positively with temperature, but no relationship between those in PM<sub>10-2.5</sub> and temperature was observed. Conclusions: These results showed that the indoor endotoxin concentrations were associated with the household characteristics including dust endotoxin in addition to outdoor endotoxin concentrations.

### **P03.1900. Using BenMAP for Assessing Health Impacts of Ozone Exposure: A Case Study in San Antonio**

Sonja Sax

*Sonja Sax<sup>1</sup>, Sue Kemball-Cook<sup>1</sup>, Bonyoung Koo<sup>1</sup>*

*1. Ramboll, Amherst, MA, United States.*

**Abstract:** The Environmental Benefits Mapping and Analysis Program (BenMAP) is used by the US Environmental Protection Agency (EPA) in regulatory impact and risk assessments. We used BenMAP to estimate the health impacts of changes in outdoor ozone to San Antonio, Texas residents. The 2017 ozone levels in the San Antonio area exceeded the 70 ppb National Ambient Air Quality Standard (NAAQS) for ozone. We estimated health impacts of changes in ozone levels from the 2010-2014 average (the baseline scenario) to a higher ozone scenario and a lower ozone scenario. Health outcomes included all-cause mortality, respiratory mortality, hospital admissions for respiratory and cardiovascular disease, emergency room visits for asthma, and school days lost. Respiratory mortality from long-term ozone exposures was the only health outcome for which statistically significant changes were estimated to occur due to changes in ozone levels. BenMAP estimated 19 (range of 13 to 25) respiratory deaths (2% of all annual respiratory deaths) would result from annual ozone increases from the 2010-2014 baseline to ozone levels in the higher ozone scenario (i.e., 2012 San Antonio ozone levels that exceed the current 70 ppb ozone NAAQS). Similarly, we estimated 24 (range of 17 to 32) deaths would be avoided as a result of ozone decreases from baseline to the lower ozone scenario that is lower than the NAAQS. The BenMAP results suggest a reduction in long-term respiratory mortality if ozone levels in San Antonio were reduced to a level that complies with the 70 ppb NAAQS and an increase in mortality from nonattainment. Study findings should be interpreted with caution because the biological mechanism for the effect of long-term ozone exposure on human health is not well understood. BenMAP relies only on evidence from epidemiological studies and these studies preclude a definite determination of causality due to their inherent limitations.

### **P03.1910. Short-Term Effects of Ultrafine Particles on Daily Mortality in Seven Spanish Cities**

Aurelio Tobias

*Aurelio Tobias<sup>1</sup>, Maria J. Bleda<sup>1</sup>, Elias Diaz<sup>2</sup>, Purificacion Lopez-Mahia<sup>3</sup>, Maria Piñeiro-Iglesias<sup>3</sup>, Cristina Reche<sup>1</sup>, Sergio Rodriguez<sup>4</sup>, Jesus de la Rosa<sup>5</sup>, Xavier Querol<sup>1</sup>*

- 3. Universidade da Coruña, A Coruña, Spain.*
- 4. Izaña Atmospheric Research Centre, Santa Cruz de Tenerife, Spain.*
- 5. University of Huelva, Huelva, Spain.*

**Abstract:** Background Epidemiological evidence on the short-term effects of ultrafine particles (UFP), with aerodynamic diameter <100 nm, on human health is still unclear. We investigated the relationship between UFP and daily mortality in seven Spanish cities, with urban environments affected by different sources of air pollution, where standardized measures are routinely collected. **Methods** We collected daily data non-accidental and cardiorespiratory mortality and UFP counts from urban and sub-urban background monitors, for (from North-to-South) A Coruña, Barcelona, Madrid, Huelva, Seville, Granada and Tenerife. Each city contributed with at least two cumulated years of data between 2008 and 2014. We applied city-specific quasi-Poisson regression models adjusted for trend, seasonality, temperature, weekdays and public holidays and pooled them with random-effects meta-analysis. **Results** Average UFP daily levels ranged from 3,361 particles/cm<sup>3</sup> in A Coruña to 18,192 in Huelva particles/cm<sup>3</sup>. We found a week effect at lag 1 for non-accidental mortality, increasing homogeneously the risk 1.06% (95% CI=[-0.05 to 2.18%], I<sup>2</sup>=0%) for a rise of 10,000 particles/cm<sup>3</sup>. Similar results were found for cardiovascular mortality, increasing the risk 2.05% (95% CI=[-0.03 to 4.13%], I<sup>2</sup>=1.5%). We did not find an association between UFP and respiratory mortality. **Conclusions** We found weak evidence of an association between daily ultrafine particles and mortality. As UFP are mainly generated by traffic in urban areas, our findings suggest an improvement of traffic emissions. However, more toxicological studies are required to determine the pattern and origin of UFP. **Acknowledgements** This study was supported by the National Plan for I+D+I (project PI15/00515) co-funded by the ISCIII Directorate General for Evaluation and the European Regional Development Fund (FEDER).

**P03.1920. Air Pollution and Pulse Wave Velocity in Young and Middle-Aged Asymptomatic Adults: The Kangbuk Samsung Health Study**

3. Center for Cohort Studies, Total Healthcare Center, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, Korea (the Republic of).

4. Department of Health Sciences and Technology, Samsung Advanced Institute for Health Sciences and Technology, Sungkyunkwan University, Seoul, Korea (the Republic of).

5. Department of Occupational and Environmental Medicine, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, Korea (the Republic of).

**Abstract:** Objective: Long-term exposure to fine particulate matter less than 2.5 µm in diameter (PM<sub>2.5</sub>) and less than 10 µm in diameter (PM<sub>10</sub>) are associated with cardiovascular risk. The mechanisms underlying these associations remains uncertain. We evaluated the association between long-term exposure to particulate matter and brachial-ankle pulse wave velocity (PWV), a marker of arterial stiffness, in a large sample of asymptomatic men and women. Methods: Cross-sectional analysis of 102,316 participants in the Kangbuk Samsung Health Study (KSHS) who underwent a comprehensive health screening examination in Seoul or Suwon, South Korea, between 2011 and 2016. We used participant-specific spatiotemporal pollution concentration models, incorporating agency monitoring data and geographical predictors, to estimate PM<sub>10</sub> and PM<sub>2.5</sub> concentrations between 2008 and 2016. We measured PWV using an oscillometric method with cuffs placed on both arms and ankles. Results: The monthly average particulate matter concentrations over 2011-2016 ranged from 22.6-113.2 and 4.8-57.9 µg/m<sup>3</sup> for PM<sub>10</sub> and PM<sub>2.5</sub>, respectively. The average PWV was 1307.2 cm/sec. In fully adjusted models, a 10 µg/m<sup>3</sup> increase in 12-, 36-, and 60-month PM<sub>10</sub> exposure was associated with a PWV increase of 4.11 (95% CI 0.75, 7.48), 6.19 (2.86, 9.53), and 4.87 (1.47, 8.26) cm/s, respectively. The corresponding increases in PWV associated with a 10 µg/m<sup>3</sup> increase in 12- and 36-month PM<sub>2.5</sub> exposure were 6.31 (1.61, 11.00) and 3.14 (-2.49, 8.76) cm/s, respectively. The association of particulate matter with PWV was evident in men and women, but it was significantly stronger in men compared to women. Conclusions: Increased concentrations of particulate matter were independently associated with brachial-ankle PWV in a large sample of young and middle-aged asymptomatic adults. Our findings add to the increasing body of evidence that identifies arterial stiffness as a mediator of the cardiovascular effects of air pollution.

**P03.1930. Exposure to Fine Particulate Matter of Vehicular Origin Is Associated with Increases in Blood Pressure among Hypertensive Outdoor Workers**

Carmen Diva de André

*Ubiratan D. Santos<sup>2</sup>, Alfésio L. Braga<sup>3</sup>, Maria Lucia B. Garcia<sup>3</sup>, Luiz Alberto A. Pereira<sup>3</sup>, Chin A. Lin<sup>3</sup>, Paulo Chiarelli<sup>3</sup>, Carmen Diva S. De André<sup>1</sup>, Paulo A. André<sup>3</sup>, Dante M. Giorgi<sup>2</sup>, Julio D. Singer<sup>1</sup>, Paulo H. Saldiva<sup>3</sup>*

- 1. Statistics, Institute of Mathematics and Statistics of University of São Paulo, São Paulo, Brazil.*
- 2. INCOR, São Paulo, Brazil.*
- 3. FMUSP, São Paulo, Brazil.*

**Abstract:** Hypertension and air pollution are two important risk factors for cardiovascular morbidity and mortality. Although several studies suggest that air pollution has a significant impact on blood pressure, studies on long-term effects are sparse and controversial. **Aims:** To evaluate the effects of exposure to different levels of traffic-generated PM<sub>2.5</sub> on blood pressure in outdoor workers. **Methods:** 88 non-smoking workers, exposed to different concentrations of vehicular pollution, were evaluated weekly in four successive weeks. At each evaluation, they underwent personal monitoring of 24-hour PM<sub>2.5</sub> concentration and 24-hour ambulatory blood pressure. The association between the blood pressure variables and PM<sub>2.5</sub>, adjusted for age, body mass index, time in job, daily work hours, diabetes or hypertension and cholesterol was assessed by means of multiple linear regression fitted by least squares. **Results:** Exposure to PM<sub>2.5</sub> (ranging from 8.5 to 89.7 µg/m<sup>3</sup>) was significant and consistently associated with an increase of blood pressure. An elevation of 10 µg/m<sup>3</sup> in the PM<sub>2.5</sub> concentration was associated with increments of 4.2 (CI 95%= [2.8; 5.6]) and 2.8 mmHg (CI 95%= [1.6, 4.0]) in average systolic and diastolic 24-hour blood pressure, respectively. **Conclusion:** Exposure to fine particles, predominantly from vehicular traffic, was associated with elevated blood pressure in hypertensive workers. Less relevant effects were observed in non-hypertensive workers.

### **P03.1940. Personal Exposure to PM2.5 and Its Bioreactivity in Healthy Adults of Hong Kong**

Kin-Fai Ho

*Xiao-Cui Chen<sup>1</sup>, Hsiao-Chi Chuang<sup>2</sup>, Ngai-Cheung Lau<sup>1</sup>, Hung-Lam Steve Yim<sup>1</sup>, Kin-Fai Ho<sup>1</sup>*

*1. The Chinese University of Hong Kong, Hong Kong, Hong Kong.*

*2. Taipei Medical University, Taipei, Taiwan.*

**Abstract:** Background: Mechanisms involving systemic inflammation have been proposed to explain the associations between PM2.5 with cardiopulmonary morbidity and mortality. Experimental evidence suggests that organic constituents in PM2.5 have critical health impact. However, there are limited studies related to the bioreactivity of personal PM2.5 in vitro with toxic components.

**Methods:** Personal monitoring from 58 (aged 18-42 years) healthy adults during the summer and winter were conducted in Hong Kong. Personal exposures to PM2.5 as well as its chemical components including organic carbon, elemental carbon, polycyclic aromatic hydrocarbons (PAHs), and phthalates in personal samples were determined. Additionally, the bioreactivity of personal PM2.5 in vitro were evaluated. Cell variability, 8-isoprostane, lactate dehydrogenase (LDH), and interleukin-6 (IL-6) released were used to determine the PM bioreactivity. Using the mixed-effects model, the relationships of bioreactivity to personal exposure to PM2.5 components were examined.

**Results:** Winter exposures were 1.6-2.0 times greater than summer exposures for personal PM2.5, EC, PAHs, and phthalate. Personal exposure to OC was significantly correlated with LDH ( $p < 0.05$ ) and IL-6 ( $p < 0.01$ ). Moderate correlations ( $r_s = 0.58$ ,  $p < 0.05$ ) were observed between OC and EC, but no correlations were observed between EC with bioreactivity of PM2.5. **Conclusion:** In vitro methods have an important role in the screening of bioreactivity of PM2.5. Results suggest exposure to PM2.5 components can induce cytotoxicity and system inflammation in healthy adults.

### **P03.1950. Exposure to Ambient Air Pollutants, Polycyclic Aromatic Hydrocarbons and Female Infertility**

Jufen Liu

*Jufen Liu<sup>1</sup>, Piye Niu<sup>2</sup>, Bin Wang<sup>1</sup>, Aiguo Ren<sup>1</sup>*

*1. Institute of Reproductive and Child Health , Peking University, Beijing, China.*

*2. Beijing Key Laboratory of Environmental Toxicology, Department of Occupational health and Environmental Health, School of Public Health,, Capital Medical University, Beijing, China.*

**Abstract:** Background: Environmental exposures can result in adverse effects on female reproduction. This study aimed to evaluate the correlation between ambient particulate matter exposure, especially polycyclic aromatic hydrocarbons (PAHs), and female infertility. Methods: Data came from a cohort case-control study of female fertility in rural China. Cases were women who were not pregnant after 1 years of unprotected sexual life among newly married couples, while the controls were women who became pregnant during the first year of marriage. Blood samples, 48 hours indoor and outdoor air exposure samples were collected. GC/MS was used to detect 16 US EPA-priority PAHs in blood and air sample. Results: Total 12 pairs cases and controls were analyzed in the current study. The mean age of the subjects was (23.7±2.8) years, most of them finished senior high school education, resided in the current place for (4.2±3.2) years. Recovery rate of 15 PAHs was (95.4±4.8)% with the range of (85.9-110)%. Total weight of PM in case group was significantly higher than control group, which was (0.011±0.011) mg and (0.007±0.002) mg respectively (P=0.014). The weight of coarse particulate matter(CP, 2.1-10µm), fine particulate matter(FP, <2.1µm) and ultrafine particulate matter(UFP, <0.43µm) and PM<sub>2.5</sub> was significantly higher in cases. The concentration of PM in case group was significantly higher than control group, which was (0.126±0.122) µg/m<sup>3</sup> and (0.091±0.037) µg/m<sup>3</sup> respectively (P=0.008), so did with every type of PM (CP, FP, UFP) and PM<sub>2.5</sub>. The concentration of L\_PAHs was (4.589± 4.954) µg/m<sup>3</sup> and (9.289±10.283) µg/m<sup>3</sup> in case and control group respectively (P=0.009), and the concentration of H\_PAHs was (6.566±5.774) µg/m<sup>3</sup> and (5.316±7.133) µg/m<sup>3</sup> (P=0.359). Blood concentration of ANY, FLU, FLO, PYR and BghiP were higher in cases than controls. Conclusions: Our findings suggest that women exposed to PAHs may be at increased risk of infertility. Confirmation by further research is needed.

### **P03.1960. Carbon Monoxide Poisoning in Ontario, Canada: Identifying Causes and at Risk Populations**

Elaina MacIntyre

*Elaina MacIntyre<sup>1</sup>, Katherina Chojnacki<sup>1</sup>, Denis Caza<sup>2</sup>, Robert Wiersma<sup>2</sup>, Ray Copes<sup>1</sup>*

*1. Environmental & Occupational Health, Public Health Ontario, Toronto, ON, Canada.*

*2. Technical Standards and Safety Authority, Toronto, ON, Canada.*

Abstract: Carbon monoxide (CO) poisoning results in a substantial public health burden, a burden that is entirely preventable. In Ontario, if emergency services identify CO during a 911 response they will notify the Technical Standards and Safety Authority (TSSA), who then conduct a detailed site investigation. Ten years of investigation data (2007-2016) was examined to identify predictors of CO incidents and characteristics of individuals exposed, to ultimately help inform prevention strategies. Detailed information on 2,780 unique CO incidents and 374 individuals who were exposed to CO was assessed. Examining CO incidents by month, a seasonal trend was evident, with a higher occurrence of incidents in cold months (November to February). Across all age categories, incidents where an individual was exposed to CO occurred primarily in homes (private and multi-unit dwellings) versus commercial, institutional and industrial settings. Incidents peaked between 8:00am and noon and virtually all CO incidents between midnight and 7:00am were in homes. The most common cause of a CO incident was improper installation, operation, or maintenance of equipment. There were a total of 15 fatal injuries, 140 serious injuries (poisoning), and 191 minor injuries (nausea/dizziness, aches/pains). 68% of the injuries impacted working age adults (20-59 years), and injuries peaked at 40-49 years (6 per 100,000 population). Nausea and dizziness were the most common symptoms reported. Half of the fatal injuries involved older adults (>60 years) at home. In order to inform successful prevention strategies around CO poisoning, routine surveillance of CO incidents is needed to understand how these events occur and to identify the population at risk. TSSA data provide unique information to inform prevention efforts, such as public education on the importance of regular maintenance of fuel-burning appliances.

### **P03.1970. Chemical and Physical Characterization of Tire Crumb Rubber Used in Synthetic Turf Fields to Improve Exposure Assessment**

Kent Thomas

*2. Agency for Toxic Substances and Disease Registry, Centers for Disease Control and Prevention, Atlanta, GA, United States.*

Abstract: Tire crumb rubber from recycled tires is widely used as infill material in the 12,000+ synthetic turf fields in the United States. Tire crumb rubber is a complex material, with many potential chemical substances, presenting challenges for assessing human exposures. As part of U.S. Federal Research Action Plan on Recycled Tire Crumb Used on Playing Fields and Playgrounds, researchers collected tire crumb rubber samples from nine tire recycling plants and infill from 25 outdoor and 15 indoor synthetic turf fields across the U.S. Fields were recruited from all four U.S. census regions, and ranged in age from new installations to 12 years old. Multiple analytical methods were applied to measure a wide range of metals, VOCs, and SVOCs. Particle sizes were characterized using gravimetric and SEM methods. Microwave acid digestion of tire crumb rubber with ICP-MS analysis was used to measure 20 elements. Tire crumb rubber was solvent extracted for analysis of approximately 50 PAHs, phthalates, thiazoles, and other rubber chemicals by GC/MS/MS and LC/TOFMS methods. Dynamic emission chamber testing was performed for VOCs and SVOCs at 25° and 60°C. Suspect screening and non-targeted analysis approaches were applied to assess the larger range of VOCs and SVOCs that may be associated with the material. Bioaccessibility of metals from tire crumb rubber was measured using simulated saliva, sweat, and gastric fluids. The range and variability in chemical substances measured within and between recycling plants and synthetic turf fields was examined. Differences in measurements among indoor and outdoor fields and fields with different age and region characteristics were assessed. This presentation will focus on key results from the application of this array of analytical methods, with a goal of improving our understanding and knowledge for assessing synthetic field user exposures.

### **P03.1980. Incorporating Mobile Monitoring Data in Spatio-Temporal Air Pollution Modeling**

Mei Tessum

*Mei Tessum<sup>1</sup>, Sverre Vedal<sup>1</sup>*

*1. University of Washington, Seattle, WA, United States.*

**Abstract:** Air pollution measurements from mobile platforms could potentially increase the accuracy of pollutant exposure prediction models. However, it can be challenging to separate spatial and temporal variability when including mobile measurements in exposure prediction models. This study investigates whether using mobile monitoring data in a spatio-temporal air pollution model can improve the performance of an exposure model in predicting NO<sub>2</sub> and NO<sub>x</sub> concentrations compared to a model created using only routine monitoring data. Three model scenarios were tested using a unified spatiotemporal modeling approach for the Los Angeles region from 2005 - 2014: 1) a model using two-week averaged AQS and the Multi-Ethnic Study of Atherosclerosis and Air Pollution (MESA Air) fixed site data only, 2) a model using those AQS and MESA Air fixed site data plus two-week averaged mobile monitoring data, and 3) a model using AQS and MESA Air fixed site data plus two-week averaged passive sampler data (concurrent and collocated with mobile monitoring). Additional measurements from MESA Air home sites were used for model validation. Models with either mobile monitoring data or passive sampler data improved model performance in home site predictions for both NO<sub>x</sub> and NO<sub>2</sub> compared to models developed from routine measurements only. Models using passive sampler data performed better than models created using mobile monitoring data. Results indicate that additional spatial information from mobile monitoring data can improve the spatio-temporal model performance, but passive sampler measurements may be preferable if available.

### **P03.1990. Fine-Scale Estimation of Air Pollutant Concentrations in an Urban Area Using a CMAQ-LUR Model**

Abstract: Studies on fine-scale air pollution modeling can improve the accuracy of the pollutant exposure assessment for a population in a complex urban environment. In this study, we predicted PM10 and NO2 concentrations at 100-m resolution using the land use regression (LUR) model based on Community Multiscale Quality (CMAQ) model and compared the differences between the simulated pollutant concentrations from the CMAQ-LUR and CMAQ models in the Seoul metropolitan region that experienced a high-concentration episode in 2016. The ArcGIS tool was used for analysis of predictor variables (land use, road, and altitude) and multiple regression analysis was performed using SPSS for statistical analysis of the LUR model. The developed CMAQ-LUR model simulated the high-resolution distributions of the daily mean PM10 and NO2 concentrations, showing higher concentrations at the intensive traffic network (highway and main road) and the industrial area; this result could be reasonably reproduced given the observational daily variations at several sites. When compared with the 1-km resolution CMAQ modeling results, the CMAQ-LUR model more clearly showed the heterogeneity of air pollution in an urban environment. Our study suggested that the CMAQ-LUR modeling approach can give reliable data for improving air pollutant exposure assessment of an urban population. *2. Harvard John A. Paulson School of Engineering and Applied Sciences, Harvard University, Cambridge, MA, United States.*

*3. School of Geography, Earth, and Environmental Sciences, University of Birmingham, Birmingham, United Kingdom.*

**Abstract:** Background-The burning of fossil fuels, especially coal and diesel, is a major source of airborne fine particulate matter (PM<sub>2.5</sub>), and air quality has been implicated as key contributor to the global burden of mortality and disease. We aimed to undertake a global assessment of mortality associated with air pollution from fossil fuel combustion among adult population. We also estimated mortality due to lower respiratory infections (LRI) among children under the age of five in North America, South America and Europe. Methods-Global PM<sub>2.5</sub> exposure levels were derived from the chemical transport model GEOS-Chem. Relative risks and attributable fractions of mortality were modeled using function from meta-analysis of association between long-term exposure to air pollutants and mortality. Results-We estimate a total global annual premature mortality attributable to the fossil-fuel component of PM<sub>2.5</sub> with 6,69 million deaths. Greatest mortality is simulated over regions with substantial higher change in the PM<sub>2.5</sub> concentration, notably parts of eastern North America, Europe, and Asia. We also estimated the excess annual deaths due to child LRI with 794 in North America, 619 in South America and 523 in Europe. Conclusion-This study demonstrates that the fossil fuel component of PM<sub>2.5</sub> does have an important mortality burden. By quantifying the health consequences of fossil fuel combustion, a clear message is sent to policymakers and stakeholders of the co-benefits of alternative energy sources.

**P03.2010. Air Health Trend Indicator: Association between Short-Term Exposure to Ground Ozone and Circulatory Hospitalizations in Canada for 17 Years, 1996-2012**

Hwashin Shin

*Hwashin H. Shin<sup>1</sup>, Lani Haque<sup>1</sup>, Harun Kalayci<sup>1</sup>, Branka Jovic<sup>1</sup>, Marc Smith-Doiron<sup>1</sup>, Wesley S. Burr<sup>2</sup>, Dave Stieb<sup>1</sup>*

- 1. Health Canada, Ottawa, ON, Canada.*
- 2. Mathematics, Trent University, Peterborough, ON, Canada.*

**Abstract:** Background: The Air Health Trend Indicator is part of the Canadian Environmental Sustainability Indicators program in Canada. It is designed to estimate public health risk related to short-term exposure to air pollution and to detect trends in the annual national health risks. Design: Daily ozone, hospitalization (three circulatory diseases) and weather data for 24 urban cities (about 54% of Canadians) over a period of 17 years (1996-2012) were used. Through a Bayesian hierarchical model an estimator using 7-year blocks was employed to find trends in annual national associations by season, lag of effect, sex and two age groups ( $\leq 65$  vs  $> 65$ ). Results: The Canadian population is growing and aging but getting healthier as hospitalization rates have declined from 10% to 8%. Females were hospitalized more than males (57% vs 43%) and circulatory hospitalization was about 16% of all causes. This study examined three circulatory causes: Ischaemic heart disease (IHD, ICD\_I20-I25, 40% of cases), other heart disease (OHD, ICD\_I30-I52, 31%) and cerebrovascular disease (CEV, ICD\_I60-I69, 14%). For warm season the baseline national risk per 10 ppb of 1-day lagged ozone was 0.4% (-0.3%~1.1%) for IHD, 0.7% (0.05%~1.3%) for OHD, and 0.2% (-0.8%~1.2%) for CEV. While an age effect was identified, more difference was detected by sex, with males more vulnerable to ozone for CEV and OHD. While IHD showed decreasing trends for recent years (2009 onwards) regardless age and sex, CEV did slightly increasing trends overall. In contrast, CEV did mixed trends by sex, with an increasing trend for males only. Discussions: The sex-specific differences in circulatory hospitalization risk need further investigations. The study findings could reduce knowledge gap by identifying sub-populations susceptible to ozone by season, age, sex and trend. The temporal trends in ozone's impact on circulatory hospitalization could help develop air pollution regulations.

### **P03.2020. A New Approach for Inferring Traffic-Related Air Pollution: Use of Radar-Calibrated Crowd-Sourced Traffic Data**

Markus Hilpert

*Markus Hilpert<sup>1</sup>, Mychal Johnson<sup>4</sup>, Marianthi-Anna Kioumourtzoglou<sup>1</sup>, Bernat Adria-Mora<sup>1</sup>, Anisia Peters<sup>3</sup>, James Ross<sup>2</sup>, Steven Chillrud<sup>2</sup>*

- 4. South Bronx Unite, New York, NY, United States.*

Abstract: Crowd-sourced traffic data potentially allow prediction of traffic-related air pollution at high temporal resolution. Our goals were to examine associations between (1) radar-based measurements of traffic and congestion colors displayed on Google Traffic (GT) maps and (2) black carbon (BC) levels and radar/GT data. At an off-ramp of an interstate and a small one-way street in a mixed-use area in New York City, we used radar devices to obtain vehicle speeds and flows (hourly counts) for cars and trucks. We downloaded in real time GT maps and assigned an ordinal variable GCC to the Google congestion colors (GCC increased with vehicle speed). BC levels were monitored with aethalometers. Flow was highest for intermediate speeds and GCC. Relationships between GCC, vehicle speed and flow were different for the two road types indicating local calibration of GT data is needed. Regression analyses showed that BC levels increase with vehicle flow. At the off-ramp, BC depended additionally on vehicle speed, which was negatively associated with BC levels. Time-dependent BC levels can be inferred from time-dependent GCC data and average vehicle flow (radar-derived in our case). Use of inexpensive crowd-sourced traffic data holds great promise for use in air pollution modeling.

**P03.2030. 3Z: STEPWISE: Tackling Urban Air Pollution in a Low Resource Setting: A Qualitative Study**

- 1. Health Center Zagreb - Center, Zagreb, Croatia.*
- 2. Epidemiology, Andrija Stampar Teaching Institute of Public Health, Zagreb, Croatia.*
- 3. Epidemiology, University of Rijeka, Rijeka, Croatia.*

Abstract: INTRODUCTION: Air pollution is a global rising problem and its ill effects on human health are well established. For the first time air pollution can be found among 10 greatest risks for premature death globally. 92% of the worlds population is living in an area where the air quality does not meet the pollutant levels recommended by the "WHO air quality guidelines". Croatia, especially the city of Zagreb is facing a rising traffic problem without a defined strategy on dealing with it and reducing its effects on human health. Stochastic action as a result of specialised scientific staff and knowledge base deficit has provided suboptimal performance. AIM: To create a framework for appropriate air pollution reduction intervention in urban environment using a combined qualitative approach. METHODS: A modified nominal group of epidemiology residents in Croatia will be used to pinpoint the main issues underlying the low efficacy of existing traffic air pollution reduction strategies. Using the results of nominal group, a ranking list of the main issues will be made, identifying the potential targets for air pollution reduction intervention. Systematic review of literature (SRL) will be conducted, using the PRISMA statement for reporting systematic reviews and meta-analyses of studies that evaluate health care interventions, to identify existing traffic air pollution reduction interventions in urban environments. RAND-UCLA appropriateness method, using inputs from the nominal group and SRL will be used to select the most appropriate intervention for the local setting. Policy recommendation will be made to facilitate implementation of selected intervention. CONCLUSION: This project will emphasise air pollution as a greatest environmental risk for its citizens with concluding policy recommendation for air pollution reduction and individual action plan.

**P03.2040. Ambient Air Pollution and Cardiopulmonary Morbidity Outcomes in Columbia, South Carolina, 1999 to 2015**

John Pearce

*John L. Pearce<sup>1</sup>, Matthew Bozigar<sup>1</sup>, Brian Neelon<sup>1</sup>, Kelly Hunt<sup>1</sup>, Adwoa Commodore<sup>1</sup>, Erik Svendsen<sup>1</sup>, John Vena<sup>1</sup>*

**Abstract:** Background: Much is still to be learned about the health effects of multiple air pollutants. Methods: We estimate acute health effects for single and multiple pollutants on multiple cardiopulmonary-related morbidity outcomes using time-series Poisson regression in Columbia, South Carolina between 1999 and 2015. Health outcomes included emergency department (ED) visits for asthma and upper respiratory infection (URI) and hospital admissions (HA) for congestive heart failure (CHF) and ischemic heart disease (IHD). Pollutants included daily measures of 1-hr max nitrogen dioxide (NO<sub>2</sub>) in ppb, 1-hr max sulfur dioxide (SO<sub>2</sub>) in ppb, 8-hr max ozone (O<sub>3</sub>) in ppb, and 24-hr particulate matter  $\leq$  2.5 microns (PM<sub>2.5</sub>) in  $\mu\text{g}/\text{m}^3$ . Multipollutant exposures were characterized using exposure categories defined by self-organizing maps based multipollutant day types (MDTs). Results: Single pollutant models found positive associations for 10-unit increases in PM<sub>2.5</sub> (asthma, IHD), O<sub>3</sub> (asthma, URI, CHF), SO<sub>2</sub> (asthma), and NO<sub>2</sub> (CHF, IHD), with the highest effects for asthma (RR: 1.014; 95%CI: 1.005-1.024). Multipollutant models found that, when compared to 'clean' air days, there were associations between the occurrence of four different MDTs exhibiting increasing pollution and increasing risk for two outcomes - asthma and IHD. The joint effects largest in magnitude were between asthma ED visits and days (MDT [2, 2]) experiencing elevated levels for all pollutants (RR: 1.023; 95%CI: 1.005-1.041). Conclusion: Using our framework, we found significant joint effects between multipollutant day types and cardiopulmonary morbidity.

**P03.2050. Impacts of Acute Changes in Air Pollution on Discharges from Implantable Cardioverter Defibrillators in Ontario, Canada**

Robin Shutt

*Robert Dales<sup>1</sup>, Mieczyslaw Szyszkowicz<sup>1</sup>, Robin Shutt<sup>1</sup>, Kumar Nanthakumar<sup>3</sup>, David Birnie<sup>4</sup>, Xuesong Wang<sup>2</sup>, Deva Thiruchelvam<sup>2</sup>, Sabit Cakmak<sup>1</sup>, Douglas Lee<sup>2</sup>*

- 3. Director of Heart Rhythm Disorders, University Health Network, Toronto, ON, Canada.*
- 4. Director Arrhythmia Service, University of Ottawa Heart Institute, Ottawa, ON, Canada.*

**Abstract:** Background: Acute changes in pollution have been associated with cardiac morbidity and mortality. Air pollution might impact cardiac morbidity and mortality through precipitation of cardiac arrhythmia in susceptible individuals. Despite gradual improvement in air quality over the past decades in North America, the links between days of higher pollution and cardiovascular morbidity and mortality still exist. This suggests that further research, at lower levels of ambient air pollution is warranted. The objective of this study is to examine the influence of acute changes in air pollution in Ontario, Canada on the frequency of discharges from implantable cardioverter defibrillators (ICDs) in response to cardiac arrhythmias. Methods: Using a case-crossover design, we compared ambient air pollution concentrations on the day of an ICD discharge to other days in the same month and year in 10320 patients with ICDs. We adjusted for weather, lagged the data from 0 to 3 days, and stratified the results by several patient-related characteristics. Results: Median (interquartile range) for SO<sub>2</sub>, NO<sub>2</sub>, ozone and PM<sub>2.5</sub>, were 1.0 ppb (0.4, 2.1), 10.0 ppb (6.0, 15.3), 26.0 ppb (19.4, 33.0) and 6.6 µg/m<sup>3</sup> (4.3,10.6) respectively. Odds ratios (95%CI) for an ICD discharge associated with an IQR increase in pollutant were 1.0 (0.91, 1.0) for SO<sub>2</sub>, 1.0 (0.9, 1.1) for NO<sub>2</sub>, 1.0 (0.9,1.1) for ozone, and 1.0 (0.9, 1.1) for PM<sub>2.5</sub>. Conclusion: Small day to day changes in air pollution at the relatively low levels seen in our study did not appear to be a risk factor for cardiac arrhythmias in patients with ICDs.

### P03. Global Health, Environmental Health Disparities and Other Social Issues 3

#### **P03.2070. Exposures to Volatile Organic Compounds (VOCs) among Rural and Urban Households in Southern India in Relation to Primary Cooking Fuels**

Naveen Puttaswamy

*Naveen Puttaswamy<sup>1</sup>, Srinivasan Natarajan<sup>1</sup>, Sudhakar Saidam<sup>1</sup>, Krishnendu Mukhopadhyay<sup>1</sup>, Sankar Sambandam<sup>1</sup>, Gurusamy Thangavel<sup>1</sup>, Kalpana Balakrishnan<sup>1</sup>*

*1. Environmental Health Engineering, Sri Ramachandra Medical College & Research Institute, Chennai, Tamilnadu, India.*

**Abstract:** Background: Emissions from cooking fuels that include many health damaging pollutants such as fine particulate matter and a range of polycyclic aromatic hydrocarbons and volatile organic compounds (VOCs) are a major public health concern in low and middle income countries (LMICs). Despite the ubiquity of exposures in India, VOC profiles in rural and urban households are poorly understood. Methods: We report results from cooking period measurements conducted in 112 (56 biomass, 23 kerosene and 34 gas using ) rural and urban households that were part of the larger Tamil Nadu Air Pollution and Health Effects (TAPHE) cohort study in Southern India. Samples were collected on a mixed-bed sorbent (Tenax and Carbopack) tubes. Active air sampling was performed using pre-calibrated constant flow pumps (SKC Inc., PA, USA) set to a flow rate of 0.1 L/min for 100 min. An automated thermal desorption unit connected to GC-MS system was used to quantify 59 VOCs. Pentafluorobenzene, 1,4-difluorobenzene and chlorobenzene-d5 were used as internal standards and percent recovery ranged from 81.7% to 119.9%. Results: Total VOC (TVOC) concentrations in rural homes (4426.8 µg/m<sup>3</sup>) were significantly higher when compared to urban homes (2010.9 µg/m<sup>3</sup>). Toluene, styrene, m,p-xylene and benzene were dominant in rural kitchens whereas toluene, m,p-xylene, benzene and isopropyltoluene were dominant in urban kitchens during cooking. Mean TVOC concentrations were the highest in biomass using homes (4617 µg/m<sup>3</sup>) followed by LPG (2839.7 µg/m<sup>3</sup>) and kerosene (1639.8 µg/m<sup>3</sup>) respectively. Benzene levels consistently exceeded the National Ambient Air Quality Guideline value of 5µg/m<sup>3</sup> in all rural and urban homes. Winter season, open field burning and industry nearby were associated with significantly higher VOC concentrations. Conclusions: Additional large scale assessments of population exposure to VOCs are needed in LMICs to better characterize health risks associated with solid fuel use.

### **P03.2080. Addressing Health and Environmental Impacts of Reliance on Solid Fuel and Kerosene for Cooking in Cameroon: Strengths and Challenges of the National LPG Masterplan**

Rachel Anderson de Cuevas

*Rachel M. Anderson de Cuevas<sup>4</sup>, Jessie Cooper<sup>1</sup>, Bessem Enonchong<sup>5</sup>, Sara Ronzi<sup>1</sup>, Elisa Puzzolo<sup>2</sup>, Bertrand Hugo Mbatchou Ngahane<sup>3</sup>, Nigel Bruce<sup>4</sup>, Daniel Pope<sup>1</sup>*

- 1. Public Health & Policy, University of Liverpool, Liverpool, United Kingdom.*
- 2. Public Health & Policy, University of Liverpool, Liverpool, United Kingdom.*
- 3. Douala General Hospital, Douala, Cameroon.*
- 4. Public Health & Policy, University of Liverpool, Liverpool, United Kingdom.*
- 5. Kosan Crisplant, Limbe, Cameroon.*

**Abstract:** Background: Cameroon relies on biomass fuel (mainly wood) for cooking, (88% rural population), with important health, deforestation and climatic consequences. The Government aims to increase Liquefied Petroleum Gas (LPG) use from < 20% to 58% of the population by 2035 and developed a Masterplan (2016) to achieve this goal via a multi-sectoral committee (ministries, national agencies, private sector and the Global LPG Partnership). An Investment Committee was established to oversee implementation. Objectives: To document and evaluate the Cameroon national process for LPG scale-up. Methods: The RE-AIM framework structured data collection and reporting: secondary data (socio-economic development, energy situation, policy); Masterplan documentation; LPG market expert and national stakeholder interviews; and LPG Adoption in Cameroon Evaluation (LACE) study data (community data on fuel use, stacking, barriers to LPG use, microloan schemes, impacts on particulate air pollution (PM2.5) and health). A logic model compared Masterplan proposals with issues reported by users and stakeholders. Findings: Masterplan recommended: €400 million investment to 2030 to increase LPG cylinders by 7 million, infrastructure developments (storage, transport, distribution and retail facilities), enhanced market regulation, national harmonisation of refill price and cylinder import tax reductions. The LACE studies highlighted user concerns about costs, safety, access, supply and cooking traditional foods. Stakeholders proposed increasing microfinance initiatives, LPG promotion, user support and health system engagement to promote clean fuels. Conclusions: The Masterplan has the potential to address problems of LPG access and supply and improve industry safety. Microfinance is supported and new pricing arrangements may lower cylinder deposit costs. Users' concerns (affordability, access, safety, traditional cooking) need consideration. Programme monitoring and evaluation is recommended.

### **P03.2090. Air Pollution and Childhood Respiratory Health in Nigeria**

Adetoun Mustapha

*Adetoun Mustapha<sup>1</sup>, Anna Hansell<sup>1</sup>*

*1. Epidemiology and Biostatistics, MRC-HPA Centre for Environment and Health , Imperial College London, Lagos, Nigeria.*

Abstract: Nigeria is projected to become the world's third most populous country by 2050. It has an oil-based economy and is a major emitter of green house gases from gas flaring. It is close to the Sahara desert, a major contributor to global dust. Nigeria has the third highest infant mortality rate in the world with about 20% caused by respiratory tracts infections. Epidemiologic studies have demonstrated decline of air pollution levels and improved respiratory health in children in developed countries. A literature search was conducted on Google Scholar to explore the extent to which cumulative exposure contributes to childhood respiratory health in Nigeria. The search was carried out on 28 March 2018 and limited to articles that were published in English Language since 2008. Additionally, the reference lists of relevant articles were manually checked. One hundred and twenty-five (125) full papers were assessed and 10 studies that measure exposure and respiratory health outcomes in children reviewed. The studies were mainly cross-sectional with varied exposure assessment methods. Reliable health data was lacking, recall method was used to collect information. Ambient or indoor air monitoring for PM, CO, SO<sub>2</sub>, NO<sub>2</sub> was done with portable monitors over a short period. In our earlier reported survey of 1397 children aged 7-14 years from low socio-economic schools in Warri (Mustapha et al, 2011), almost all the children (99.3%; 95% CI 98.8-99.7%) reported some form of school or home pollution from traffic fumes or open bush burning or cooking smoke (non-industrial) and gas flaring (industrial) at school or home. About two-third agreed that breathing clean air in various microenvironments prevents respiratory illness. Global health improvements require more interests in impact of air pollution on Nigerian population health. Further research is needed on how personal exposure related to the varied microenvironments contributes to the respiratory health of children in this region.

## **P03.2100. Clean Household Energy for Cooking in Low- and Middle- Income Settings: An Interdisciplinary Case Study Project to Advance Knowledge Translation**

Ashlinn Quinn

*Ashlinn K. Quinn<sup>1</sup>, Nigel Bruce<sup>2</sup>, Elisa Puzzolo<sup>2</sup>, Katherine L. Dickinson<sup>3</sup>, Rachel Sturke<sup>4</sup>, Darby Jack<sup>5</sup>, Sumi Mehta<sup>6</sup>, Anita Shankar<sup>7</sup>, Kenneth Sherr<sup>8</sup>, Joshua P. Rosenthal<sup>1</sup>*

*5. Columbia University, New York, NY, United States.*

*6. Vital Strategies, New York, NY, United States.*

*7. Johns Hopkins University, Baltimore, MD, United States.*

*8. University of Washington, Seattle, WA, United States.*

**Abstract:** Approximately 3 billion people rely on solid fuels and kerosene for their cooking needs. Exposure to household air pollution from burning these fuels accounts for approximately 3 million premature deaths a year. Clean fuels - such as liquefied petroleum gas (LPG), ethanol, biogas, electricity, and certain compressed biomass fuels - have the potential to alleviate much of this health burden, but to achieve health impact, uptake of the interventions must be widespread and sustained. Many clean fuel intervention programs are being implemented in low- and middle-income settings around the world, but few of these efforts have been evaluated. The Clean Cooking Implementation Science Network supported by the NIH and partners developed a set of eleven case studies, describing: LPG scale-up initiatives in Cameroon, Ghana, Indonesia, and Peru; biogas programs in Cambodia and East Africa; compressed biomass projects in Rwanda and China; alcohol fuel programs in Ethiopia and Nigeria; and a case in Ecuador covering LPG and electric induction cooking. We used RE-AIM (reach, effectiveness, adoption, implementation, maintenance) - an implementation science framework designed to organize and integrate information important in the translation of research to practice - to coordinate and evaluate the case studies. Results of this project include the eleven case studies themselves, a dataset that summarizes the programs using the RE-AIM framework, and a general conceptual model to support future planning and evaluation of household energy programs. Among the emergent results is the fact that traditional cooking practices tend to persist for multiple reasons (e.g. due to fuel supply interruptions, availability of free solid fuel, or cultural preferences) even when access and affordability are increased. Recommendations for such programs going forward are to include household-level monitoring of stove use patterns and to actively incentivize transition to near-exclusive clean fuel use.

**P03.2120. Urban and Rural Differences between Chemical and Social Environmental Risk Factors and Population Health, the Importance of Context**

Kristen Malecki

*Kristen Malecki<sup>1</sup>*

*1. Population Health Sciences, University of Wisconsin, Madison, Madison, WI, United States.*

Abstract: Relationships between social disadvantage and environmental exposures are complex and vary by geographic context and outcomes. However, few population-based studies have data to test these differences. The overarching goal of this study was first to examine the associations between cumulative socio-environmental stress and ambient air pollution with lung function then with body mass index (BMI) and examine how relationships differ in urban and rural contexts. Using data from 2400 adult participants of the Survey of the Health of Wisconsin, an additive socio-environmental stress index (SESI) was created from self-reported estimates of six social and built environment factors including self reported stress, poor neighborhood aesthetics, maintenance, presence of garbage and litter, limited safety from crime and lifetime discrimination. Three-year chronic air pollution exposure was estimated using USEPA's Bayesian space-time downscaler model for PM<sub>2.5</sub>. Both BMI and lung function were objectively measured during an exam visit. After careful adjustments, results showed no association between the non-chemical SESI and lung function in the overall study population. In contrast, three-year chronic air pollution was associated with reduced lung function ( $p < .03$ ). In fully adjusted models of chronic air pollution and lung function that tested for potential mediation by SESI, associations were slightly attenuated but remained significant. In stratified analyses, air pollution was only associated with reduced lung function in urban populations. Repeating analyses with body mass index as the primary outcome found opposite associations. Exposure to SESI but not chronic air pollution was a predictor of increased BMI ( $p < .001$ ). Stratified analyses revealed associations persisted in rural but not urban areas. Results highlight the importance of context in teasing out complex relationships between chemical and social environmental factors impacts on population health.

### **P03.2130. Polycyclic Aromatic Hydrocarbons and Their Oxygenated Derivatives in a Typical Small City in Northwest China: A Pilot Study**

Sa Liu

*Sa Liu<sup>1</sup>, Zhonghui Ye<sup>2</sup>, Patton K. Nguyen<sup>1</sup>, Panhong Gou<sup>2</sup>, Xiaoru Chang<sup>2</sup>, Yueli Yao<sup>2</sup>, Dong Wang<sup>2</sup>, Bin Luo<sup>2</sup>, Patrick Low<sup>1</sup>, S. Katharine Hammond<sup>1</sup>, Junling Wang<sup>2</sup>*

*1. Division of Environmental Health Sciences, School of Public Health, University of California, Berkeley, Berkeley, CA, United States.*

*2. Department of Toxicology, School of Public Health, Lanzhou University, Lanzhou, Gansu, China.*

**Abstract:** Due to severe ambient air pollution, Chinese government has taken tremendous effort to reduce air pollution and achieved noticeable progress. However, control strategies have been focused on major cities and key areas, leaving rural area and small cities largely unaddressed. This study examines ambient air pollution in Lintao, Gansu Province (a typical small city in northern China), in comparison with that was in Lanzhou, the provincial capital and largest city in northwest China, and the potential immunological effects in children living in these two cities. We collected air pollution samples at a selected study site in each city from December 2015 to June 2016, for polycyclic aromatic hydrocarbons (PAHs), oxygenated-PAHs (OPAHs) and PM<sub>2.5</sub>. We also acquired publicly available data and analyzed remote sensing data to complement measurement data. In addition, we collected limited simultaneous samples at multiple locations in each city to evaluate the spatial variation of pollutants. PAH samples were analyzed for 16 US EPA priority PAHs and 17 OPAHs. Blood samples were collected from children (n=21 in each city) and analyzed for immune markers reflecting T-regulatory (Treg) cell function. We found that although average PM<sub>2.5</sub> concentration in Lintao was marginally lower than it was in Lanzhou (55 vs. 66  $\mu\text{g}/\text{m}^3$ ), PAH and OPAH concentrations (sum of 16 PAHs and 17 OPAHs, respectively) were actually much higher in Lintao than in Lanzhou (495 vs. 218  $\text{ng}/\text{m}^3$  and 139 vs. 102  $\text{ng}/\text{m}^3$ , respectively). Notably, we observed lower gene expressions for immune transcription factors and cytokines in children living in Lintao, suggesting impaired Treg cell function potentially related to PAH/OPAH exposure in Lintao. We hypothesized that the use of coal and biomass in Lintao was the major reason for the high PAH/OPAH pollution and the repressed Treg cell function, as coal and biomass use was not regulated in Lintao but was stringently restricted in Lanzhou.

### **P03.2140. Personal and Area Monitoring of Particulate Matter in an Informal Electronic Waste Recycling Site: A Preliminary Study**

Lawrencia Kwarteng

*Lawrencia Kwarteng<sup>1</sup>, John Arko-Mensah<sup>1</sup>, Stuart Batterman<sup>2</sup>, Thomas Robins<sup>2</sup>, Julius Fobil<sup>1</sup>*

- 1. Biol. Env'tal & Occupational Health Sciences, University of Ghana, Accra, Ghana, Ghana.*
- 2. Environmental Health Sciences, UMICH'S SCH OF PUBLIC HEALTH, ANN ARBOR, MI, United States.*

**Abstract:** Background: E-waste recycling activities results in release of a mixture of pollutants, including Particulate Matter (PM) into the ambient environment. Exposure to PM could have deleterious health effects, mostly dependent on concentration and composition. A combination of area and personal monitoring is important in estimating both long and short term/acute exposures, important for health risk assessment. Objectives: The aim of this preliminary study is to assess exposure levels to PM among e-waste recyclers at Agbogbloshie, an informal e-waste recycling site through personal air monitoring and area monitoring. Methods: This study is part of the ongoing West Africa GEOHealth II study. Nine e-waste workers (five burners and 4 dismantlers) were selected in October for the study. Each participant undertook a one-time personal air monitoring for four hours by wearing a back pack containing a real time monitor, Met One Aerocet 831 which measured PM<sub>1</sub>, PM<sub>2.5</sub>, PM<sub>4</sub>, PM<sub>10</sub>, and TSP every minute. Simultaneously, onsite area monitoring was also done. Pearson correlation was used to determine the relationship between PM measured in personal and area monitoring. Results: Overall, burners recorded higher mean PM concentrations, PM<sub>1</sub>, PM<sub>2.5</sub>, PM<sub>4</sub>, PM<sub>10</sub>, and TSP (41.20±5.98, 74.89±15.54, 122.90±37.77, 215.86±106.6 and 293.15±160.93) compared to dismantlers (34.36±3.67, 54.81±7.13, 81.86±10.88, 128.35±26.33, and 169.64±42.40). There was a positive correlation between average personal and area PM and TSP values ( $r = 0.994$ ) Conclusion: Ewaste activities results in the release of high levels of PM and TSP which could have negative implications on respiratory health of ewaste workers.

### **P03.2160. Early Detection of Severe Dengue Infection in the Emergency Department: An Epidemiological Approach**

How-Ran Guo

*Tzu-Ching Sung<sup>1</sup>, Hsin-I Shih<sup>2</sup>, Hsiang-Chin Hsu<sup>2</sup>, How-Ran Guo<sup>3</sup>*

*2. Department of Emergency Medicine, National Cheng Kung University Hospital, National Cheng Kung University, Tainan, Taiwan.*

*3. Department of Environmental and Occupational Health, College of Medicine, National Cheng Kung University, Tainan, Taiwan.*

**Abstract: Objectives.** We develop an epidemiological approach to determine the emergency patients at high risk of severe dengue (SD), known as hemorrhagic fever (DHF) or dengue shock syndrome (DSS), and to facilitate timely appropriate medical treatment reducing the number of complications and death by the scoring system. **Methods.** This retrospective study was conducted during 2015 dengue outbreak in southern Taiwan. An efficient scoring system has been created to differentiate SD by clinical and laboratory features. Type A was defined as cases who were less than 65 years of age, and have none of the dengue related underlying diseases (DM, CKD or ESRD, liver cirrhosis, COPD, CHF, and neoplasm) according the WHO guidelines. Type B were those aged 65 years and older, and with any of the dengue-related underlying diseases. Significant coefficients of parameters were transformed into SD scores and constructed by division of each coefficient with the smallest coefficient of the multivariate logistic regression models by the backward stepwise selection. The accuracy and validity of SD scores are tested and predicted. **Results.** The severity scores ranged from 1 to 3, and the sum of total scores were 10. Significant parameters were used to construct possible SD models to distinguish a higher critical odds ratio when there was an underlying diseases [Adjusted OR, AOR (AOR: 22.68, 95% CI: 6.86-74.96)], tachypnea (AOR: 2.91, 95% CI: 1.29-6.56), shock (AOR: 15.52, 95% CI: 3.97-60.65-), and aPTT prolonged (AOR: 4.48, 95% CI: 2.05-9.78), and Hepatitis (AOR: 2.48, 95% CI: 1.07-5.74). An AUC of 0.82 was obtained which confirmed the good performance of the model. Positive likelihood ratio (LR+) of 10.74 indicates that the result greater than or equal to the severe score of 8 has a large effect on increasing the probability of SD presence. **Conclusions.** Our study has demonstrated an efficient scoring system to predict SD. The further validation of SD application should be confirmed.

**P03.2180. Factors and Developments Related to the Exposition (Direct and Indirect) of People to Mercury in Mines: A Systematic Review, 2005-2017**

Aanh Dimate Garcia

*Aanh E. Dimate Garcia<sup>1</sup>, Diana C. Rodriguez Romero<sup>1</sup>*

*1. Teacher of the faculty of health sciences, postgraduate health (epidemiology, health and safety at work, health audit), Fundación universitaria del área andina, Bogota, Cundinamarca, Colombia.*

Abstract: Mercury is a chemical called heavy metal, which is used in mining activities especially that related to the extraction of gold by people who work in this trade, presented in them affectations in their health by having direct and indirect contact with this chemical. Objective: to identify risk factors for people associated with direct and indirect contact with mercury within the mining activity. Methods: systematic review following the statement PRISMA, is directed with the direct and indirect contact of mercury and its effects on health, was based on data such as Pubmed, Science Direct, Scielo, Cochrane and Lilac. Results: The main findings of the present review showed that most of the factors and outcomes related to exposure (direct and indirect) develop over time and are caused by work in mines or by the environment (surrounding population). Conclusions: The different authors agree that exposure to mercury directly or indirectly has harmful effects on human and environmental health, however, further studies should be conducted to take more significant measures to mitigate the effects of mercury on humans and the environment. Keywords: Mercury, mining workers, effects in the health, factors of risk. Keywords: Mercury, mining workers, effects in the health, factors of risk

**P03.2190. Health Risks Associated to Vulnerability of Water and Sanitation System in a West African Medium-Sized City: A Spatial Epidemiological Approach**

Sokhna Thiam

*Sokhna Thiam*<sup>1</sup>

*1. Epidemiology and Public Health, Institut de Recherche en Santé, de Surveillance Epidémiologique et de Formations (IRESSEF), Dakar, Senegal.*

**Abstract:** Background: African cities are facing critical societal challenges linked to environmental and health changes. These changes are induced by urbanization dynamics with limited urban development governance and basic services delivery. Using environmental, epidemiological and spatial indicators, this study aims to assess the impact of Mbour's social-ecological system on diarrhoeal diseases transmission with particular emphasis on vulnerability to environmental health risks according to water and sanitation status. Methods: A multidisciplinary survey was undertaken in 2016 in Mbour, Senegal, targeted 800 households. Statistical and spatial methods were used to address environmental health challenges and health risks distribution and inequalities in the city. Results: The findings from the household survey showed an insufficiency in clean water access, hygiene and sanitary systems in Mbour that foster diarrhoea transmission pathways. It showed that 58% of the surveyed household are connected to water networks with significant disparities between localities; and 72% of the household empty their wastewater in the street. Diarrhoea morbidity (33%) was higher in the neighbourhoods with the largest number of contaminated drinking water especially in the most densely populated neighbourhoods of the city. Mapping revealed that diarrhoea risk is spatially variable in accordance to environmental sanitation disparities. Conclusion: The dynamic of socio-ecological system demonstrated that environmental factors linked to unimproved drinking water sources and sanitation services were the main driver of diarrhoea transmission in the city. The linkage between health risks due to diarrhoea and environmental conditions addresses the issues of the Sustainable Development Goals (SDGs), especially the SDG 3 and 6 respectively on Health, Water and Sanitation. This calls for more research to contribute to more efficient urban health policies in Mbour context and in other cities across Africa.

**P03.2200. Impact on Health and Environment from the Viewpoint of the Families Affected by the Installation of the Foz Do Chapecó Hydroelectric Power Plant in the State of Santa Catarina, Brazil**

Maria Busato

*Maria A. Busato<sup>1</sup>, Lisiane Rosa<sup>1</sup>, Simone C. Nothaft<sup>1</sup>*

*1. Area Ciências da Saúde, Community University Chapecó Region, Chapecó, SC, Brazil.*

**Abstract:** Objective To analyze the impact on health and environment from the perspective of families affected by the installation of the Foz do Chapecó Hydroelectric Power Plant in the state of Santa Catarina/Brazil. Method This was study conducted with 13 farming families affected by the reservoir of the power plant, whose data were collected through interviews. The analysis was based on the methodology of thematic analysis with the construction of categories. Results The analytical categories were: "Social and environmental changes experienced by families" and "The impacts on health resulting from the change of the environment". The effect on human health due to the environmental changes caused by the hydroelectric power plant may have physical or mental nature, which is reflected in feelings of insecurities that should be considered as a risk to trigger health problems and changes in the quality of life of this population. It was observed that the surveyed families were very linked to the place where they lived, and that the departure from their places of origin entailed cultural losses and social disruptions. They left strong feelings of distress and insecurity about the future. Some of them express the feeling of discomfort with the houses and working conditions found in the new place where they started to live. Regarding the environment, the surveyed families recognize that there has been a big change with alterations in flora and weather. They also highlighted that the change of the natural environment produced impacts on human health that are mainly manifested in the form of diseases such as depression, hypertension, insomnia and alcoholism. Conclusion the change of the environment with the installation of a hydroelectric power plant entailed social, economic, environmental and health impacts to the affected population. The different sectors involved in the licensing process should adopt new ways of assessing impacts at the time of implementation of this type of enterprise.

### **P03.2210. Shale Gas Activity and Increased Rates of Sexually Transmitted Infections in Ohio, 2000-2016**

Elise Elliott

*Nicole Deziel<sup>1</sup>, Zoe Humeau<sup>2</sup>, Elise Elliott<sup>1</sup>, Joshua Warren<sup>3</sup>, Linda Niccolai<sup>4</sup>*

*4. Epidemiology of Microbial Disease, Yale School of Public Health, New Haven, CT, United States.*

**Abstract:** Background: The shale gas ("fracking") industry depends on a mobile workforce, whose influx could have social impacts on host communities. Sexually transmitted infections (STIs) can increase through sexual mixing patterns associated with labor migration. No prior studies have quantified the relationship between shale gas activity and rates of three reportable STIs: chlamydia, gonorrhea, and syphilis. Methods: We conducted a longitudinal, ecologic study from 2000-2016 in Ohio, situated in a prolific shale gas region in the United States (US). Data on reported cases of chlamydia, gonorrhea, and syphilis by county and year were obtained from the Ohio Department of Health. All 88 counties were classified as none, low, and high shale gas activity in each year, using data from the Ohio Department of Natural Resources. Annual rate ratios (RR) and 95% confidence intervals (95% CIs) were calculated from mixed-effects Poisson regression models evaluating the relationship between shale gas activity and reported annual STI rates while adjusting for secular trends and potential confounders obtained from the US Census. Results: Compared to counties with no shale gas activity, counties with high activity had 21% (RR=1.21; 95%CI=1.08-1.36) increased rates of chlamydia and 19% (RR=1.19; 95%CI=0.98-1.44) increased rates of gonorrhea, respectively. No association was observed for syphilis. Conclusion: This first report of a link between shale gas activity and increased rates of both chlamydia and gonorrhea may inform local policies and community health efforts.

### **P03.2220. Drinking Water Salinity Categories and Lower Blood Pressure: Evidence from Coastal Bangladesh**

**Abstract:** Background: The goal of this study is to assess how electrical conductivity (EC), an aggregate measure of all minerals in water, is associated with blood pressure in southwest coastal Bangladesh. Method: This analysis included 1,574 persons from 708 households participating in drinking water salinity reduction studies in southwest coastal Bangladesh in 2016-2017. We used multilevel regression models to estimate differences in mean systolic blood pressure (SBP) and diastolic blood pressure (DBP) across water salinity categories defined by the Food and Agricultural Organization of the United Nations: freshwater (electrical conductivity < 0.7 mS/cm), mild saline (EC ≥ 0.7 and < 2 mS/cm), and moderately saline (EC ≥ 2 and <10 mS/cm). EC was measured by Hanna Salinity™ meter. Models included participant-, household-, and community-level random intercepts and were adjusted for age, sex, body mass index, physical activity, smoking status, and household wealth. We also considered associations of EC with 24-hour urine biomarkers of Na, K, Ca and Mg intake using linear or parametric quantile regression models with the same adjustments and random effects. Missing data were handled by multiple imputations with chained equations. All results are reported with cluster-robust standard errors. Results: Drinkers of moderately saline water had 1.66 [95% confidence interval (CI): 0.13, 3.19] mm Hg lower mean SBP and 1.30 [95% CI: 0.46, 2.13] mm Hg lower mean DBP compared to freshwater drinkers in adjusted models. Drinkers of moderately saline water had 17.50 [95% CI: 12.54, 22.45] mmol/day higher mean urinary Na, 0.32 [95% CI: -1.59, 2.23] mmol/day higher mean K, 1.24 [95% CI: 1.08, 1.41] times higher median daily urinary Ca, and 1.27 [95% CI: 1.10, 1.47] times higher median daily Mg compared to drinkers of fresh water in adjusted models. Conclusion: Higher drinking water salinity was associated with lower blood pressure, perhaps due to higher levels of salubrious minerals.

**P03.2230. A Critical Analysis of a Community-Based-Participatory Study in Environmental Health: Methodology, Results and Perspectives for Local and National French Stake-Holders.**

Mélina Le Barbier

*Florence Kermarec<sup>1</sup>, Jean-Luc Lassalle<sup>1</sup>, Christophe Bonaldi<sup>1</sup>, Pascal Empereur-Bissonnet<sup>1</sup>, Christophe Perrey<sup>1</sup>, Abdelkrim Zeghnoun<sup>1</sup>, Mélina Le Barbier<sup>1</sup>*

*1. Santé Publique France, Saint Maurice, France.*

**Abstract:** Community-based-participatory study in environmental health is relatively rare in Europe. Santé publique France (the French National Public Health agency) was commissioned by a local health authority to analyze the method implemented in a Franco-American participatory survey in industrial port zone of Marseille, and the subsequent results on the impact of industrial exposures on the population's health. To respond to this referral, Santé publique France set up an interdisciplinary support committee. The committee considered that the existence of risk excesses for several diseases reported in the study and their extent were limited by selection biases of the sample surveyed, the selected references, and the adjustment methods used. Despite methodological limits, the results presented confirmed that this territory requires a great level of attention from the public authorities. Committee also highlighted that the community-based epidemiological approach, based on people's perceptions and experience, seems to complement the approach of traditional epidemiology. As in many other industrial sites, community members of this zone have to deal with industrial and economical tool preservation and also sanitary effects of environmental pollution generated by these activities. In order to properly identify and manage the situation and to implement effective health risk prevention measures, it is necessary to take into account the entire territory, its stake-holders and its socio-economic history. We propose to expose and discuss results, conclusions and perspectives of this critical analysis. We will also expose methodology of this interdisciplinary critical analysis and how the community-based-participatory dynamic was considered by local stake-holders in a complex political and cultural context.

### **P03.2240. Potential Role of the Growth and Empowerment Measure to Enhance Environmental Health Research and Interventions**

Abstract: The often-overlooked ability to protect and restore lost psychosocial wellbeing and mental health in the face of increasing environmental stress, dwindling capacity to meet basic needs and climate change is arguably one of our greatest health challenges. Poor mental health is already a leading contributor to the global burden of disability and reduces human capacity for collective planning and innovating, responding to crises and recovering from disasters and losses. Multiple environmental distresses, from water and food insecurity to climate change, place enormous pressure on people's ability to feel in control, see meaning and purposes in their lives and stay connected to one another in increasingly desperate circumstances. This situation is familiar to Aboriginal Australians, who have endured systematic disempowerment of their culture and families and dispossession of their Lands, waters and governance by Europeans since 1788. Although huge health inequalities remain between Aboriginal and non-Indigenous Australians, Aboriginal people have made remarkable contributions to Australian society and health research - especially towards understanding healing and empowerment. This presentation will argue the relevance of empowerment to address global and local environmental health challenges. We will introduce the Australian Aboriginal-informed tool, the Growth and Empowerment Measure [GEM], which measures complex psychosocial domains, e.g. identity, healing from painful feelings, creating safety, self-efficacy, voice, spirituality and community strength. Confirmatory Factor Analysis has demonstrated GEM's cross-cultural validity and measurement invariance (Indigenous and non-Indigenous). We will discuss its potential contribution to environmental epidemiology, eg identifying community empowerment needs, health impact assessment (especially of developments that threaten fundamental environmental values) and evaluation of environmental health interventions.

### **P03.2250. Exposures to Urban Wildlife and Ectoparasitic Insects among Homeless Persons in Boston, MA**

Jessica Leibler

*Jessica Leibler<sup>2</sup>, Kelsey Robb<sup>1</sup>, Eugene Joh<sup>2</sup>, Jessie Gaeta<sup>4</sup>, Marieke Rosenbaum<sup>3</sup>*

- 1. Epidemiology, Boston University School of Public Health, Boston, MA, United States.*
- 2. Environmental Health, Boston University School of Public Health, Boston, MA, United States.*
- 3. Public Health and Community Medicine, Tufts University Cummings School of Veterinary Medicine, Grafton, MA, United States.*
- 4. Boston Health Care for the Homeless Program, Boston, MA, United States.*

Abstract: Urban homeless persons in the United States spend extended periods of time outdoors and may live in crowded conditions with poor hygiene. These settings may increase exposure to animal and insect vectors of disease, including wild rodents, feral cats, wild birds, lice, fleas, and ticks. Despite these risks, assessments of the frequency and risk factors for zoonotic and vector-borne infections among homeless people are limited. To address frequency of exposure to potential sources of zoonotic and vector-borne disease, we queried a cross-sectional sample of patients served by Boston Health Care for the Homeless Program's primary care facility (n=194) as to their sightings of urban wildlife and experiences with ectoparasitic insects. Nearly thirty percent of participants reported daily rodent sightings, and 25% reported daily sightings of cats. Body lice and fleas were reported by 4% and 11% of participants, respectively. Individuals who slept outdoors had more than 13 times the odds of greater frequency of rodent sightings in the last three months compared with those who did not sleep on the street (OR: 13.3; p=0.001; 95% CI: 2.7, 65.3). Heavy drinking was significantly associated with greater frequency of sightings of rodents (OR: 2.5 (1.0, 6.4); p=0.05), cats (4.5 (1.8, 11.5); p=0.002) and dead birds (3.3 (1.4, 7.9); p=0.007). Heavy drinking was also positively associated with ever-experiencing a parasite infestation during periods of homelessness (p=0.03). Frequent sightings of rodents and rodent feces by homeless people in particular may indicate human exposure risk to urban rodent-borne pathogens, including *Leptospira* spp, Seoul hantavirus, and *Rickettsia akari*. Exposure to cats suggests that *Bartonella henselae* infection in homeless persons is worthy of investigation. These infections may be underreported or misdiagnosed in this population. Studies of zoonotic and vector-borne infections among persons experiencing homelessness are warranted.

### **P03.2260. Urinary Chromium and Dyslipidemias: A Cohort Study of Urban Adults in China**

Lili Xiao

*Lili Xiao<sup>1</sup>, Yun Zhou<sup>1</sup>, Jixuan Ma<sup>1</sup>, Chunmei Zhu<sup>1</sup>, Shijie Yang<sup>1</sup>, Limin Cao<sup>1</sup>, Bin Wang<sup>1</sup>, Jing Yuan<sup>1</sup>, Weihong Chen<sup>1</sup>*

*1. Department of Occupational & Environmental Health, School of Public Health, Huazhong University of Science and Technology, Wuhan, Hubei, China.*

**Abstract:** Abstract Background: Chromium is recognized as a nutritional enhancer and necessary for normal carbohydrate and lipid metabolism. However, the health effects of chromium exposure on lipoprotein metabolism have not been well evaluated. Objective: To investigate the cross-sectional and longitudinal effects of urinary chromium concentration on lipids levels or risk of dyslipidemias in a general Chinese population from the Wuhan-Zhuhai cohort study. Methods and Results: Serum lipids levels and urinary chromium concentration were measured at baseline and follow-up. Associations of urinary chromium concentration with lipids levels or risk of dyslipidemias were analyzed by generalized linear and binary logistic regression models, respectively. We found significant associations of increased urinary chromium concentration with reduced serum triglycerides (TG) level and elevated high-density lipoprotein cholesterol (HDL-C) level at baseline and follow-up. With adjustment for covariates, each one-unit increase in log-transformed urinary chromium concentration was associated with a 0.25 mmol/L decline in TG, and a 0.05 mmol/L ascend in HDL-C (all  $P < 0.05$ ). Downward trends of dyslipidemias (hyperTG and hypoHDL-C) were significantly associated with increasing quartiles of urinary chromium concentration (all  $P$  trend  $< 0.05$ ). Our results also suggested that urinary chromium levels were associated with coarse grain intake in both male and female participants. Conclusion: This study provides evidence that elevated urinary chromium concentration was associated with decreased risk of dyslipidemias in a general Chinese population. These findings warrant replication in other studies with adequate sample sizes.

### **P03.2270. Changes in Activities of Daily Living in Aging Congenital Minamata Disease Patients**

Takashi Yorifuji

*Takashi Yorifuji<sup>1</sup>, Shigeru Takaoka<sup>3</sup>, Philippe Grandjean<sup>2</sup>*

*1. Department of Human Ecology, Graduate School of Environmental and Life Science, Okayama University, Okayama, Japan.*

*2. Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, MA, United States.*

*3. Minamata Kyoritsu Hospital, Minamata, Japan.*

Abstract: Severe methylmercury poisoning occurred in Minamata and neighboring communities in Japan during the 1950s and 1960s. A considerable number of children were born with conditions resembling cerebral palsy, later known as congenital Minamata disease. Although these children are now in their 50s or 60s, assessments measuring changes in activities of daily living (ADL) have not been performed as they age. We therefore assessed the changes in ADL status of surviving patients. We recruited a total of 11 congenital Minamata disease patients and obtained the patients' ADL status approximately 10 years previously from their caregivers or from hospital records. For comparison, we assessed the current values of the two ADL measures [Barthel Index (BI) and Functional Independence Measure (FIM)]. We compared the current and previous ADL status of the patients using Wilcoxon signed-rank test. Both ADL measures, including the status related with cognition, had significantly declined during the 10 years. The same was true for the BI score ( $p=0.01$ ). Similarly, all functions of the FIM scores declined (i.e., self-care, sphincter control, mobility, locomotion, communication, and social cognition), and for FIM physical and cognition subscores as well as FIM total score, the declines were statistically significant. The present study indicates that the ADL status of the congenital Minamata disease patients in their 50s or 60s declined significantly during a time interval of about 10 years, a decline that was fairly steep in comparison with expectation in subjects of similar ages. While already incapacitated due to the prenatal methylmercury poisoning, their accelerated ageing suggests that patients with developmental neurotoxicity have less reserve capacity to compensate for normal ageing. These patients need continuous and intense medical and welfare support in the community.

**P03.2290. Association between Urinary Metal Levels and Chronic Kidney Disease in Residents Living near to a Big Petrochemical Complex**

Tzu-Hsuen Yuan

*Tzu-Hsuen Yuan<sup>1</sup>, Ming-Jie Jhuang<sup>1</sup>, Chang-Chuan Chan<sup>1</sup>*

*1. College of Public Health, National Taiwan University, Institute of Occupational Medicine and Industrial Hygiene, Taipei, Taiwan.*

**Abstract:** Background/Aim Previous studies showed that exposure to heavy metals was associated with alteration of kidney function, and burning fossil fuels and petrochemicals may release metal pollutants. We conduct a study to investigate whether the kidney functions are decreased for residents living in the vicinity of a petrochemical complex. Methods We recruited 1,374 aged above 35 years in 2014-2016 who lived in Dacheng township, which is near the largest complex in central Taiwan. The subjects were classified into adult and elderly by a cut-off age 65 years. Two Chronic kidney disease (CKD) indicators were as potential outcomes of exposure: (1) eGFR calculated through the equations of Chronic Kidney Disease Epidemiology Collaboration; (2) CKD defined as eGFR lower than 60 ml/min/1.73m<sup>2</sup>. We conduct linear and logistic regression to investigate the association between the exposure and CKD. The regression models were adjusted for adjusted for gender, body mass index, smoking habits, and diabetes. Results Our 1,374 study population were classified into 689 adults and 685 elderly with mean age of 51.1 years and 73.3 year, respectively. Among the 689 adults, 11%, 9% had diabetes, CKD; and the mean eGFR was 70.8 ml/min/1.73m<sup>2</sup>. Among the 685 elderly, 17%, 38% had diabetes, CKD; and the mean eGFR was 62.7 ml/min/1.73m<sup>2</sup>. Urinary nickel, vanadium, chromium, arsenic and cadmium levels increased as the distance to the petrochemical complex decrease. A decreased eGFR was associated with urinary nickel, vanadium, chromium and distance to Complex in adults and elderly; and urinary arsenic and cadmium only in adult. An increased CKD was associated with distance to Complex in adults and elderly; and urinary nickel, vanadium and chromium only in elderly. Conclusions We concluded that exposure to heavy metals were associated with decreased renal function and increased risks of CKD in the adults or the elderly living in the vicinity of a petrochemical complex.

### **P03.2300. The Correlation between Pesticide Exposure and Health Effects among Tobacco Farmers, Northern, Thailand**

Saowanee Norkaew

*Saowanee Norkaew<sup>1</sup>, Sarunya Punkhun<sup>3</sup>, Nutta Taneepanichsku<sup>2</sup>*

- 1. Faculty of Public Health, Thammasat University, Pathumthani, Pathumthani, Thailand.*
- 2. College of Public Health Sciences, Chulalongkorn University, Bangkok, Bangkok, Thailand.*
- 3. Department of Disease Control, Ministry of Public Health, Bangkok, Bangkok, Thailand.*

Abstract: Tobacco farm is one of the crops using load of pesticides, especially Organophosphates pesticides. Enzymes cholinesterase has been used to monitor the extent of organophosphate and carbamates exposure in tobacco farmers. The objective of this cross-sectional descriptive study was to investigate the correlation between pesticide exposure and health effects among tobacco farmers, Northern, Thailand. A questionnaire and blood enzymes erythrocyte cholinesterase test was completed by face to face from 44 tobacco farmers in 2016-2017. Data were analyzed using descriptive statistics and Chi-Square test and Fisher's exact test. The results showed that the most of the participants were female (75.0%), age between 51-60 years (54.5%) and educational levels in primary school (79.5%). It was found that the prevalence of unsafe level of enzymes cholinesterase was 90.9%. Most tobacco farmers mentioned their health symptoms were excessive sweating (47.7%), irritation of the throat and restlessness (34.1%). Some of them reported the running nose and muscle cramp (29.5%). Association between health symptoms and blood enzymes erythrocyte cholinesterase test was shown that; most of the unsafe level of enzyme cholinesterase reported sweating (47.5%). Follow by irritation of the throat (37.5%) and muscle cramp (35.0%). The results can be used as a database for blood enzymes erythrocyte cholinesterase levels. This research suggested that public health education training programs including knowledge regarding to pesticides use and exposure, appropriate personal protective equipment (PPE) for tobacco farmers to improve their ability to handle pesticide and quality of life.

**P03.2310. Estimating of the Costs of Occupational Injuries and Illnesses from Agricultural Work in Thailand**

Densak Yogyorn

*Densak Yogyorn<sup>1</sup>*

*1. Occupational Health and Safety, Mahidol University, Bangkok, Thailand.*

Abstract: Injured workers in agricultural sector in Thailand were absented in workers' compensation system as they have long been excluded from labor department's database. Due to Lack of neither record of injured workers nor cost of injuries and illnesses in Agricultural works, therefore no interest to decision makers in the governmental authority to do anything to address this issue. This study propose an alternative method to analyze the costs of occupational injuries and illnesses by estimating monetary values of lost productivity allocation based on injury or illness related production function and the output of agricultural commodities.

### **P03.2320. Chronic Diseases in Agricultural Workers with Different Pesticide Exposure in Mauco, Chile**

Sandra Cortes

*Sandra Cortes<sup>1</sup>, Claudia Foerster<sup>2</sup>, Viviana Orena<sup>3</sup>, Catterina Ferreccio<sup>1</sup>*

- 1. Salud Publica, Pontificia Universidad Católica de Chile-ACCDIS, Santiago, Santiago, Chile.*
- 2. Instituto de Ciencias Agronómicas y Veterinarias, , Universidad de O'Higgins, Rancagua, Chile.*
- 3. Facultad de Ciencias, Universidad Mayor, Temuco, Chile.*

**Abstract:** Introduction the Maule Cohort (MAUCO) is a population-based cohort in an agricultural county in central- southern Chile. The prevalence of chronic diseases and risk factors among agricultural workers (AW) from MAUCO were examined in accordance to different levels of exposure to pesticides. Methods People aged 38 to 74 were eligible. All participants answered an epidemiological survey, received standard medical evaluations, and answered information on the use of pesticides. We compared prevalence of chronic conditions and risk factors among AW no pesticide applicators (n=1527) and AW pesticide applicators (n=875). We considered as control groups all workers on any activity other than agriculture (n=2,287). Results Among 4,689 AW identified in MAUCO, 51% were men; 18.7% reported direct exposure to pesticides as applicators (32% of men and 4.7% of woman). 64% had less than 8 years of schooling. Among men, the prevalence of binge drinking and overweight were higher among male applicators (45.2% and 25.9%) than in the control group (40.8%; 31.7%). 56.4% of male applicators had been exposed to pesticide for more than 10 years and only 15.5% reported use of personal protective equipment (vs control group both were 0%). Medical diagnoses of hypertension, diabetes and cancer were lower among applicators. A respective risk of 21.8%, 10.7%, and 4.3% were recorded for male applicators vs 23.2%, 13,8%, and 5.4% in males AW not exposed to pesticides. In male, only respiratory disease is higher in applicators (4.3%) than AW no exposed (2.9%). OR and IC 95%, adjusted by age were: hypertension 0.8 (0.7-1.2), diabetes 0.7(0.5-1.02), cancer 0,7 (0.3-0.8), and respiratory disease 1.5 (0.8-2.9). Conclusions Even though, applicators had more risk factors, they had lower prevalence of chronic condition than non-agricultural workers. Nevertheless, the difference did not reach statistical significance. Further analysis is need to explore the healthy workers bias in our participants.

### **P03.2330. Mitochondrial DNA Damage in Spermatozoa of Faroese Men Exposed to Organochlorines**

Laura Neumann

*Laura Neumann<sup>1</sup>, Matias Attene-Ramos<sup>1</sup>, Pal Weihe<sup>2</sup>, Philippe Grandjean<sup>3</sup>, Melissa J. Perry<sup>1</sup>*

*2. Department of Occupational Medicine and Public Health, Faroese Hospital System, Tórshavn, Faroe Islands.*

*3. Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, MA, United States.*

Abstract: Mitochondria are essential for sperm function and fertility, serving such functions as cellular energy for motility, apoptosis during spermatogenesis and capacitation. Interest in mitochondria has increased in epidemiologic studies but there has been no focus on sperm so far. Few mechanisms have been explored why sperm counts have been declining over the last 40 years. We sought to demonstrate the relationship between mitochondrial DNA and sperm health. This pilot study used mitochondrial DNA damage and copy number to assess negative effects of exposure to organochlorines on sperm. Semen and serum samples from men (n=50) 22-44 years old who participated in Faroe Islands health studies were randomly selected from the first and third tertiles (n=25 for each tertile) of serum concentrations p,p'-DDE and PCB congeners 118, 138, 153, and 180 (adjusted for total lipids). Mitochondrial DNA damage was determined using QPCR that measures the decrease in DNA amplification due to the presence of DNA lesions that stalls the progression of DNA polymerase. Validated primers that amplify a long sequence were used to increase the probability that a DNA lesion will be present. The average mtDNA copy number of per sperm cell in each sample was measured using previously published primers. Amplification progress was followed using cyber green dye and amplification specificity was controlled by using temperature melting curves. Mitochondrial DNA content was calculated using the difference in cycle thresholds between nuclear and mitochondrial DNA. Multivariate adjusted Poisson models were used to estimate the relationship between organochlorine exposure and DNA damage. Age, abstinence time, smoking status, were all potential confounders controlled for in the adjusted analysis. Incidence rate ratios (IRRs) and 95% confidence intervals were calculated for each model. We expect to see an increase in mitochondrial DNA damage in sperm of men with higher exposures to p,p'-DDE and PCBs.

### **P03.2340. Urinary Inorganic Arsenic Concentration and Type 2 Diabetes Mellitus and Hypertension Development: A Population-Based Analysis in Arica, Chile**

Maria Munoz

*Maria P. Munoz<sup>1</sup>, Paola A. Rubilar<sup>1</sup>, Macarena Valdes<sup>1</sup>, Andrea Gomez<sup>1</sup>, Marta Saavedra<sup>2</sup>, Veronica Iglesias<sup>1</sup>*

- 2. SEREMI Salud Arica y Parinacota, Arica, Chile.*

**Abstract:** Introduction: Studies that evaluated the association between type 2 diabetes mellitus and hypertension has been consistent in population exposed to high levels of arsenic. However, the evidence is no clear regarding low levels of exposure. The aim of this study was to explore the association between the concentration of inorganic arsenic in urine and the development of type 2 diabetes mellitus and hypertension. Methods: Data analysis of 10.340 individuals over the age of 14, of the population register of people exposed to polymetals, evaluated between 2009 and 2015. Outcome variable: Self-report of diagnosis of type 2 diabetes mellitus (T2DM) and hypertension (HBP). Exposure variable: Concentration of inorganic arsenic in urine. To evaluate association, we used multiple logistic regression models adjusted for creatinine, age, and body mass index. Results: Average age 40 years. The prevalence of diabetes was 8% (CI95% 0.073-0.085) and hypertension 15% (CI95% 0.143-0.159), (31% lost data). The median of inorganic arsenic was 18 µg/L (p25-p75 11-27 µg/L). The adjusted model showed a modest association between inorganic arsenic and T2DM (OR: 1.008, 95% CI 1.003-1.013). Regarding the relationship with HBP, the association was not significant (OR: 0.99, IC95% 0.993-1.004). Conclusion: The results support the hypothesis that low levels of arsenic exposure could be associated with T2DM; however, should be considered with caution due limitations as the way of measuring the outcome variable, the % of lost data and the lack of information from other confounding.

### **P03.2350. Effects of Early Life Arsenic Exposure on Renal Function in Adolescents and Young Adults in Rural Bangladesh**

*3. Arsenic Health Effects Research Group, University of California, Berkeley, Berkeley, CA, United States.*

**Abstract:** Background: Long term exposure to arsenic through drinking water has been reported to increase the risk of chronic kidney diseases in adults. However, information on the impact of early life arsenic exposure on renal function in adolescents is limited. This study evaluated kidney function in adolescents and young adults exposed to elevated level of inorganic arsenic in utero and in the first five years of life in rural Bangladesh. Methods: The study was conducted in rural Bangladesh, Matlab. A cohort of 200 adolescents and adults now aged 11-22 years were enrolled of which 107 were exposed to water arsenic concentration over 400µg/L during prenatal life and early childhood (exposed group) and 93 had a water concentrations of less than 10 µg/L (unexposed group). Renal function was assessed by the level of serum beta 2 microglobulin, a marker of early renal injury. Serum beta 2 microglobulin concentration was determined by the Immunoturbidimetric assay. Participants were categorized as having normal or elevated β2MG based on the age and sex specific reference values. Results: The mean age was 14.9± 2.8 years. In an adjusted model, exposed individuals had nearly 2-fold higher risk of elevated beta 2 microglobulin compared to the unexposed [odds ratio (OR) =1.98; 95% Confidence interval (CI): 1.12-3.49; 1-tailed p =0.010]. The effect was more pronounced in females (OR=3.02, 95% CI: 1.29-7.10; 1-tailed p=0.006) with little evidence in males (OR=1.36, 95% CI: 0.62-3.00; 1-tailed p =0.222). Conclusions: We found evidence of modest impairment of kidney function as indicated by elevated serum beta 2 microglobulin among the arsenic exposed individuals. Females showed greater evidence of arsenic induced renal injury. We plan to follow this cohort to assess the progression of changes in kidney function as they become older.

### **P03.2360. Arsenic in Drinking Water Interventions: Systematic Review of Community Based Approaches in Bangladesh**

Ondine von Ehrenstein

*Ondine von Ehrenstein<sup>1</sup>, Helene Riess<sup>1</sup>*

*1. UCLA, Los Angeles, CA, United States.*

**Abstract:** Background: Arsenic in drinking water remains a major public health concern in many countries with many millions exposed to concentrations magnitudes above the WHO recommended drinking water guideline. In spite of the wide scale acknowledgement of adverse effects on population health, millions of people in the affected regions continue to drink arsenic contaminated water. The purpose was to systematically review published studies on community/population based drinking water interventions to mitigate arsenic exposure. Methods: We systematically searched literature using the following data bases: Pub Med, Web of Science, and the World Health Organization Library, and grey literature. The inclusion criteria included: A population sample of at least 50 subjects, arsenic exposure via drinking water and reporting of arsenic concentrations, reported intervention. Findings: The search revealed over 4000 publications derived by our search terms. All titles were screened and if applicable the abstracts by 2 separate investigators. This resulted in inclusion of 82 publications that were further evaluated. Less than 20 of these publications involve community/population based interventions, and only 10 of the publications concerned low/middle income countries; these were mainly located in Bangladesh. Based on these findings, research gaps, and directions for further implementation research were identified. Interpretation: Arsenic in drinking water continues to be a threat to population health in many nations involving many millions of people globally affecting particularly lower income populations. In spite of a large body of evidence on the severe health effects related to arsenic, efforts to reduce population exposure via drinking water remain insufficient. Implementation research is needed to identify effective population based interventions and mitigation approaches to prevent arsenic exposure on a large scale.

**P03.2370. Geographic Variation and Contributions of Rurality and Area-Level Socioeconomic Circumstances to Incidence of Alzheimer's Disease over 11 Years: Multilevel Discrete-Time Event History Analysis of a Cohort of 261,669 Australians Aged 45 Years and Older**

Thomas Astell-Burt

*Thomas Astell-Burt<sup>1</sup>, Xiaoqi Feng<sup>1</sup>*

*1. Population Wellbeing and Environment Research Lab (PowerLab), Faculty of Social Sciences, University of Wollongong, Wollongong, NSW, Australia.*

**Abstract:** Background Longitudinal studies of environmental risk factors for Alzheimer's disease are scarce. Methods Data for this study comprised 261,669 participants in the Sax Institute's 45 and Up Study. Diagnoses of Alzheimer's disease were identified using the first recorded prescription of a cholinesterase inhibitor from recruitment to December 31st 2016, linked from the Pharmaceutical Benefits Scheme (provided by the Department of Human Services and part of Australia's universal health insurance). Participants with a cholinesterase inhibitor record prior to baseline were excluded. Multilevel discrete-time event history Poisson regressions (i.e. multilevel survival analysis) was used to measure geographic variation in Alzheimer's disease incidence and to assess contributions made by rurality and area-level socioeconomic disadvantage. Models were adjusted for age, gender and educational attainment. Results A total of 3,046 participants (1.16%) were diagnosed with Alzheimer's disease during the study. A median rate ratio of 1.48 indicated meaningful geographic variation. Alzheimer's disease risk was lower in more versus less disadvantaged areas (incidence rate ratio 0.85, 95% confidence interval 0.77 to 0.95) and in outer regional or remote areas compared to major cities (0.81, 0.67 to 0.97). Rurality and area-level disadvantage explained 3% of the geographic variation denoted by the median rate ratio. Gender did not modify these associations, nor were there differences in the association with area-level disadvantage by rurality. Conclusion Alzheimer's disease risk in this study is higher in more affluent, urban communities. Since the vast majority of the geographic variation was not explained by rurality or socioeconomic circumstances, other environmental factors warrant investigation.

### **P03.2400. Sex/Gender Differences in Cardiovascular Mortality Associated with Environmental Stressors: Systematic Review and Meta-Analysis**

Ute Kraus

*Ute Kraus<sup>1</sup>, Gabriele Bolte<sup>2</sup>, Malgorzata Debiak<sup>3</sup>, Katrin Groth<sup>3</sup>, Katharina Jacke<sup>4</sup>, Marike Kolossa-Gehring<sup>3</sup>, Sarah Nanninga<sup>2</sup>, Kerstin Palm<sup>4</sup>, Alexandra E. Schneider<sup>1</sup>*

- 2. University of Bremen, Bremen, Germany.*
- 3. German Environment Agency, Berlin, Germany.*
- 4. Humboldt-University of Berlin, Berlin, Germany.*

Abstract: Epidemiological studies of environmental stressors associated with cardiovascular health often show different effect estimates for males and females, but results are far from being consistent. Furthermore, there is a need to disentangle whether this modification is attributable to the biological sex, to gender including social role or cultural norms or an interplay of both. Our objective is to evaluate the current state of integrating sex/gender into environmental epidemiology and to quantify the sex/gender specific effects of ambient air pollution, air temperature and noise on cardiovascular mortality. We conducted a systematic literature search using the electronic databases PubMed and Web of Science (WOS). Publications in English or German between 2000 and 2017 which provide sex/gender specific effect estimates for short- and long-term associations between particulate matter with a diameter <2.5µm (PM2.5) and <10µm (PM10), nitrogen dioxide (NO2), ozone, air temperature as well as noise and cardiovascular mortality were screened. We will assess studies' integration of sex and gender with regard to conceptualization and operationalization of sex/gender, reporting of male and female specific baseline characteristics, exposure and health data as well as discussion of sex/gender specific results. After study quality rating sex/gender specific effects will be quantified by applying meta-analytic tools. Of 660 and 394 identified articles in PubMed and WOS, respectively, 76 studies met our inclusion criteria. Most studies dealt with PM2.5 (N=29), followed by PM10 (26), NO2 (26), air temperature (25) and Ozone (10). Only one study was found regarding noise. Preliminary results show that studies generally used a dichotomous category "male/female", lacked a clear conceptualization and therefore missed a gainful discussion of results. In the next steps we will continue with the extraction of necessary information and preparation of meta-analysis where possible.

### **P03.2410. Towards a Systematic Review of Environmental Injustice in Canada: National Patterns of Environmental Risks and Benefits**

Amanda Giang

*Amanda Giang<sup>1</sup>, Kaitlin Castellani<sup>1</sup>, David Boyd<sup>1</sup>*

*1. University of British Columbia, Vancouver, BC, Canada.*

Abstract: The environmental justice paradigm, now more than three decades old, is gaining new momentum by expanding to include a wider range of issues, broader geographic scope, and greater focus on potential solutions. However, to date, most research on environmental injustice in Canada has focused on specific case studies (e.g., large urban centres, Indigenous communities), with only a small number of studies focusing on national or regional-scale patterns. As part of a larger interdisciplinary effort, combining quantitative, qualitative, and legal analysis, this research will provide a deeper understanding of uniquely Canadian environmental injustice patterns and identify potential case studies for future work on the processes that create and perpetuate these injustices. In this preliminary analysis, we describe how exposure to selected environmental hazards (e.g., ground-level ozone, water advisories) and access to environmental benefits (e.g., green space) varies across demographic and socioeconomic characteristics in Canada, at a national-scale. We apply methodologies (described below) from recent national-scale analyses of NO<sub>2</sub> and fine particulate matter in the US and Canada to data from the 2016 census and existing environmental data sets from the Canadian Urban Environmental Health (CANUE) Research Consortium, and from federal and provincial governments. Population variables considered include Aboriginal and racialization status, immigrant status, socio-economic status, age, stratified by urban and rural residence. We compute descriptive statistics (Student's t-test and Cohen's d) to evaluate the significance and magnitude of differences between selected groupings. Finally, we situate these results within our larger framework for a systematic analysis of environmental injustice in Canada by discussing linkages to law, policy, and social movements that may contribute to, or remedy, these observed patterns.

### **P03.2420. Different Degrees of Environmental Contamination by Trace Metals from Mining Activities between DR Congo and Zambia in the African Copperbelt**

Célestin Banza Lubaba Nkulu

- 5. Division of Soil and Water Management, KU Leuven, Leuven, Belgium.*
- 6. Public Health and Primary Care, KU Leuven, Leuven, Belgium.*

**Abstract:** The African Copperbelt covers an area across the border between DR Congo and Zambia and has been a site of intense mining of copper and cobalt. To compare the environmental contamination by trace metals between the two countries, we sampled surface waters and various types of food crops (leafy vegetables, fruits, grains, roots and tubers) collected from kitchen gardens and fields in relevant locations in the (former) Katanga province in DR Congo (Kipushi, Likasi, Lubumbashi) and the Copperbelt Province in Zambia (Chingola, Kitwe, Luansha). The vegetables samples were rinsed with water, oven-dried at 70°C for 24 hours, crushed, and destroyed in ultrapure nitric acid. Trace metals were quantified by Inductively Coupled Plasma Optical Emission Spectrometry. Median (IQR) concentrations ( $\mu\text{g/L}$ ) of Mn [80 (18-2220) vs 13 (8-43)], Co [80 (22-2346) vs 2 (0.8-8.6)], Cu [138 (28-3206) vs 5 (1-18)], As [2 (0.5-20) vs 0.2 (0.1-0.2)], Cd [0.4 (0.1-5.7) vs 0.01 (0.00-0.02)], Pb [14 (2-311) vs 0.1 (0.0-0.7)], U [0.68 (0.14-3.12) vs 0.03 (0.00-0.17)] were 6 to 178 times higher in DRC (n=37) than in Zambia (n=42). In food stuffs, median concentrations (mg/kg) of Co [6 (2-16) vs 1.5 (0.8-3.0)], Cu [62 (25-166) vs 34 (20-55)], Cd [0.9 (0.3-2.3) vs 0.2 (0.1-0.4)], Pb [1.1 (3.9-10.4) vs 0.5 (0.2-1.0)], U [3.1 (1.5-5.8) vs 1.9 (0.9-3.7)] were 1.7 to 5.4 times higher in DR Congo (n=145) than in Zambia (n=135). The differences in trace metal contamination of food intended for human consumption between the two neighbouring provinces located in the same mining area of the African Copperbelt indicate that environmental pollution by mining activities is higher in DR Congo than in Zambia. The exact causes for this situation remain to be elucidated but increased efforts are needed to uphold and enforce environmental legislation and protect human health in DR Congo.

**P03.2430. Effects of Mothers' Language and Culture Backgrounds on Developmental Delays: A Nationwide Study on Children Born to Immigrant Mothers in Taiwan**

How-Ran Guo

*Yen-Cheng Tseng<sup>1</sup>, Der-Chung Lai<sup>3</sup>, How-Ran Guo<sup>2</sup>*

*2. Department of Environmental and Occupational Health, National Cheng Kung University, Tainan, Taiwan.*

*3. Department of Physical Medicine and Rehabilitation, Ditmanson Medical Foundation Chia-Yi Christian Hospital, Chia-Yi, Taiwan.*

Abstract: Transnational marriages are common as a result of globalization, and immigrant mothers face various degrees of differences in language and culture backgrounds. A mother has a large influence on the development of her children, but the effects of immigrant mothers' language and culture backgrounds on developmental delays (DD) of children are seldom studied. To evaluate the potential effects, we analyzed data from the national registry of DD in Taiwan from 2010 to 2013 and compared the incidence of DD in young children born to mothers from China, Vietnam, and Indonesia, where most of the immigrant mothers in Taiwan come from. We included 4604 new cases of DD in children under 7 years of age born to immigrant mothers during the study period. The incidence rates showed an increasing trend among children born to mothers from China, Vietnam, and Indonesia ( $p < 0.01$  in all years). Using Vietnam as the reference, we found the incidence rate ratios in children born to mothers from China ranged from 0.65 to 0.73, and those in children born to mothers from Indonesia ranged from 1.04 to 1.26. The findings support the important role of mothers' language and culture backgrounds in the development of children.

**P03.2450. Prevalence of Asthma-Related Symptoms in Adolescents Living near Industrial Animal Feeding Operations in Eastern North Carolina (U.S.A.)**

Virginia Guidry

*Virginia Guidry<sup>2</sup>, Alan C. Kinlaw<sup>1</sup>, Devon Hall<sup>3</sup>, Christine L. Gray<sup>1</sup>*

*1. University of North Carolina at Chapel Hill, Chapel Hill, NC, United States.*

*2. Office of Communications and Public Liaison, National Institute of Environmental Health Sciences, Durham, NC, United States.*

*3. Rural Empowerment Association for Community Help, Warsaw, NC, United States.*

Abstract: Animal feeding operations (AFOs) generate substantial air pollution; proximity has been associated with asthma-related illness in children. In North Carolina, swine and poultry AFOs are most common. We examined the relation between adolescents' home exposure to swine and poultry AFO-related air pollution and prevalence of asthma-related symptoms. The Rural Air Pollutants and Children's Health study enrolled 340 students from three eastern North Carolina middle schools in 2009. Participants self-reported demographics, health, and respiratory symptoms. We developed novel exposure indices to estimate home exposure to air pollution from swine and poultry AFOs. Home exposures were indexed by geocoded address, orthoimagery-derived size and location of barns within 2 miles, and predominant past-year wind direction. Indices were categorized (low/middle/high) for swine and poultry separately. We estimated prevalence differences (PD) for current wheeze and asthma by exposure category, using linear binomial regression with inverse-probability weights to control confounding by gender, age, school, time outside, lunch assistance, passive smoke exposure, and livestock exposure (ie, chores). Of 326 participants with complete data, 93% lived within 2 miles of at least one AFO. Prevalence of current wheeze and current asthma were 24.0% and 10.6%, respectively. In crude data, neither swine nor poultry exposure index was associated with current wheeze or current asthma. After controlling for confounding, middle and high swine exposure index categories were associated with higher prevalence for both outcomes compared to the lowest category (current wheeze PD per 100 adolescents: 11.3, 95% CI: 2.6, 20.0; current asthma PD: 5.9, 95% CI: -0.1, 11.9). Using a novel exposure metric and rich covariate data, we observed higher prevalence of current wheeze and asthma with higher swine AFO exposure. Future research should examine potential heterogeneity by sociodemographic or geographic factors.

### P03. Prenatal and Early Life Exposures and Effects 3

#### **P03.2470. Metallome-Wide Association Study of Maternal-Fetus Interface Metabolism Dysfunction in Gestational Diabetes Mellitus**

Heqing Shen

*Yan Wu<sup>1</sup>, Heqing Shen<sup>2</sup>*

*1. University of Chinese Academy of Sciences, Beijing, China.*

*2. Institute of Urban Environment, Chinese Academy of Sciences, Xiamen, China.*

**Abstract:** A broad set of elements has been linked to gestational diabetes mellitus (GDM); the previous study also acknowledged some metabolic biomarkers in meconium can provide the biology of GDM. This work was to assess a set of elements' associations with GDM and infer the causality by using the maternal-fetus interface surrogating sample of meconium. We conducted a case-control study nested on the cross-sectional retrospection of 1359 recruitments from the Xiamen Maternity and Child Care Hospital. The ICP-MS and ICP-OES was used to characterize the meconium metallome of 23 elements. The associations for some GDM-related elements, GDM-oriented metabolic biomarkers and GDM incidence were assessed by using redundancy analysis and Correlation-Adjusted corRelation. Mediation analysis was in further used to test the metabolic biomarker mediation between the elements and GDM incidence. The significant associations of eight elements with GDM incidence were observed, the risk elements are Al, As, Ba, Cd, Hg, and Sn and the preventive elements are Ca and V. Among them, As, Cd, Ba, and Ca can also explain the variation of GDM-oriented metabolites. 69% of the total variance of GDM incidence can be explained by all investigated factors and the elements had an independent predictive power of 16%. The investigated elements can also explain 39.5%, 26.58%, and 23.78% of the total variance of argininosuccinic acid, oxotrihydroxyleukotriene B4 and taurodeoxycholic acid, respectively, which are the top three metabolic determinants and can explain about 45% of the total GDM incidence. From more to less, the associations of Cd, Ba, Ca and As with GDM incidence have been mediated by the metabolic biomarkers. Ba, As and Cd aggravate GDM occurrence while Ca play the preventive role; the metabolic biomarker involved lipid metabolism and ALANO pathways may imply the elements' biological action on GDM. Notably the toxic effect of Ba and the beneficial effect of Ca on GDM have not been attended before.

**P03.2480. Associations between Maternal Exposure to Bisphenol A or Triclosan and Gestational Hypertension and Preeclampsia: The MIIREC Study**

Louopou Camara

*Louopou R. Camara<sup>1</sup>, Tye Arbuckle<sup>2</sup>, Helen Trottier<sup>3</sup>, William Fraser<sup>4</sup>*

- 1. Medecine sociale et preventive, Universite de Montreal, Montreal, QC, Canada.*

- 4. CHU Sherbrooke Research Center, Université de Sherbrooke, Sherbrooke, QC, Canada.*

**Abstract:** Background: Little is known about the association between bisphenol A (BPA) or triclosan (TCS) exposure and hypertension in pregnancy. Objective: To investigate potential associations between maternal urinary concentrations of BPA or TCS and gestational hypertension and preeclampsia. Methods: Among 1909 pregnant women participating in the (Maternal-Infant Research on Environmental Chemicals (MIREC) Study, urinary concentrations of BPA and TCS were measured in the first trimester by liquid chromatography-tandem mass spectrometry using isotope dilution. Blood pressure was measured during each trimester. Multinomial regression was performed to estimate the adjusted odds ratio (aOR) and 95% confidence intervals (CI) for the associations between these phenols and gestational hypertension and preeclampsia. Results: BPA urinary concentrations were similar according to hypertension status: The median (interquartile range) concentrations were 0.97 µg/L (0.40, 2.00), 1.10 µg/L (0.40, 1.90), and 0.80 µg/L (0.35, 1.70) for women with gestational hypertension, those with preeclampsia and normotensive women, respectively (p = 0.075). For TCS, the values were 10.04 µg/L (2.56, 76.26) for the group with gestational hypertension, 6.48 µg/L (1.48, 67.94) for those with preeclampsia and 8.56 µg/L (2.16, 67.35) for normotensive women (p = 0.559). Compared with the lowest tertile, BPA and TCS were not associated with gestational hypertension (aOR for BPA > 1.30 µg/L = 1.00; 95% CI: 0.54-1.81 and aOR for TCS > 32.6 µg/L = 1.41; 95% CI: 0.83-2.37) or preeclampsia (aOR for highest tertiles were 1.26; 95% CI: 0.53-2.97 and 0.68; 95% CI: 0.31-1.48, respectively). Conclusion: BPA and TCS urinary concentrations measured during the first trimester of pregnancy were not associated with gestational hypertension or preeclampsia. Additional studies are required to confirm our results.

### **P03.2490. Prenatal Blood Manganese Levels and Postpartum Depression among Women in Mexico City**

Nia McRae

**Abstract:** Introduction: Previous studies have shown a positive association between manganese and depression symptoms. The effect of elevated manganese levels on depression may apply to postpartum depression as well due to postpartum depression being a subtype of depression. We examined the association between prenatal blood manganese levels and postpartum depression among women in Mexico City. Methods: Study subjects were 561 women from the PROGRESS birth cohort in Mexico City. Blood manganese levels were measured at 2nd and 3rd trimester, as well as delivery. The Edinburg Postnatal Depression Scale was used to assess postpartum depression. Adjustments were made for maternal age, prenatal stress, prenatal depression, education, socioeconomic status, and contemporaneous blood lead levels. Poisson regression was used to analyze depression scores. Results: Among our study participants, 17.11% reported having postpartum depression symptoms. In the crude analysis, blood manganese levels during the 3rd trimester, prenatal stress, and prenatal depression had a positive association, and women with more than a high school education had an inverse association with postpartum depression symptoms. In the adjusted model, blood manganese levels averaged at 2nd and 3rd trimester ( $\beta$ : 0.15, 95% CI: 0.02-0.28) and blood manganese levels during 3rd trimester ( $\beta$ : 0.13, 95% CI: 0.04-0.21) in which the adjusted lead measure was lead in the tibia bone at 1 month postpartum and blood lead at 3rd trimester, respectively, had a positive association with postpartum depressive symptoms. Higher blood manganese levels averaged at the 2nd and 3rd trimester ( $\beta$ : 0.14, 95% CI: 0.02-0.26) had a positive association with postpartum depression symptoms in which the adjusted lead measure was averaged at 2nd and 3rd trimester. Conclusion: The results of our study suggest that elevated prenatal blood manganese levels may increase the prevalence of postpartum depression symptoms.

### **P03.2500. Prenatal Cadmium Exposure Associates with the Expression of Placental Imprinted Genes Overall, and in Sex-Specific Patterns**

Todd Everson

Abstract: Prenatal Cd exposure has been recognized to restrict growth, and male and female fetuses may have differential susceptibility to the developmental toxicity of Cd. Imprinted genes, which exhibit mono-allelic expression based on parent-of-origin, are highly expressed in placental tissues, contribute to fetal growth development and some of which are also expressed in sex-specific patterns. We aimed to identify whether prenatal Cd is associated with the expression of imprinted placental genes, overall or in fetal sex-specific patterns, across two independent epidemiologic studies. We regressed the placental expression levels of 72 putative imprinted genes on placental log-Cd concentrations while adjusting for maternal age, sex, smoking history, and educational attainment. These models were performed within study- and sex-specific strata in the New Hampshire Birth Cohort Study (NHBCS, n=326) and the Rhode Island Child Health Study (RICHS, n=214). We then used fixed-effects models to estimate the pooled associations across strata and examined heterogeneity in the associations by fetal sex. We identified 6 imprinted genes that were differentially expressed with log-Cd at the Bonferroni-adjusted alpha ( $p$ -values < 0.00069). Of particular note, higher Cd concentrations were associated with higher expression of GAA ( $p$ -value = 0.0000033) and DLX5 ( $p$ -value = 0.000012), and lower expression of H19 ( $p$ -value = 0.00018) across study and sex-specific strata. We also found that the placentae of female fetuses appeared more susceptible to Cd-associated increased imprinted expression. The differential regulation of these imprinted genes in association with prenatal Cd exposure may be involved in the overall developmental toxicity and contribute to the apparent unique Cd-responses of male and female placentae.

**P03.2510. Contribution to the Understanding of Biologic Concentrations of Metals in the Newborns in an Urban Area from Rio de Janeiro, Brazil**

**Abstract:** Background/Aim: Environmental exposure to heavy metals in urban areas has been associated with adverse birth outcomes such as spontaneous abortion, stillbirth, preterm birth, low birth weight, small for gestational age birth, and lower head circumference. To evaluate prenatal exposure and to test viability for a birth cohort study, a pilot study was conducted in newborns at the School Maternity of the Federal University of Rio de Janeiro (ME-UFRJ). The aim of this study is to evaluate exposure to metals of interest to Public Health (Lead, Mercury, Arsenic and Cadmium) in newborns in an urban area. Methods: During the months of October and November of 2017, all pregnant women attended at ME-UFRJ, over 16 years of age, were invited to participate in the project. Were collected 1) socioeconomic, cultural, leisure and living conditions of the parents 2) Maternal biological samples (blood, urine and hair) 3) Cord blood, anthropometric data, APGAR and urine of the newborn. Results: Of the 209 pregnant women attended, 142 accepted to participate (67.9%), 4 of whom were twin pregnancies (2.8%). From October / 2017 to February / 2018, there were 131 births (92.3%), and cord blood was collected from 122 births (85.9%). Expected results: The data analysis and the laboratory results will be available in May 2018 and will be presented at the conference Conclusion: This study may contribute to the increase of knowledge regarding exposure to metals, and its predisposing factors or conditions, of newborn in an urban area in Brazil.

### **P03.2520. Urinary Measures of Glyphosate and Oxidative Stress in Pregnant Women**

**Abstract:** Glyphosate (GLY) is the most heavily used herbicide in the United States. Its residues found in all environmental mediums, major crops, and food items that are daily consumed by Americans. In-vivo and in-vitro studies suggest GLY disrupts important endocrine mediated pathways, and causes oxidative DNA damage in animal and human breast epithelial and placental cells. Our published birth cohort study provides first urinary measures of GLY in a regional cohort of 71 pregnant women, and confirms 93% detection rate, with significant risk of shorter gestation length ( $r=-0.28$ ,  $p=0.01$ ). Our findings suggest that GLY exposure may be prevalent in millions of pregnant women, and places pregnancies and newborns at risk. Therefore, a follow up study was designed to examine whether GLY increases the risk of oxidative DNA damage in human pregnancies, a known pathophysiology indicator of many reproductive complications, including shortening of pregnancy. Our central hypothesis is that higher urinary GLY levels will be correlated with oxidative biomarkers. We measured 8-hydroxy-deoxyguanosine (8-OHdG) and 8-iso-prostaglandin F2a (Isoprostane) as the urinary biomarkers of oxidative stress in the stored urine specimens of pregnant women. We measured 8-OHdG using immunoassay, and Isoprostane using liquid chromatography-mass spectrophotometry. Currently, we are analyzing the generated data to develop correlations between the measured levels of urinary GLY and oxidative biomarkers. This study offers innovation as it is the first time GLY exposure levels will be correlated with oxidative stress biomarkers in human pregnancies, which are currently unknown and will serve as a basis for future investigations.

**P03.2530. Increased Risk of Phthalates Exposure for Recurrent Spontaneous Abortion in Reproductive-Aged Women: Taiwan Female Infertility Study (TIFF)**

Po-Chin Huang

*Kai-Wei Liao<sup>1</sup>, Pao-Lin Kuo<sup>2</sup>, Han-Bin Huang<sup>3</sup>, Jung-Wei Chang<sup>4</sup>, Hung-Che Chiang<sup>5</sup>, Po-Chin Huang<sup>1</sup>*

- 5. College of Medicine, China Medical University, Taichung, Taiwan.*

**Abstract:** Background/Aim Recurrent spontaneous abortion (RSA) is the termination of pregnancies, usually before 20 weeks of gestation. Some studies indicated that phthalates may involve in the pathogenesis of RSA, and that Taiwan's reproductive-aged women were still exposed to high levels of DEHP and DBP after 2011 DEHP exposure episode. We aimed to assess the risk of phthalates in Taiwanese women with RSA using a case-control study design. Methods We recruited 103 RSA patients and 76 controls from the department of obstetrics and gynecology in a hospital in southern Taiwan from 2013 to 2017. Urine samples were analyzed for 11 phthalate metabolites through LC/MS-MS; subsequently, principal component analysis (PCA) and agglomerative hierarchical clustering analysis were performed to determine the main sources of phthalate exposure. Multivariate logistic regression was used to determine the RSA risk. Results Median levels (ng/mL) of mono-n-butyl phthalate (MnBP), mono-iso-butyl phthalate (MiBP), mono-(2-ethyl-5-hydroxyhexyl) phthalate (MEHHP), mono-(2-ethyl-5-carboxypentyl) phthalate (MECPP),  $\Sigma$ DBPm, and  $\Sigma$ DEHPm were 3.1/27.2, 5.3/9.8, 8.1/11.4, 9.5/12.9 ng/mL, 0.10/0.18 nmol/mL, and 0.12/0.15 nmol/mL respectively, in control/RSA. PCA revealed three primary components of phthalate exposure: DEP, DBP, and DEHP. Plastic food container use and medication use were identified as the main phthalate exposure sources. After adjustment for creatinine, age, age at menarche, educational level, plastic food container use, and food preservation bag use, we observed significantly high odds ratios for RSA: 3.15 ( $p=0.03$ ), 3.31 ( $p=0.04$ ), and 2.57 ( $p=0.07$ ) in the third tertile for MiBP,  $\Sigma$ DEHPm, and  $\Sigma$ DBPm, respectively. Conclusions Our findings support the hypothesis that exposure to phthalates increases RSA risk in Taiwanese women. The development of the strategy to avoid using phthalate coatings for oral medications and plastic products among reproductive-aged women should be emphasized.

**P03.2540. Pioglitazone Increases the Number of Ultrasonic Vocalization Impaired by Prenatal LPS in Rats, an Effect Not Related with Insulin and Leptin**

Abstract: Previous investigations by our group have demonstrated that prenatal exposure to lipopolysaccharide (LPS), which mimics infections by gram-negative bacteria, induces autistic-like behaviors. We used our rat model to test a possible treatment for autism. We selected pioglitazone because although it was designed as an anti-diabetic drug (insulin effect), it also exerts anti-inflammatory effects. Juvenile offspring were daily treated with pioglitazone and 50 kHz ultrasonic vocalization was studied because of its relation with communication and autism. Biomarkers linked to autism and/or pioglitazone were also studied to try to understand the mechanisms involved: insulin, and leptin. Prenatal LPS exposure reduced both the number and the total time of vocalizations, compared with the data from the control group. Post-treatment with pioglitazone increased the number of ultrasonic vocalization in the rats prenatally exposed to LPS, i.e., both doses of pioglitazone (0.25 or 1.0 mg/kg/day) increased the number of vocalizations, compared with the LPS group. However, only the pioglitazone treatment of 1.0 mg/kg/day associated with LPS affected insulin and leptin plasma levels, increasing it compared with the levels exhibited by the other groups. In conclusions, prenatal LPS exposure induced communicational abnormalities in juvenile rat offspring. Daily postnatal pioglitazone treatment blocked the ultrasonic vocalization deficits. The communicational abnormalities induced by prenatal LPS as well as the beneficial effects of pioglitazone seem not to be related with insulin and leptin. Capes and Unip.

### **P03.2550. Contrasting Associations between Exposure to Environmental Marine Pollutants and Reports of Immune System Disorders in Greenlandic Children**

Youssef Oulhote

*Youssef Oulhote<sup>1</sup>, Henning Pedersen<sup>2</sup>, Amalie Timmermann<sup>3</sup>, Pal Weihe<sup>4</sup>, Flemming Nielsen<sup>3</sup>, Philippe Grandjean<sup>3</sup>*

- 1. Environmental Health, Harvard T. H. Chan School of Public Health, Boston, MA, United States.*
- 2. Primary Health Care Clinic, Nuuk, Greenland.*
- 3. Department of Environmental Medicine, University of Southern Denmark, Odense, Denmark.*
- 4. Department of Occupational Medicine and Public Health, Faroese Hospital System, Tórshavn, Faroe Islands.*

**Abstract:** Background: Early-life exposures to environmental contaminants may modulate the development of immune system. Objective: To examine the associations between exposure to marine pollutants and prevalence of atopic diseases, antibodies and IgE concentrations. Methods: We examined 367 Greenlandic children aged 7 to 12 years from the IVAAQ and INUENDO pregnancy cohorts. Concurrent concentrations of Polychlorinated biphenyls (PCBs), Mercury (Hg), Hexachlorobenzene (HCB),  $\beta$ -hexachlorocyclohexane ( $\beta$ -HCH), and perfluoroalkyl substances (PFASs) were measured in children's blood. Diagnoses of asthma, allergy, eczema, rash, and hayfever were ascertained based on the standardized International Study of Asthma and Allergies in Childhood. We also measured Diphtheria and Tetanus antibodies and IgE concentrations in children's blood. We used generalized mixed effects models to estimate the associations between chemical concentrations and allergic diseases and antibodies concentrations. Results: Prevalence of asthma, allergy, eczema, rash, and hay fever was 14%, 13%, 14%, 17%, and 4%, respectively. We found positive associations between higher concentrations of HCB (Odds Ratios [OR] for a two-fold increase = 1.43; 95% Confidence Interval [CI]: 1.03, 1.98), Perfluorononanoic Acid (PFNA) (OR = 1.62; 95% CI: 1.01, 2.60), and Perfluorodecanoic Acid (PFDA) (OR = 1.33; 95% CI: 0.99, 1.81) and asthma prevalence. In contrast, we found negative associations between HCB, PFASs, and Hg, and prevalence of eczema. For instance, a two-fold increase in PFOS and PFOA concentrations was associated with 0.40 (95% CI: 0.24, 0.65) and 0.31 (95% CI: 0.14, 0.67) lower odds of eczema. Similar negative associations were observed for the prevalence of rash. No pattern of associations was found with IgE and antibodies concentrations. Conclusions: Despite the contrasting observed associations, these findings provide further evidence on the potential immunomodulatory effects of marine pollutants.

### **P03.2570. Childhood, Adolescence, and Agrochemicals: A Minefield to Inhabit**

Paulo Paz de Lima

*Paulo J. Paz de Lima<sup>1</sup>*

*1. ABRAPPS, São Paulo, São Paulo, Brazil.*

Abstract: Paulo Junior Paz de Lima - E-mail: [pjuniorpl@usp.br](mailto:pjuniorpl@usp.br) Telma de Cassia dos Santos Nery - E-mail: [telma.nery@hc.fm.usp.br](mailto:telma.nery@hc.fm.usp.br) For a decade, since 2008, Brazil has been among the top buyers of agrochemicals in the world. Its consequences include high rates of suicide, congenital malformations, high prevalence of mental illness, and high incidence of intoxication by agrochemicals in people aged from <1 to 19. Objective: investigating cases of intoxication from agrochemicals in Brazilians aged from <1 to 19. Methodology: Cross-sectional descriptive study, from the cases of notifications of intoxication by agrochemicals registered by SINAN/MS and SINITOX/Fiocruz in people aged from <1 to 19 in the period between 2005 and 2015. Results: Between 2007 and 2015, SINAN/MS was notified of 21,840 cases of intoxication by agrochemicals used in agriculture, at home, and in public health and by rodenticides. Of these, 6,075 cases were caused by agrochemicals of agricultural use; 9,607 victims were aged 15 to 19 and 1,509 were under 1 year of age. SINITOX registered 44,687 cases of intoxication by agrochemicals in people aged from <1 to 19. Discussion: Victims of intoxication by agrochemicals are not necessarily economically active. Exposure to and intoxication by agrochemicals are part of the reality of children since an early age; many are intoxicated while still in the womb of their mothers, who are rural workers. Conclusion: Intoxication by agrochemicals in children and teenagers can have severe lasting effects on physical or mental health, leading to learning difficulties if it happens during a stage of development of the body, the mind, and the personality. It is a public health issue that must be addressed carefully by governments, health professionals, educators, and researchers in order to develop specific studies with this population. Keywords: childhood, adolescence, agrochemicals, intoxication, health.

**Abstract:** Background: Few studies have investigated the associations between early household environmental exposures and adverse birth outcomes. Here we analyzed associations of household renovation in the year before pregnancy and during pregnancy with preterm birth (PTB, gestational age <37 weeks) and low birth weight (LBW, birth weight <2500 g). Methods: A retrospective cohort study was conducted for children from eight large cities of China (Beijing, Shanghai, Nanjing, Changsha, Wuhan, Chongqing, Urumqi, and Taiyuan) during 2010-2012. Parents responded to questions about household renovation and their child's gestational age and birth weight. Multiple regression and two-level (city-child) mixed-effect logistic regression analyses were performed to investigate the target associations. Results: A total of 35,807 subjects were analyzed. Herein 16.9% and 4.5% subjects had household renovation in the year before pregnancy and during pregnancy, respectively. A total of 4.1% and 2.6% children were PTB and LBW, respectively. In the multiple logistic regression analyses, household renovation in the year before pregnancy was significantly associated with LBW (adjusted odds ratio with 95% confidence intervals: 1.23, 1.01-1.50; p-value=0.036). Household renovation during pregnancy was significantly associated with PTB (1.28, 1.01-1.69; 0.048). Similar associations were found in the two-level logistic regression analyses. Conclusions: Household renovation before pregnancy could be a risk factor for LBW, while household renovation during pregnancy could be a risk factor for PTB. Avoidance of early household renovation would be an effective intervention to reduce adverse birth outcomes.

**P03.2590. Prenatal Exposure to Perfluoroalkyl Substances (PFASs), Polybrominated Diphenyl Ethers (PBDEs) and Polychlorinated Biphenyl 153 (PCB) and Anthropometric Measures in Children**

*5. Population Studies Division, Healthy Environments and Consumer Safety Branch, Health Canada, Ottawa, QC, Canada.*

**Abstract:** Background: The prevalence of overweight and obese children is rising but factors responsible for this problem are not clear, although nutrition and physical activity most likely play a role. In addition, some environmental chemicals are suspected to have 'obesogenic' effects through disruption of endocrine function, but the data is sparse. Objective: We aimed to examine the prospective association between prenatal exposure to several persistent environmental chemicals (i.e., PFASs, PBDEs, PCB) and anthropometric measures during childhood. Methods: We used data from the Maternal-Infant Research on Environmental Chemicals (MIREC) study, a pregnancy cohort recruited in 2008-2011 in Canada. Anthropometry was assessed at a median age of 3.3 y (standard deviation, 0.9 y), i.e. BMI and skin-fold thickness of the arm and back (n=757). PBDEs, PFASs and PCB were measured in first trimester maternal plasma. We used multiple regression analysis to assess the confounders-adjusted relation between maternal contaminant levels and anthropometric measures standardized for age and sex. Results: In the study, 31.9% of children were classified as overweight or obese based on WHO child growth standards. Maternal BPC 153 concentration was associated with higher child BMI (for a doubling in concentration  $\beta = 0.04$ , 95% CIs: 0.01, 0.06), greater skin-fold thickness of the arm ( $\beta = 0.17$ , 95% CIs: 0.12, 0.21) and back ( $\beta = 0.06$ , 95% CIs: 0.04, 0.09). PBDE 47 and 153 were associated with higher arm skin-fold thickness ( $\beta = 0.16$ , 95% CIs: 0.08, 0.24 and  $\beta = 0.17$ , 95% CIs: 0.12, 0.21, respectively). On the other hand, higher maternal levels of PFOS was associated with decreased BMI ( $\beta = -0.17$ , 95% CIs: -0.30, -0.04); the odds for being overweight or obese were 0.61 (95% CI: 0.15, 0.83) for a doubling in PFOS concentration. Conclusion: Prenatal exposure to some PBDEs and PCBs may be associated with an increasing adiposity in childhood, whereas we found suggestion of inverse relation with PFOA.

**P03.2600. Surveillance of Arsenic and Lead Exposure in Mother-Child Pair from Arica, Chile 2013-2016**

Macarena Valdes

*Macarena Valdes<sup>1</sup>, Karla Yohannessen<sup>2</sup>, Maria P. Munoz<sup>1</sup>, Veronica Iglesias<sup>1</sup>*

*1. Epidemiology, University of Chile. Public Health School., Santiago, Chile.*

*2. Environmental Health, University of Chile. School of Epidemiology, Santiago, Chile.*

**Abstract:** Introduction: During the 80 and 90's, the polymetallic rubbish derived from Sweden and the transportation of minerals between Chile and Bolivia, exposed many urban zones in Arica, Chile. It was needed to implement a surveillance of polymetallic exposure in the population. The aim of this study was to describe the concentrations of arsenic in pregnant women and lead in the umbilical cord blood of newborns included in the surveillance of polymetallic exposure of the births occurred between 2013 and 2016 in Arica, Chile. Method: Cross-sectional design. 1676 mothers and 1706 children attended in public health facilities and whose birth occurred between 2013 and 2016 was characterized using a standard questionnaire implemented in the surveillance of arsenic and lead exposure. A sample of urine was taken from mothers in order to measure inorganic arsenic (As-I), and an umbilical cord blood sample was taken during the birth to determine lead concentration. Sociodemographic data were obtained from the surveillance survey. The univariate and bivariate analyses were used to describe both pollutants in the mother-child pair. Multiple logistic regression was done to explore the association between an arsenic concentration above 35mg/L and risk factors. Results: The median of urinary As-I was 15 mg/L (Min-Max: 2.5-127); the proportion of urinary As-I above 35 mg/L was 7.4%, and the risk factors related to this were shellfish consumption and street paving. The median of lead was 0.5 mg/dL (Min-Max: 0.5-6). The lead concentration above 5 mg/dL was less than 1%, and none of the risk factors included in this analysis was significantly associated. Conclusion: The arsenic concentration showed a wide variability; it might suggest different sources of exposure such as shellfish consumption and street paving. Given the low lead concentrations and scarce variability of the data, surveillance is suggested only in subsamples of the population.

### **P03.2610. Gestational Urinary Bpa Concentrations and Child Adiposity at Age 3 Years: The MIREC Study**

Joseph Braun

**Abstract:** Background: Bisphenol A (BPA) is a high production volume chemical, and because of its use in numerous consumer products, exposure is ubiquitous. Prenatal BPA exposure has been associated with excess adiposity in rodent studies, but not consistently in human studies. Objectives: We investigated the relation between prenatal BPA exposure and early childhood adiposity in a prospective cohort study of 686 mother-child pairs. Methods: We used data from the Maternal Infant Research on Environmental Chemicals (MIREC) Study, a prospective pan-Canadian pregnancy and birth cohort study. We measured BPA in urine samples collected at an average of 13 weeks gestation. In six of the cities, we measured children's weight, height, waist/hip circumference, and subscapular/triceps skinfold at an average of age 3.4 years. Using linear regression, we estimated covariate-adjusted associations between log<sub>2</sub>-transformed urinary BPA concentrations and adiposity measures. Results: Median urinary BPA concentrations were 0.8 ng/mL (IQR: 0.5-1.4). Among all children, there was no association between BPA and child adiposity. However, the association of BPA with waist circumference and subscapular skinfold thickness was modified by child sex (sex x BPA interaction p-values<0.2). Among girls, each 2-fold increase in urinary BPA concentrations was associated with a 0.3 cm (95% CI: 0, 0.5) and 0.2 mm (95% CI: 0, 0.3) increase in waist circumference and subscapular skinfold thickness, respectively. Among boys, BPA was weakly inversely associated with subscapular skinfold thickness (b: -0.1; 95% CI: -0.3, 0.1), but was not associated with waist circumference (b: 0.03; 95% CI: -0.19, 0.25). Conclusions: In this cohort, prenatal urinary BPA concentrations were associated with subtle increases in measures of central adiposity during early childhood among girls, but not boys. Future studies should confirm these associations and determine if they persist into later childhood.

### **P03.2620. Exposure to Polybrominated Diphenyl Ethers (PBDEs) during Childhood and Adiposity Measures at Age 8 Years**

Ann Vuong

*Ann Vuong<sup>1</sup>, Joseph M. Braun<sup>4</sup>, Kimberly Yolton<sup>5</sup>, Changchun Xie<sup>1</sup>, Andreas Sjodin<sup>2</sup>, Glenys Webster<sup>3</sup>, Bruce Lanphear<sup>3</sup>, Aimin Chen<sup>1</sup>*

**Abstract:** Background: Polybrominated diphenyl ethers (PBDEs) have been reported to be obesogens in laboratory studies. Only a few epidemiologic studies have investigated childhood PBDEs and adiposity; most reported an inverse association. Methods: We examined longitudinal data of 187 children in the Health Outcomes and Measures of the Environment Study, a pregnancy and birth cohort enrolled in Cincinnati, OH (2003-2006). We measured serum PBDEs (BDEs-28, -47, -99, -100, and -153) at ages 1, 2, 3, 5 and 8 years; multiple imputation was used to estimate missing PBDE concentrations, mostly at younger ages. At age 8 years, we assessed weight and body mass index (BMI) z-scores, waist circumference, and bioelectrical impedance based body fat percentage. To account for repeated PBDEs and to test for potential windows of susceptibility, we used multiple informant models to estimate covariate-adjusted age-specific associations between childhood PBDEs and adiposity measures. Results: We observe significant inverse associations between BDE-153 concentrations at ages 5 and 8 years and weight and BMI z-scores. A 10-fold increase in BDE-153 at ages 3, 5, and 8 was significantly associated with lower body fat (~2-4%). Ten-fold increases in BDE-153 at ages 5 and 8 years were significantly associated with decrements in waist circumference ( $\beta$ =-3.0 cm, 95% CI -5.4, -0.6;  $\beta$ =-5.4 cm, 95% CI -7.8, -2.9, respectively). No statistically significant associations were found between BDE-28, -47, -99, or -100 and measures of adiposity. Effect measure modification by child sex was noted, with significant decrements in body fat percentage observed in males ( $\beta$ =-2.8, 95% CI -5.1, -0.4) with higher concurrent BDE-153, but close to a null association in females ( $\beta$ =0.2, 95% CI -5.1, 5.6). Conclusions: Childhood BDE-153 concentrations were inversely associated with weight and BMI z-scores, body fat percentage, and waist circumference. We cannot rule out reverse causality due to PBDEs' lipophilic nature.

### **P03.2630. Early-Life Triclosan Exposure and Behavior Problems in 8-Year-Old Children**

Medina Jackson-Browne

*Medina Jackson-Browne<sup>1</sup>, George Papandonatos<sup>2</sup>, Aimin Chen<sup>3</sup>, Antonia Calafat<sup>4</sup>, Kimberly Yolton<sup>5</sup>, Bruce P. Lanphear<sup>6</sup>, Joseph M. Braun<sup>1</sup>*

**Abstract:** Background: Triclosan may decrease circulating thyroxine levels or interfere with thyroid hormone signaling to adversely affect neurodevelopment. However, we are unaware of studies examining associations between triclosan exposure and childhood behavior problems. Methods: We used data from mother-child pairs enrolled in a Cincinnati, OH pregnancy and birth cohort study between 2003-2006 (The HOME Study). In 202 mother-child pairs, we quantified urinary triclosan concentrations in up to 3 maternal samples collected between 2nd trimester of the pregnancy and delivery, and in up to 6 child samples between ages 1 and 8 years. Caregivers rated their children's behavior at age 8 years using the Behavioral Assessment System for Children-2. We used a two-stage model to estimate changes in behavior problem scores with a 10-fold increase in mean gestational or childhood triclosan concentrations, accounting for triclosan exposure measurement error. Results: Gestational triclosan was positively associated with externalizing problem scores and some related clinical subscales; these associations were stronger in boys than girls (triclosan x sex interaction p-values < 0.2). Specifically, each 10-fold increase in gestational triclosan was associated with higher externalizing ( $\beta$ : 5.0; 95% CI: 1.1-8.9), attention ( $\beta$ : 6.4; 95% CI: 2.2-11), and hyperactivity ( $\beta$ : 6.4; 95% CI: 2.2-11) scores in boys. We observed a similar pattern of associations of childhood triclosan with externalizing and related clinical subscales, but these associations were substantially attenuated after we adjusted for gestational triclosan. In contrast, associations between gestational triclosan and behavior problems were slightly attenuated. In general, triclosan concentrations were not associated with internalizing problems. Conclusion: In this cohort, gestational urinary triclosan concentrations were associated with more externalizing, inattention, and hyperactivity behaviors at age 8 years in boys, but not girls.

**P03.2640. An mHealth Platform for Predicting Risk of Pediatric Asthma Exacerbation Using Personal Sensor Monitoring Systems: The Los Angeles Prisms Center**

**Abstract:** Pediatric asthma is a complex and heterogeneous chronic disease that affects millions worldwide and results in significant morbidity and mortality. Studies have shown environmental exposures such as air pollution to be associated with risk of asthma attacks, but little is known about the time lag between exposure and response, the role of multiple exposures in context, and variation in personal risk at short temporal and fine spatial scales. As part of the Los Angeles PRISMS Center, the LA PRISMS Breathe (Biomedical Real-Time Health Evaluation) Kit is being developed as a non-invasive, secure end-to-end informatics platform that utilizes the latest in mHealth technologies to advance environmental health studies of pediatric asthma. The platform is based on a smartwatch/smartphone that securely and wirelessly communicates with a suite of personal environmental, physiological and health sensors in real time and collects self-report symptoms data and contextual information using Ecological Momentary Assessment methods. External environmental data such as meteorology, traffic and air quality is also collected based on time and location of the participant. Data is integrated and analyzed to build individualized exposure and asthma exacerbation prediction models and the information is fed back to asthmatics, caretakers and physicians to improve asthma management. This talk will present key components of the Breathe Kit and its deployment in environmental health research studies, including participant engagement, compliance and burden considerations. Data from preliminary pilot testing in a panel study of children with asthma recruited from the UCLA Pediatric Pulmonology clinic will be presented. The ultimate goal of the LA PRISMS Breathe Kit is to be able to predict a looming asthma attack in an individual so that early intervention methods can mitigate if not prevent the episode entirely.

### **P03.2650. Analysis of Perfluoroalkyl Substances in Deciduous Teeth**

Abstract: Researchers continue to explore novel sources of biospecimens suitable for quantifying environmental toxins at the population level. Deciduous teeth have been used for decades to quantify exposure to heavy metals in children. The mineralization of primary teeth begins around mid-gestation and concludes at age 1 year. After this period, dentine undergoes very limited remodeling and thus preserves concentrations of environmental toxins. Whether deciduous teeth can be used as biospecimens to measure early exposure to organic chemicals remains unclear. We explored the feasibility and utility of such an approach using the Upstate KIDS Study (2008-2010, upstate New York). We previously quantified 2 perfluoroalkyl substances (PFASs) [perfluorooctanoic acid (PFOA) and perfluorooctane sulfonate] in newborn dried blood spots (DBS) for participating children. We collected deciduous teeth from 64 children (38 singletons and 26 twins, 1 tooth per child). After pulverizing each tooth, samples were extracted by methyl-tert-butyl ether. The extracts were analyzed by liquid chromatography-tandem mass spectrometry to measure 13 PFASs. Limit of quantitation ranged from 0.2 ng/g for perfluorooctanesulfonamide to 1.85 ng/g for perfluorodecane sulfonate. PFOA was detectable in 10 (15% of 64) samples; perfluorononanoic acid and perfluoroheptanoic acid in 1 sample each. Other PFASs were not detected. The mean (SD) PFOA concentrations in 10 samples was 0.83 ng/g (0.39 ng/g) (median=0.65 ng/g; range=0.57-1.56 ng/g). Despite the low number detectable, the correlation of PFOA concentrations quantified in teeth and in DBS was  $r=0.76$ ,  $p=0.08$  ( $n=6$  with both measurements). Median PFOA concentrations, quantified in DBS, did not differ between the 38 children with no PFOA detected in tooth samples compared to 6 with detected PFOA [1.18 ng/ml, interquartile range (IQR)=1.02 vs. 0.97 ng/ml, IQR=0.62]. In conclusion, our results suggest that deciduous teeth underestimate children's exposure to PFASs.

**P03.2660. Bisphenol A in Different Compartments for Mother-Fetus Pairs in Taiwan and Health Effects of Newborns**

Mei-Lien Chen

*Mei-Lien Chen*<sup>1</sup>

*1. Institute of Environmental and Occupational Health Sciences, National Yang-Ming University, Taipei, Taiwan.*

Abstract: Bisphenol A (BPA) is found in many consumer products as it is used to produce polycarbonate plastics and epoxy resins. It is a well-known endocrine disruptor and has drawn great concern on the adverse effects on the growing fetus and neonates. The aims of this study were (1) to determine BPA levels in different compartment of mother-fetal pairs, (2) to investigate the correlation between birth outcomes and prenatal exposure to BPA, and (3) to evaluate the potential risk from exposure to BPA for the breast milk fed infants. We analyzed 65 mother-fetus pairs' maternal urines, placenta, cord blood, and 1st& 3rdmonth breast milk by UPLC/TOF-MS. A questionnaire was used to collect socio-demographic data and information about birth outcomes was obtained from medical records. The daily intake of BPA in breast milk was calculated using probabilistic risk assessment methods. The GM (GSD) of BPA levels in maternal urine, fetal cord blood, placenta, first and three month breast milk were 2.08 (3.18)  $\mu\text{g/g}$  creatinine, 3.73(2.40)ng/mL, 3.39(2.13)ng/g, 1.35(3.59) and 2.90(2.85)ng/g, respectively. There are no significant associations between pregnant women urine, fetal cord blood and placental BPA levels and birth outcomes in this study. Three percent of one-month-old babies and one percent of three-month-old babies exceeded 4  $\mu\text{g/kg-bw/day}$ , proposed as temporary TDI by the European Food Safety Authority. In conclusion, this study provides the exposure profile and distribution of BPA in different compartments among mother-fetus pairs in Taiwan. Only few infants were exposed to BPA levels exceeding the temporary TDI BPA.

## **P03.2670. The New York University Children's Environmental Health Study (NYU CHES): Design and Objectives**

Linda Kahn

- 2. Population Health, New York University School of Medicine, New York, NY, United States.*

**Abstract:** The New York University Children's Environmental Health Study (NYU CHES) is an NIH ECHO-funded birth cohort designed to assess the impact of prenatal exposure to environmental chemicals on pregnancy, child, and postnatal maternal health. Since March 2016, NYU CHES has enrolled women from 3 NYU-affiliated hospitals at <18 weeks gestation. Participants provide biosamples and questionnaire data in all 3 trimesters and at birth. Cord blood and placental samples are collected at delivery. Participants complete online surveys or phone interviews at child ages 4 and 8 months. At 12 months, mothers and children undergo physical assessments and body composition analyses, children provide urine and stool samples and are screened for developmental delays, and mothers provide urine samples and undergo tests of cardiovascular function. Future contacts will occur at 18 months (online/phone) and 2 years (in person). As of 3/28/18, 1347 women have enrolled of whom 696 (52%) have delivered, 7% have experienced pregnancy loss or termination, and 5% have been lost to follow-up. Participants are mean age 31.8 years (SD 5.8). Half (49%) self-identify as Hispanic, 33% as White, 6% as Black, and 8% as Asian. Two-thirds are employed (64%), have at least some college education (65%), and have annual household income  $\geq$ \$50,000 (65%). Among women who have delivered, 523 (75%) have consented to postnatal follow-up and 11% are in the process of being recruited. Among offspring, 8% were preterm (<37 weeks) and 7% were low birth weight (<2500 g). Prenatal recruitment continues at an average of 17 new participants per week. Prenatal urine samples are currently being assessed for non-persistent chemicals (bisphenols and metabolites of phthalates, organophosphates, and polycyclic aromatic hydrocarbons). Initial analyses will examine associations among maternal chemical exposure, cytokine levels, thyroid function, blood pressure, gestational weight gain, fetal growth, and birth outcomes.

### **P03.2680. Urinary Trace Metals Individually and in Mixtures in Association with Preterm Birth**

Abstract: Preterm birth (PTB), birth <37 weeks gestation, affects 1 in 10 births in the United States. Though some risk factors have been identified, most causes remain unknown. Exposure to high levels of metals has been linked to higher risk of PTB, but consequences of lower levels of exposure, less studied metals, and combinations of these factors are unclear. In collaboration with the Children's Health Exposure Analysis Resource, we examined the association between 17 urinary trace metals and PTB. The LIFECODES birth cohort enrolled pregnant women at <15 weeks gestation at Brigham and Women's Hospital in Boston. Women participated in 4 study visits. We selected cases of PTB (n=99) and unmatched controls (n=291) and analyzed urine samples from visit 3 (median: 26 weeks) using mass spectrometry. We used logistic regression models to calculate odds ratios (OR) for PTB, controlling for maternal age, race, education, pre-pregnancy body mass index (BMI), specific gravity, and gestational age at time of urine collection. We used elastic net (ENET) regularization methods to determine which metals were driving the association with PTB and whether there were any meaningful interactions between exposures. We observed increased odds of PTB (OR: 1.88, 95% CI: 1.24, 2.86) associated with an interquartile range difference of copper (Cu). We also observed an elevated OR for selenium (OR: 1.92, 95% CI 0.95, 3.87). In addition, we observed small differences in associations with individual metals by presentation of PTB. The ENET methods selected Cu as the primary driver in the association with PTB. ENET also selected interactions between Cu and several other metals, including cadmium, molybdenum, selenium, and zinc. Our results suggested that Cu concentration in mothers at the 3rd trimester was associated with increased risk of PTB, despite Cu being an essential nutrient.

### **P03.2700. Measures of Maternal Psycho-Social Stress and Biomarkers of Stress Response in the Maternal-Fetal Unit**

Rachel Morello-Frosch

*4. Department of Biochemistry and Biophysics, University of California, San Francisco, San Francisco, CA, United States.*

**Abstract:** In a cohort of 500 pregnant women recruited from two San Francisco hospitals serving economically and ethnically diverse populations, we used Targeted Minimum Loss-Based Estimation (TMLE) to evaluate the association between perceptual measures of maternal psycho-social stress and two biological measures of stress response: 1) telomere length (TL) in umbilical cord blood leukocytes collected at delivery, and 2) corticotropin-releasing hormone (CRH) in maternal plasma collected during the 2nd trimester. We evaluated ten dimensions of maternal stress, derived from questionnaires: job-related, neighborhood, community standing, experience of racism, perceived stress, acute stressful events, depression, pregnancy satisfaction, nativity, and material deprivation. All domains were identified as important predictors of TL/CRH in non-parametric variable important analyses. Therefore, CRH analyses included all stressors and were adjusted for pregnancy complications, mother's age, parity, and race/ethnicity. TL analyses were additionally adjusted for infant sex, and gestational age at birth. 30% of participants identified as Latina, 7% Black, 40% White, 16% Asian, and 7% identified as other/mixed. Less than 10% of women did not complete high-school and 60% had a bachelor's degree or higher. Biologic factors were more important at predicting TL than stress. Conversely, stress was more important at predicting CRH than biological factors. Counter-intuitively, experiencing racism (0.15, 95% CI: 0.12-0.17) and perceived stress (0.24, 95% CI: 0.21-0.27) were associated with greater TL (expressed as the relative ratio of telomere repeat copy number to single-copy gene copy number or T/S ratio). Pregnancy complications were associated with elevated CRH (0.13, 95% CI: -0.02-0.28), while pregnancy dissatisfaction was associated with lower CRH (-0.15, 95% CI: -0.30-0.01). Results suggest complex relationships between perceived stress and response biomarkers in the maternal-fetal unit.

### **P03.2710. The Effects of Maternal Cadmium Exposure and Attention Deficit Hyperactivity Disorder in Children 6 Years of Age**

Woo Sung Kim

**Abstract:** BACKGROUND: Prenatal environmental cadmium exposure in children may be associated with attention deficit hyperactivity disorder (ADHD) in children. OBJECTIVE: To examine the relationship between the heavy metal cadmium exposure during gestation and child ADHD at 6 years of age. METHODS: As part of an on-going cohort named "The Environment and Development of Children", 203 mother-child pairs from Seoul, Korea were enrolled between 2008 and 2011. Whole blood concentration of cadmium was analyzed. Multivariable linear regression models were used to investigate the relationship between exposure to cadmium with ADHD. RESULTS: Prenatal cadmium concentrations were associated with increased scores for ADHD at 6 years of age. Each 2-fold increase in prenatal cadmium level was significantly associated with an 23.8% [95% confidence interval (CI): 13.2%, 35.4% ] increase in Attention Deficit Hyperactivity Disorder in 6 year old children, as indicated by the linear regression model. CONCLUSION: Our results identified associations between prenatal cadmium levels with ADHD at 6 years of age. This research was supported by a grant (18162MFDS121) from Ministry of Food and Drug Safety in 2018 and Center for Environmental Health through the Ministry of Environment.

**P03.2720. Hormonal Changes at Early Age and Prenatal Exposure to Phthalates and Bisphenol A in a Cohort of Cuernavaca, Morelos, Mexico**

Hernández Leticia

*Hernández C. Leticia<sup>1</sup>, Jorge O. Acosta Montes<sup>1</sup>, Consuelo Escamilla Nuñez<sup>1</sup>, Albino B. Villarreal<sup>1</sup>, Isabel Alvarado Cruz<sup>1</sup>, Larissa Barbosa-Sánchez<sup>1</sup>, Isabelle Romieu<sup>2</sup>*

*2. IARC, Lyon, France.*

Abstract: Has been suggested that phthalate and BPA A exposure in utero may impact hormone concentrations and evolve the onset of early puberty. The objective of this study was to evaluate the association between prenatal exposures to phthalates and hormonal levels at 9 years old in a Cuernavaca, Morelos birth cohort (POSGRAD study). In a subsample of 314 children, total testosterone hormone levels and dehydroepiandrosterone sulfate (DHEA-S) were measurements from serum samples at 9 years of age from both sex. These levels were contrasted with the concentrations of 9 different metabolites of phthalates [Mono-2-ethylhexyl phthalate (MEHP), Mono-2-ethyl-5-carboxypentyl phthalate (MECPP), Mono-2-ethyl-5-hydroxyethyl phthalate (MEHHP), Mono-2-ethyl-5-oxohexyl phthalate (MEOHP), Mono-3-carboxypropyl phthalate (MCPP), Monobenzyl phthalate (MBzP), Monobutyl phthalate (MBP), Mono-iso-butyl phthalate (MiBP) and Mono ethyl phthalate (MEP)], and Bisphenol A in urine resulting from samples of mothers during the second trimester of pregnancy, through a multiple linear regression model adjusted for anthropometric variables of the child and sociodemographic characteristics. RESULTS. A significant relationship was observed with the LnMECPP and LnMEHHP with total testosterone levels, (increase of 13%, IC95%: 0.9%, 24%, and 11% increase, IC95% 0.16% to 23.6% en IU / L, by unit of increase in each metabolite, respectively. No metabolite showed a statistically significant association with DHEA-S levels, however, in girls who initiated menarche at 9 years old, significant association were observed with MiPB, MBzP and BPA with an increase of DHEA-S. DISCUSSION. Our results are consistent with previous studies in which it has been suggested that prenatal exposure can to induce can lead to early puberty. In our case, the exposure window was during the second trimester suggesting more prevention in this stage of life.

**P03.2730. Urinary 3-Phenoxybenzoic Acid Concentrations In Utero and in Childhood: Association with BMI Z-Score in 4-Year-Old Children**

**Abstract:** Background Pyrethroids, a class of ubiquitous insecticides, have been considered as endocrine-disrupting chemicals. The use of pesticides has increased over the past few decades, which raise concerns on possibility of health effects, particularly in children. However, only a few studies have been conducted to examine the relationship between 3-phenoxybenzoic acid (3-PBA) and children's health effects. Because exposure to 3-PBA may affect children's growth, we aimed to evaluate the association between prenatal and postnatal 3-PBA concentrations and body mass index in 4-year-old Korean children. Method We used the data from 578 children (309 boys and 269 girls; 45-55 months) at 4 years of age who were born from women who participated in the Environmental and Development in Children (EDC) cohort study from August 2008 to July 2011. Urinary 3-PBA concentration from mother at around 20 weeks of gestation and 4-year-old children was measured as prenatal and postnatal 3-PBA exposure, respectively. Result The geometric mean of BMI z-score of 4-year-old children was 1.308 and 95 percentile of BMI z-score was 1.389. Urinary 3-PBA was detected in 98.9-99.8% of prenatal and postnatal urine samples. The relationship between 3-PBA exposure at 4-year-old and BMI z-score of 4-year-old children was positively significant (p-value=0.0426). After sex stratification, the association remained significant among girls (p-value=0.0041), but not among boys. However, there is no association between prenatal 3-PBA exposure and BMI z-score at 4 years of age (p-value=0.6210). Conclusion Childhood adiposity measured as BMI Z-score was associated with urinary 3-PBA concentrations in children at 4 years of age. Keywords Pyrethroid, 3-phenoxybenzoic acid, BMI Z-score, children Funding's This research was supported by a grant (18162MFDS121) from Ministry of Food and Drug Safety in 2018 and Center for Environmental Health through the Ministry of Environment.

### **P03.2750. Phthalates Exposure Is Positively Associated with Increased Risk of Microalbumin in the General Taiwanese**

Po-Chin Huang

*Po-Chin Huang<sup>1</sup>, Kai-Wei Liao<sup>1</sup>, Chien-Yuan Huang<sup>3</sup>, Jung-Wei Chang<sup>2</sup>*

*1. National Institute of Environmental Health Sciences, National Health Research Institutes, Miaoli County, Taiwan.*

*2. Institute of Environmental and Occupational Health Sciences, National Yang-Ming University, Taipei, Taiwan.*

*3. Department of Occupational Medicine, Chi-Mei Medical Center, Tainan, Taiwan.*

**Abstract:** Background/Aim Phthalates (PAEs) are well-known endocrine disruptors and previous studies indicated that human exposed to phthalate-tainted products were positively associated with increased urinary microalbumin. We aim to assess the relationship between PAEs exposure and renal function index in the general Taiwanese. Methods We enrolled 311 subjects [ $\geq 40$ / $<40$  years old (yrs), N=183/128] who provided questionnaire, blood and urine samples from the Taiwan Environmental Survey for Toxicants (TESTs) 2013. Urinary PAEs metabolites were analysed by LC/MS-MS. We measured levels of serum blood urea nitrogen (BUN), and urinary creatinine, microalbumin, and protein. We calculated two renal function index, estimated glomerular filtration rate (eGFR) and microalbumin/creatinine ratio (ACR), in each subject. We used multiple and logistic regression or cumulative risk assessment (estimated HI values, HI<sub>hep</sub>) to evaluate the relationships between PAEs exposure and biomarkers or renal function index. Results Median (interquartile range) levels of urinary  $\Sigma$ DEHPm/ $\Sigma$ DBPm in subjects  $<40$  yrs were 0.29(0.17-0.44)/0.14(0.10-0.30)nmole/mL, which were higher than those  $\geq 40$  yrs ( $\Sigma$ DEHPm:0.19(0.12-0.32)/ $\Sigma$ DBPm:0.11(0.05-0.19) nmole/mL). Adjusted odds ratio of the highest quartile of estimated DEHP daily intake in subjects  $\geq 40$  yrs for abnormal microalbumin was 14.2 (95% confidence interval (CI)=1.52-133.3) fold higher than the lowest quartile group, whereas no risk was observed in subjects  $<40$  yrs. We found that cumulative HI<sub>hep</sub> were significantly increased with urinary microalbumin ( $\beta$ : 5.12, 95%CI:2.52- 7.72), ACR ( $\beta$ :1.12, 95%CI:0.005-2.23), and protein ( $\beta$ :3.05, 95%CI:0.94-5.12) in subjects  $\geq 40$  yrs after adjustment of age, sex, BMI, smoking, and drinking. Conclusions. Our findings suggested that high DEHP and cumulative PAEs exposure were significant positively associated with increased risk of urinary microalbumin. Large cohort and mechanistic studies are worthy to elucidate the associations.

**P03.2760. Variability of Urinary Phthalate Metabolite, Bisphenol, and Ultraviolet Filter Concentrations across Sensitive Windows of Human Reproduction**

Anna Pollack

*Anna Z. Pollack<sup>1</sup>, Jenna R. Krall<sup>1</sup>, Andrea Carmichael<sup>1</sup>, Kurunthachalam Kannan<sup>2</sup>, Germaine Louis<sup>3</sup>*

*1. Department of Global and Community Health, George Mason University, Fairfax, VA, United States.*

*2. Environmental Health Sciences, SUNY Albany/Wadsworth Center, Albany, NY, United States.*

*3. College of Health and Human Services, George Mason University, Fairfax, VA, United States.*

**Abstract:** Background: Pre-pregnancy and early pregnancy levels of phthalate, ultraviolet filter, and bisphenol exposure may be associated with adverse reproductive health endpoints. Characterizing variability across sensitive windows of human fecundity can assist in guiding epidemiologic study design of these exposures. In particular, no prior studies have characterized non-persistent endocrine disrupting chemicals across sensitive windows of human reproduction. Methods: We characterized the variability of 12 urinary phthalate metabolites, 6 bisphenol, and 5 ultraviolet filter concentrations prior to and during early pregnancy from 501 women with 1-4 samples per person collected from 2005-2009. Couples were recruited after discontinuing contraception prior to attempting a pregnancy and were followed daily until pregnant. The 343 (68%) women who became pregnant were followed daily through 7 weeks post-conception. We characterized chemical biomarker variability using intraclass correlation coefficients (ICCs) for women from the cohort overall, and by pregnancy status and race/ethnicity. Results: All ICCs (95% CIs) were <0.50 and varied by chemical class (in descending order): 0.46 (0.39, 0.52) for mEP, 0.36 (0.28, 0.43) for BP-1, 0.32 (0.24, 0.39) for BP-3, and 0.26 (0.18, 0.34) for mBP. Several phthalates and one benzophenone had lower reliability (ICC 0.20 to 0.29): mCPP, mBP, mibP, mCHP, mCMHP, and 4-OH-BP. All bisphenols measured were quite variable (ICC -0.11 to 0.01). We did not find substantial differences across ICCs when data were stratified by pregnancy status and race/ethnicity. Conclusion: The observed reliability was fair for monoethyl phthalate and poor for all others (ICC<0.4). A single measurement of non-persistent EDCs does not appear to reliably capture exposures over sensitive windows. To this end, longitudinal measurements are needed to ensure the validity of findings relative to these exposures and human fecundity and fertility.

### **P03.2770. Repeated Measures of Urinary Phthalates, Benzophenones and Bisphenol A in Relation to Incident Pregnancy Loss**

Anna Pollack

*Anna Z. Pollack<sup>1</sup>, Andrea Carmichael<sup>1</sup>, Jenna R. Krall<sup>1</sup>, Kurunthachalam Kannan<sup>2</sup>, Germaine Louis<sup>3</sup>*

- 1. Global and Community Health, George Mason University, Fairfax, VA, United States.*
- 2. Environmental Health Sciences, SUNY Albany/Wadsworth Center, Albany, NY, United States.*
- 3. College of Health and Human Services, George Mason University, Fairfax, VA, United States.*

**Abstract:** Background: Studies suggest nonpersistent endocrine disrupting chemicals such as phthalates, benzophenones and bisphenols may be associated with diminished fecundability, but little research has focused on their association with incident pregnancy loss. Methods: Using a prospective cohort design, 501 couples were recruited upon discontinuing contraception to try for pregnancy and followed daily until pregnant and through 7 weeks post-conception; 343 (68%) women with singleton pregnancies comprise the study cohort. Urine samples were collected upon enrollment (n=315; 92%), in the second (n=200), third (n=206), fourth (n=32) and sixth cycles (n=10). Bisphenols A, 5 benzophenones, and 13 phthalate metabolites were quantified using LC tandem MS. Generalized estimating equations estimated the relative risk (RR) of incident pregnancy loss for each chemical. Exposures were treated as continuous (log+1 transformed rescaled by standard deviation) and categorical (tertiles), adjusting for body mass index, race, serum cotinine, and age. Results: Incidence of pregnancy loss was 28% before 20 weeks' gestation. Lower risk of loss was noted for mOP (RR=0.69; 95% CI 0.54, 0.88), while mEHHP and mEOHP were suggestive of higher risk of loss. Relative to the first tertile, a higher risk of loss was observed for 2 benzophenones, for women in the second tertiles of BP-1 (RR=3.44; 95% CI 1.69, 7.01) and BP-3 (RR=2.02; 95% CI 1.02, 3.97), whereas a lower risk was observed for 4-OH-BP (RR=0.28; 95% CI 0.15, 0.53) and also for 2 phthalate metabolites: mCPP for 3rd vs. 1st (RR=0.35; 95% CI 0.13, 0.93) and mBP for 2nd vs. 1st (RR=0.45; 95% CI 0.23, 0.91). Conclusion: Benzophenones, as a class of chemicals, were suggestive of a possible association with pregnancy loss, and specifically BP- 1 and BP-3, which are believed to have estrogenic activity. Given their widespread use in personal care and sunscreen products and opposing pattern for 4-OH-BP, further investigation is needed.

### **P03.2780. Association between Radiofrequency Exposure during Pregnancy and Birth Outcomes in South Korea: Birth Cohort Study**

**Abstract:** Introduction: It is controversial whether RF (radiofrequency) exposure during pregnancy is hazardous to fetus. The aim of the present study is to elucidate the association between maternal RF exposure during pregnancy and birth outcomes. Method: Data from Mothers and Children's Environmental Health (MOCEH), a multicenter prospective birth cohort study in South Korea, was used in the present analysis. In 2011-2014, a total of 1751 pregnant women were recruited for the cohort, and we measured RF exposures of 244 women randomly selected from the cohort. RF exposure was measured via personal exposure meter (EME-Spy100®) for 24 hours at enrollment within 20 weeks of pregnancy. Each woman's RF exposure was calculated as sum of square of arithmetic mean for all measured levels divided by guidance level of each frequency band, and we calculated sums for total RF and mobile phone RF. We divided the women into 4 groups according to quartiles of RF exposure. At birth, weight, height, and gestational age were recorded. We used multiple regression model to examine associations between RF exposure and birth outcomes. We considered potential confounding factors such as maternal age, parity, smoking, alcohol consumption, education, income, marital status, child's sex, and birth area. Result: Birth weight and height of highest quartile group of total RF (-258.1g [95% CI=-485.6, -30.6] and -2.4cm [-3.8, -1.1], respectively) and mobile phone RF (-284.6g [-513.3, -56.0] and -2.0cm [-3.2, -0.7], respectively) were lower than those of lowest quartile groups. The results from models adjusting for gestational age were similar. Mean gestational age of highest quartile group of total RF was shorter than that of lowest quartile group (-4.2day [-9.9, 1.5]). Conclusion: We observed significant adverse associations between RF exposure and birth outcomes.

### **P03.2790. Effects of Prenatal Exposure to Phthalates on Neonatal Birth Weight: SHK Birth Cohort**

Yunhui Zhang

Yunhui Zhang<sup>1</sup>

*1. Department of Environmental Health, Fudan University, Shanghai, China.*

Abstract: Phthalates exposure were associated with lower birth weight. However, there's limited data on whether phthalates could affect birth weight directly or indirectly through gestational age and pregnancy syndrome. To evaluate the effects of prenatal exposure to phthalates on birth weight in neonates, 181 mother-newborn pairs were recruited from SHK birth cohort. Maternal urine samples were collected during the third trimester and measured for phthalate metabolites by the method of ESI-MS/MS. Structural equation models (SEM) were used to evaluate the direct effect of phthalate on birth weight controlling for maternal education, monthly income, nutritional supplements, infant gender and maternal weight gain per week. The potential indirect effects of phthalate exposure through gestational age on birth weight, as well as the potential indirect effect through pregnancy syndrome were also calculated by SEM method. After adjusting for all mediators, urinary phthalate levels were negatively associated with birth weight. An increasing ten-fold concentration of MEOHP and MEHHP would directly reduce birth weight in 124g and 107g, respectively. However, MBP had indirect effect on birth weight through gestational age, which caused an 85g reduction for every unit increase in log-transformed exposure. Both direct and indirect effects on birth weight were found in MMP and MEHP. The indirect effects of MMP and MEHP were mediated through gestational age and pregnancy syndrome. Totally, prenatal MMP and MEHP exposure were associated with 96g and 61g decreased birth weight, respectively. There's a negative association between prenatal phthalate exposure and birth weight in Chinese neonates. Besides direct pathway, phthalate exposures could affect birth weight through the mediating effects of gestational age and pregnancy syndrome.

### **P03.2800. Lactational Exposure to Phthalates: Preliminary Results from an Italian Cross-Sectional Study**

Elena Righi

*Elena Righi<sup>1</sup>, Guglielmina Fantuzzi<sup>1</sup>, Guerrino Predieri<sup>1</sup>, Diego Pinetti<sup>2</sup>, Francesca Faggioli<sup>1</sup>, Francesca Scelsa<sup>1</sup>, Annalisa Bargellini<sup>1</sup>*

**Abstract:** Background: Human exposure to phthalates, endocrine disruptors and reproductive toxicants, is ubiquitous because of their extensive use as plasticizers. Breast milk is the optimal source of nutrition for newborns, however, it can be a source of exposure to several environmental contaminants, including phthalates. Up to date limited information exists on lactational exposure to phthalates and their metabolites in Italy: The aim of this study, therefore, was to determine the levels of 8 different phthalates diesters and monoesters in breast milk of women living in Modena, Italy, and to investigate the relationship with women's diet and other habits. Methods: 130 women (mean age: 33; range: 19 - 45 years) provided a sample of breast milk (30-40 days postpartum) and filled in a questionnaire on personal data and on potential sources exposure to phthalates. After solid extraction, samples were analysed by triple Quad LC/MS Mass Spectrometry. Results: Phthalate diesters, due to their metabolic degradation, resulted almost undetectable. Phthalate monoesters appeared more widespread. Among them, mono-isononylphthalate (MiNP) was detected in 125 breast samples (mean:  $1.63 \pm 2.71$ ; range: 0.10 - 18.4  $\mu\text{g/l}$ ) and mono-ethylphthalate (MEP) in 106 samples (mean:  $2.35 \pm 7.36$ ; range: 0.04 - 69.0  $\mu\text{g/l}$ ). Their levels appeared higher in lactating women more frequently using cosmetics or consuming food and beverages preserved in plastic containers. Differences, however, were not statistically significant. Further, levels appeared well below the daily intake levels established by the European Food Safety Authority (EFSA). Conclusions: Although a number of phthalate monoesters were detected in maternal breast milk, their concentrations tended to be lower than those reported in other international studies and the values recommend by EFSA. Human milk represent a unique nourishment for infants in a crucial period of their life: its use should not be discouraged.

### **P03.2810. Relationship of Trimester-Specific Gestational Exposure to High Molecular Weight Phthalates with Neurodevelopment at 48 Months and Differences by Sex**

Libni Torres-Olascoaga

*Libni A. Torres-Olascoaga<sup>1</sup>, Marcela Tamayo y Ortiz<sup>1</sup>, Lourdes Schnaas<sup>2</sup>, Karen E. Peterson<sup>3</sup>, Martha M. Téllez-Rojo<sup>1</sup>, John Meeker<sup>4</sup>, Deborah Watkins<sup>4</sup>*

- 4. Department of Environmental Health Sciences, University of Michigan School of Public Health, Ann Arbor, MI, United States.*

**Abstract:** In-utero phthalate exposure has been associated with neurodevelopmental disorders, further modified by child's sex. Pregnant women are ubiquitously exposed to high molecular weight phthalates (HMWP) through diet. Nevertheless, trimester-specific susceptibility to exposure and effect modification by sex remain understudied. Our aim was to identify susceptible windows to the effects of gestational HMWP exposure and effect modification by sex, on 48-months neurodevelopment. We measured six HMWP metabolites (MBzP, MEHP, MEHHP, MEOHP, MECPP and MCP) in urine samples collected during each trimester from women in the Early Life Exposure in Mexico to Environmental Toxicants (ELEMENT) cohort (n=218). We measured children's motor (MI) and cognitive (GCI) abilities using McCarthy Scales of Children's Abilities (MSCA, lower scores indicated poorer performance). We used linear regression models to examine associations between trimester specific phthalate metabolites (individual,  $\Sigma$ DEHP,  $\Sigma$ HMWP) and MI or GCI scores. Phthalates were log-transformed and specific gravity corrected for all analyses. Models were adjusted for sex, gestational age at birth, breastfeeding, and maternal IQ. Effect modification was assessed stratifying by sex. Phthalate concentrations were similar across trimesters. All 1st and 2nd trimester phthalates were negatively associated with MI and GCI scores, while half of the 3rd trimester phthalates showed positive associations. Associations between 1st trimester phthalates and MI scores were the strongest and statistically significant (e.g. MECPP  $\beta$  = -2.6, 95% CI (-4.4, -0.8)). For GCI scores, the magnitude of negative associations were similar for the 1st and 2nd trimester phthalates, but not statistically significant. Overall, boys had stronger GCI and MI negative associations than girls. Our results suggest that HMWP exposure specifically during early pregnancy were strongly associated with poorer motor abilities at 48 months, particularly in boys.

### **P03.2820. Risk Factors for Asthma Symptoms in Children: ELSPAC-CZ Study**

Abstract: Asthma and asthma symptoms are increasingly prevalent in children worldwide. Wheezing and shortness of breath in the childhood are a heterogeneous condition, which may, in some cases, led to development of asthma. While the genetic predisposition is a clear risk factor for development of wheezing and or asthma, environmental factors could explain variation in prevalence rates. In this study, we temped to evaluated relevant protective and risk factors including socioeconomic determinants, indoor and outdoor environment, parental behaviour, diet, mode of childbirth and others. Where possible we have also studied the timing of the exposure. The Czech part of the European Longitudinal Study of Pregnancy and Childhood (ELSPAC-CZ) was established in the early nineties in the Czech Republic with recruitment of thousands of families and follow up until the 19 years of children, has been used to evaluate the factors. Multinomial logistic regression analysis with potential covariates was performed. We were able to determinate the risk factors for different phenotypes of childhood wheezing and shortness of breath.

### **P03.2830. Risk Factors for Childhood Asthma and Wheeze: Comparisons from an International Study**

**Abstract:** Background and objectives: International differences in childhood asthma prevalence have been reported with the environment suspected to play a role. We sought to investigate risk factors for asthma and wheeze and their consistency between countries. Methods: This was an international, cross-sectional study of children (6-13 years) living in an urban centre from Belarus, Canada, Republic of Georgia (Adjara), Republic of Macedonia, Poland, and Ukraine. History of physician-diagnosed asthma and wheeze in the past 12 months were ascertained from parent completed survey. Basic survey information was standardized but each site could include questions on additional potential risk factors. Multiple logistic regression was used to adjust for confounding. Results: In total, 12257 children participated (response rates: 26%-91%). Asthma prevalence was highest in Canada (12.6%) followed by Poland (10.3%) then the remaining sites (range: 1.0%-1.5%). Wheeze prevalence followed similar patterns but was higher than asthma (3.7% to 14.0%). In adjusted analyses using data from sites with the most comprehensive information (Canada, Poland, Macedonia), we found increased risk of asthma associated with antibiotic use, traditional medicine use, home mould or dampness, and family history of allergic conditions but a lower risk with being female ( $p < 0.05$ ). Similar results were seen when considering the outcome wheeze except that exposure to mice or pests increased the risk of wheeze and there was no association with home mould. There were some statistically significant interactions suggesting that the associations were not consistent between sites. Finally, when comparing no asthma or wheeze to those with wheeze without asthma as well as comparing no asthma or wheeze to those with asthma, risk factors were similar. Conclusions: Our findings suggest that in general, risk factors for asthma or wheeze are similar to what we expect but that some of these may be specific to certain locations.

### **P03.2840. Attention Deficit/Hyperactivity Disorder and Urinary Triclosan Levels in Children**

*3. National Yang-Ming University, Taipei, Taiwan.*

**Abstract:** Background: Attention Deficit/Hyperactivity Disorder (ADHD) on This study investigated the associations (i) between triclosan exposure and ADHD in children; and (ii) gender-based differences. Methods: A total of 453 children from the Childhood Environment and Allergic diseases Study (CEAS) cohort with urine samples were recruited. Urine triclosan levels were measured by UPLC-MS/MS and markers of oxidative stress (8-OHdG) were measured by ELISA at the age 3 and 6. Information on serum 8-OHdG levels and the development of ADHD was collected. The association between triclosan levels at different stages and (8-OHdG) levels, and ADHD were evaluated by multivariate linear regression and logistic regression after adjusting for potential confounders . The triclosan levels at age 3 were higher than those at age 6 (geometric mean 1.05 vs 0.37 ng/mL). Triclosan levels at age 3 positively correlated with serum 8-OHdG levels at age 3 and 6. Triclosan levels positively correlated with ADHD (per ln-unit:  $\beta=0.867$  KU/l (95%CI: 0.534-1.409)) Triclosan levels positively correlated with autism and developmental delay (per ln-unit:  $\beta=1.227$  KU/l (95%CI: 0.829-1.816); per ln-unit:  $\beta=1.028$  KU/l(95%CI: 0.777-1.362)), although this was not statistically significant. Conclusion: Triclosan levels might positively correlate with ADHD, autism, and developmental delay, though failed to reach statistically significance.

### **P03.2850. Childhood Nutrient Mixtures and Neurodevelopmental Outcomes among Children in Mexico City**

Ashley Malin

**Abstract:** Background: Adequate levels of beneficial nutrients are important for neurodevelopment. Although, nutrients are ingested in combination, considering nutrients as a mixture has not been studied with respect to health. Objective: To examine the impact of childhood nutrient mixtures on neurodevelopment. Methods: Participants included children in the Programming Research in Obesity, Growth Environment and Social Stress (PROGRESS) prospective birth cohort in Mexico City. We assessed child nutrition profiles among 329 children respectively by analyzing components of a food frequency questionnaire. Child neurodevelopmental outcomes at 4-6 years of age were measured using the McCarthy Scales of Children's Abilities (MSCA). Results: We conducted Weighted Quantile Sum regression analyses to calculate indices reflecting "good" and "poor" childhood nutrient mixtures. After adjusting for maternal education, socioeconomic status, the Home Observation for Measurement of the Environment score at 24-months postpartum and total caloric intake, the poor nutrition index significantly predicted lower scores on memory, quantitative and perceptual MSCA scales (Perceptual B = -1.88, at 95% CI = -3.17, -0.58), while the good nutrition index predicted higher scores on the perceptual scale (Perceptual B = 0.81, at 95% CI = 0.01, 1.61). In the poor nutrition index, higher sodium and saturated fat consumption and lower monounsaturated fat and protein consumption had relatively high weights when predicting poorer scores on various MSCA scales. In the good nutrition index, higher monounsaturated fat and calcium had relatively high weights within the mixture when predicting more favorable perceptual performance. Conclusions: Using a novel statistical method we found that childhood consumption of a mixture of beneficial nutrients had favorable effects on neurodevelopment. Furthermore, certain nutrients appeared to be more important for the development of certain skills and abilities than others were.

### **P03.2860. Proximity to Floricultural Production and Childhood Neuropsychological Function**

Marnie Hazlehurst

*Elizabeth Friedman<sup>1</sup>, Marnie Hazlehurst<sup>1</sup>, Catherine Karr<sup>1</sup>, Jose R. Suarez-Lopez<sup>2</sup>*

*2. University of California San Diego, La Jolla, CA, United States.*

**Abstract:** Background: Pesticide exposure during early childhood may be a risk factor for a range of pediatric neurologic deficits. Chronic exposure to these pesticides among children can occur due to drift from or direct contact with pesticide-treated areas. Methods: We examined 4-9 year-old participants who lived in agricultural communities in Ecuador (The ESPINA study). Two exposures were calculated: residential distance from the nearest flower plantation perimeter and total area of flower plantations within 200m of the home. Five neurodevelopment domains were assessed (NEPSY-2): Attention/inhibitory control, memory/learning, language, sensorimotor, and visuospatial processing. Linear and logistic regression models were adjusted for child's age, sex, race, height-for-age z-score, hemoglobin, mother's education, and cohabitation with a floricultural worker. Results: The 307 children in this study (mean age 6.6 years, 51% boys) lived on average 446m (SD 344) from a flower plantation. Mean (SD) neurobehavioral domain scores ranged from 6.6 (2.4) to 9.9 (3.3). For a 100m increase in distance between homes and plantations, there was better performance in the language domain by 0.09 units (95% CI: 0.00, 0.17). Children living within 185m of a plantation (quartile 1) had increased odds of clinically significant "low" scores in the language (OR [95% CI]: 2.4 [1.1, 5.5]) and memory/learning (4.8 [1.3, 19.0]) domains compared to children living >610m (quartile 4) from treated areas. Children with >3061m<sup>2</sup> (tertile 3 of non-zero values) of plantation area within 200m of their homes, compared to those with 0m<sup>2</sup> of plantation area, had increased odds for low memory/learning scores (4.3 [1.30, 14.1]). Conclusions: Residential proximity to floriculture plantations was associated with adverse neuropsychological performance in the domains of language and memory/learning among children, highlighting the importance of reducing pesticide exposures for children living near plantations.

### **P03.2870. Verbal and Learning Memory in Schoolchildren Exposed to Manganese in Mexico**

**Abstract:** Manganese (Mn) is an essential nutrient for cellular function, however, in high concentrations is neurotoxic. The inhalatory via is the most faster to transfer Mn to brain. Mn affects the development and function to the basal ganglia and frontal lobes. Environmental exposure to Mn has been associated with cognitive effects in children. Mexico has one the ten largest Mn deposit in the world. located northwest of state of Hidalgo. The aim to this study was asses the effect of environmental exposure to Mn on verbal memory and learning in schoolchildren from 7 to 11 years old residents of this area. Two cross sectional study were conducted (2006 and 2013). 268 schoolchildren were included, 146 children from the mining area and 122 from the non-mining area. The CAVLT-2 was used to assess verbal memory and learning. In addition, hair Mn levels (MnH) were determined using atomic absorption spectrophotometry. Linear regression models were constructed to estimate the association between MnH levels and CAVLT-2 scores, the models were adjusted by lead, hemoglobin, children age and sex, and maternal IQ. Children in the mining area on average had higher concentrations of MnH (5.12 µg/g) compared to schoolchildren in the non-mining area (0.56 µg/g). CAVLT-2 scores were significantly higher in children in the non-mining area compared to schoolchildren in the mining area. The levels of MnH were associated with a significant decrease in the scores of the trials 1 - 5 of the learning curve, level of learning, interference trial, immediate recall, delayed recall, immediate memory span and recognition accuracy. The main finding of this study was the negative association between MnH levels and verbal short- and long-term memory and learning abilities in schoolchildren exposure to Mn.

**P03.2880. Associations of Acetylcholinesterase Activity with Depression and Anxiety Symptoms among Adolescents Growing Up near Pesticide Spray Sites**

Jose Suarez-Lopez

*Jose R. Suarez-Lopez<sup>1</sup>, Naomi R. Hood<sup>1</sup>, Jose Suarez-Torres<sup>2</sup>, Dolores M. Lopez-Paredes<sup>2</sup>*

*1. Family Medicine and Public Health, University of California San Diego, La Jolla, CA, United States.*

*2. Fundacion Cimas del Ecuador, Quito, Ecuador.*

**Abstract:** Background: Self-reports of pesticide exposures have been associated with increased depression and anxiety symptoms among adult agricultural workers; research among children and adolescents is lacking and no studies have described these associations using biomarkers of exposure. Methods: We estimated the associations among 516 adolescents (ages 12-19y) in 2016 living in floricultural communities in Ecuador: The ESPINA study. Children's acetylcholinesterase (AChE) activity (lower values reflect greater organophosphate or carbamate pesticide exposure) was measured in a finger-stick sample. Anxiety and depression symptoms were assessed using the CDI-2 and MASC-2 (greater t-scores reflect greater internalizing symptoms). Models adjusted for age, gender, hemoglobin and anthropometric measures. Results: 51% of participants were female; the median age was 14.4y. The mean (SD) of the following parameters were: AChE 3.7 U/mL (0.55), depression t-score 53.0 (9.4) and anxiety t-score: 57.6 (9.8). AChE activity was inversely related to depression score (difference per SD decrease of AChE [ $\beta$ ]: 0.87 units [95%CI: -0.18, 1.91]); the OR for moderately elevated depression score (>55) per SD decrease of AChE was 1.28 [1.00, 1.62]. The association was stronger among children <14.4y ( $\beta$ : 2.00 units [0.22, 3.78]; OR: 1.41 [1.02, 1.96]) than among older adolescents ( $\beta$ : 0.28 units [-1.03, 1.60], OR: 1.17 [0.85, 1.62]). These associations were strengthened after accounting for 2008 AChE values. Among children <14.4y, the associations were stronger in girls (OR: 1.91 [1.00, 3.65]) than boys (OR: 0.90 [0.40, 2.03]). No associations were observed with anxiety scores. Discussion: This is the first study to describe associations between a biomarker of pesticide exposure and depression symptoms, in one of the largest studies of its kind. Cholinesterase inhibition may affect the mood towards depression of non-agricultural-worker adolescents, particularly among girls during early adolescence.

### P03. Adult Health Effects of Environmental Exposures 3

#### **P03.2890. Investigation of Spatial Clusters of Chronic Cardiopulmonary Diseases in New York City**

Bian Liu

*Bian Liu<sup>1</sup>, Yan Li<sup>3</sup>, Li Niu<sup>2</sup>, Shelley H. Liu<sup>1</sup>*

*1. Population Health Science and Policy, Icahn School of Medicine at Mount Sinai, NYC, NY, United States.*

*2. Department of Psychology, Fordham University, New York, NY, United States.*

*3. The New York Academy of Medicine, Center for Health Innovation, New York, NY, United States.*

**Abstract:** We aim to identify localized spatial clusters for four common cardiopulmonary diseases: Asthma, chronic obstructive pulmonary disease (COPD), coronary heart disease (CHD), and stroke in New York City (NYC). We used the 500 Cities data from the Centers for Disease Control and Prevention, which provide prevalence estimates for chronic diseases, health behavioral and prevention measures at the census tract level for the 500 largest cities in the United States. Our analyses focused on NYC (n=2101 tracts) with additional sociodemographic data from the Census and pollution data from the Environmental Protection Agency. We first conducted a normal scan statistic (SatScan V9.5) using the crude prevalence with a weight adjustment based on the standard error of the prevalence. We also conducted a multivariate regression model using the four health outcomes as the dependent variables, with covariates being sociodemographic, unhealthy behavior and health care access, and pollution factors. Residuals from the model were used in SatScan for spatial cluster detection. Using the crude prevalence, we identified 3 and 2 high risk clusters for asthma and COPD, respectively. Using residuals, we found different cluster patterns. Comparisons of cluster locations and sizes showed a high residual risk cluster centered at 40.82N/73.96W with a 3.50-km radius (~ 100 tracts) in the west Harlem neighborhood for COPD, CHD, and stroke. The high residual cluster for asthma was centered at 40.64N/73.92W with an 11.54-km radius (n=1044 tracts), covering mostly Brooklyn and parts of Queens neighborhoods. The asthma cluster also overlapped with two small high risk clusters (<10 tracts) for COPD and stroke. Geographic variations of high and low risk clusters for chronic cardiopulmonary diseases exist in NYC even after adjusting for the usual suspected factors. The identified common clusters suggest intervention opportunities that may simultaneously benefit multiple chronic disease health outcomes.

**Abstract:** Purpose: Excess cancer has been reported among populations exposed to the 9/11 World Trade Center (WTC) attacks. This study explores the utility of the WTC Health Program (WTC-HP) General Responder (GR) monitoring data for analysis of head and neck cancer (HNC) risk factors. Methods: The WTC-HP provides medical monitoring and treatment for eligible WTC workers and volunteers. Monitoring visits include surveys about health and related exposures. Data from consenting participants are managed by the GR Data Center. We used a nested case-control design. HNC cases were selected using ICO-3 coding. Controls (8:1) were selected by risk-set sampling based on case diagnosis age and date, then matched within risk sets on sex and race/ethnicity. Distribution of WTC exposure, occupational groups prior to 9/11 (law enforcement(LE), construction, other), alcohol consumption (mod/heavy/former heavy vs. non-/occasional drinkers), and smoking status at first visit was assessed using conditional logistic regression. Results: In this preliminary analysis (65 cases; 555 controls), positive associations were observed between HNC and heavier alcohol use (OR=1.7; 95% CI: 0.9, 3.2) and occupation in law enforcement (OR LE vs. other = 1.9, 95% CI: 0.95, 3.8). BMI (body mass index) was significantly inversely associated with HNC (OR obese vs. normal =0.3, 95% CI: 0.1, 0.7). The distribution of WTC exposure and smoking status was similar among cases and controls. Finally, cases enrolled in the WTC-HP before and after their HNC diagnosis did not differ in respect to any of the risk factors considered. Conclusions: The weak associations with HNC were surprising and may indicate: risk factor misclassification or underreporting; unmeasured causal risk factor(s) (e.g. HPV infection); or inadequate power. Future analyses will include additional cases and refined risk factor assessments to examine the value of WTC-HP data for epidemiologic analyses of tobacco- and alcohol-related cancers.

**Abstract:** Introduction: Sibate is a small town (38,000 inhabitants) nearby Colombia's capital, Bogotá. A water reservoir, el Muña, is located south-west of the town. Residents from Sibate report that during the 1970s and 1980s, parcels were filled with asbestos containing materials (ACM), to push out the heavily polluted waters of the reservoir from the urban area and create new land for urban development. Aims: The aims of this study are to confirm the existence of the landfills, and determine the presence of ACM in the soils of the town. Methods: Satellite images and topographic maps from different years were combined within a geographic information system to identify changes in height that could determine areas where lands were possibly filled. In some of these areas, soil samples were collected and analyzed by PLM following ASTM D7521-16 method and EPA' soil screening guidelines. Results: Ten potential landfill zones were identified, with a total area of approximately 30,000 m<sup>2</sup>. In three of these zones, four soil perforations were made. A grey layer of friable asbestos was found in 3 of the 4 perforations at different depths (35-110cm). All six samples of the grey layer of friable asbestos analyzed had a chrysotile content ranging between 5 to 10%, and one sample had 2% crocidolite. Non-friable asbestos materials were also analyzed, and asbestos content ranged between 2-10% for chrysotile, and one sample had 2% crocidolite. Current land uses of these zones include two soccer fields, an athletic track, and a school. Discussion: An important potential source of asbestos exposure has been confirmed in the town. This is a public health problem with potential and concerning implications. Further work will be conducted to determine the boundaries and characteristics of the landfills, as well as the risk of asbestos exposure at the surface. The health authorities of the municipality have been informed about the findings, and are currently working in a risk management strategy.

**P03.2920. Exploratory Descriptive Analysis: Incidence of Neoplasia and Congenital Malformations in Tremembe City - Sao Paulo - Brazil (1998-2017)**

Paulo Paz de Lima

Abstract: The municipality of Tremembé is located in the Paraíba Valley region, in the State of São Paulo- Brazil. It has a population of 40,984 inhabitants. It houses an agricultural production mainly represented by the cultivation of rice by flooding technique and a chemical additives factory. The present study aims to analyze the incidence of neoplasms and congenital malformations in the city of Tremembé / SP; to analyze the health data of the municipality of Tremembé, referring to the neoplasias and the congenital malformations, comparing with the data of neighboring municipalities like Taubaté, Pindamonhangaba and Aguas de São Pedro, belonging to the same region of study. This is a cross-sectional descriptive study on the incidence of neoplasias and congenital malformations, based on data collected from the Health System of the Ministry of Health in 4 municipalities in the State of São Paulo / SP. The results point to a higher incidence of neoplasms and congenital malformations in the Tremembé region. The results indicate the need for analysis between the exposure of the population of the municipality of Tremembé to the chemicals harmful to health used in industry and local agriculture and the number of cases of congenital malformations.

### **P03.2930. Sleep Quality and Duration and the Risk of Breast Cancer in a Population-Based Study**

**Abstract:** Background: The association between sleep and breast cancer is uncertain. This study was to prospectively investigate the joint effects of the quality and duration of sleep on the development of breast cancer. Methods: 90,881 women aged more than 20 years were selected from a prospective cohort in Taiwan. Self-administered questionnaires were used to collect information on duration and quality of sleep as well as potential confounders. Incident cases of breast cancer were self-reported in subsequent medical examinations. Sleep score was constructed to reflect the participants' sleep profiles with regard to both duration and quality via additive model. The proportional Cox regression method was used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs). Results: 292 individuals reported incident cases of breast cancer at follow-up. The sleep score was associated with the risk of breast cancer with exposure-response trend ( $p < 0.001$ ). Every five-unit increment of sleep score was associated with an 8% decreased risk of breast cancer after adjusting for potential confounders. Higher risk of breast cancer were observed in participants in the lowest quartile (HR: 1.52; 95% CI: 1.07-2.14) and second lowest quartile (HR: 1.45; 95% CI: 1.05-2.02) of sleep scores compared with those in the highest quartile. Conclusion: A poor sleep profile is associated with an increased risk of breast cancer. Our findings suggest that improving sleep behavior by considering both duration and quality can be an important approach in the prevention of breast cancer.

### **P03.2940. Serum Concentrations of Polybrominated Diphenyl Ethers (PBDEs) and Breast Cancer Risk in Young Women: Results from the Ontario Environment and Health Study**

**Abstract:** Polybrominated diphenyl ethers (PBDEs) are brominated flame retardants commonly used in a wide range of household products and electronic devices. Some PBDE congeners have endocrine-disrupting properties, suggesting a potential role in the development of hormonally-related cancers. This is the first study to investigate serum PBDE levels in relation to breast cancer diagnosed in women under 45 years of age. Serum samples were collected from 305 incident breast cancer cases (284 pre-menopausal), identified in the Ontario Cancer Registry between 2012 and 2015, and 144 controls. Gas chromatography/electron ionization-mass spectrometry was used to quantify 8 congeners (ng/mL): BDE-28, BDE-47, BDE-85, BDE-99, BDE-100, BDE-153, BDE-154, BDE-183. Samples in which congeners were not detected or had concentrations below the method detection limit were considered unexposed. For each congener odds ratios (OR) and their 95% confidence intervals were estimated using logistic regression, with adjustment for age, serum lipids, body-mass index 2 years earlier, parity, and date of sample collection. Detection prevalence for each congener was as follows: BDE-47 (52.8%), BDE-153 (19.4%), BDE-99 (11.8%), BDE-100 (9.8%), BDE-28 (4.5%), BDE-183 (4.5%), BDE-154 (1.8%). BDE-47 detection was positively associated with breast cancer status (OR=1.65, 95% CI: 0.99-2.74), but this relationship was significant only in pre-menopausal women (OR=1.73, 1.02-2.94). Suggestive associations were also observed for BDE-153 (OR=1.63, 0.89-2.98) and several related congeners. Combined exposure to BDE-153, -154, and -183 was significantly associated with breast cancer risk (OR=1.98, 1.11-3.56; pre-menopausal: OR=2.19, 1.17-4.11). Non-linear relationships with BDE concentrations were evaluated using smoothing splines, but no significant associations ( $p < 0.05$ ) with case status were observed. Our preliminary findings suggest a possible association between serum PBDE levels and risk of breast cancer in young women.

### **P03.2950. Hexavalent Chromium and Stomach Cancer: A Systematic Review and Meta-Analysis**

Mina Suh

*Mina Suh<sup>1</sup>, Daniele Wikoff<sup>1</sup>, Seneca Harvey<sup>1</sup>, Liz Mittal<sup>1</sup>, Loren Lipworth<sup>2</sup>, Michael Goodman<sup>3</sup>, Alea Goodmanson<sup>1</sup>, Caroline L. Ring<sup>1</sup>, Annette Rohr<sup>4</sup>, Deborah Proctor<sup>1</sup>*

Abstract: Hexavalent chromium [Cr(VI)] is a carcinogen known to cause lung cancer in workers of certain industries. An association with stomach cancer is uncertain. Systematic review and meta-analyses were conducted to evaluate the association between Cr(VI) and risk of stomach cancer. Documented in the protocol (PROSPERO #CRD4201605162), PubMed, Embase®, and hand searching were used to identify studies. Eligibility criteria included studies of: 1) animals with ingestion exposures to Cr(VI) (n=3); 2) non-occupational populations with ingestion exposures to Cr(VI) (n=6); 3) workers in occupations recognized as having exposure to Cr(VI) (n=50; 3 case-control, 47 cohort). Critical appraisal and qualitative integration were carried out using the National Toxicology Program's Office of Health Assessment and Translation approach; 9 meta-analyses were conducted based on the occupational data. Of the animal studies, one study with low risk of bias was negative, one study with high risk of bias reported forestomach tumors but showed poor internal validity; another study was negative. Non-occupational data were ecologic studies with conflicting results; they were unsuitable for meta-analysis. Critical appraisal of the occupational data with regards to internal validity showed that most studies were categorized as Tier 3 (n=37) or Tier 2 (n=12) with high or probably high risk of bias observed for confounding and exposure characterization domains; overall confidence in this body of evidence was moderate. Meta-analyses consistently showed no significantly increased stomach cancer risk. The overall meta-relative risk (meta RR, excluding Tier 3 studies) for stomach cancer was 1.03 (95%CI 0.84-1.26). Notably, for studies of workers (n=22) from industries with clear evidence of elevated lung cancer due to Cr(VI) exposure, meta-RR was not significantly elevated (1.07, 95%CI 0.89-1.27). Combining the streams of evidence, a lack of association between Cr(VI) and stomach cancer is shown.

**Abstract:** Objectives: Dioxins, Group 1 carcinogens, are emitted by industrial combustion processes and suspected to increase breast cancer (BC) risk through receptor-mediated pathways. We aimed to estimate BC risk associated with airborne dioxin exposure, using geographic information system (GIS) methods and historical exposure data. Methods: We designed a case-control study (429 BC cases diagnosed between 1990 and 2008, matched to 716 controls) nested within the E3N (Etude Epidémiologique auprès de femmes de la Mutuelle Générale de l'Education Nationale) cohort. Airborne dioxin exposure was assessed using a GIS-based metric including participants' residential history, technical characteristics of 222 dioxin sources, residential proximity to dioxin sources, exposure duration and wind direction. We first estimated odds ratios (OR) and 95% confidence intervals (CI) associated with quintiles of cumulative exposure using logistic regression. We then estimated effects of annual exposure on BC risk according to time prior to diagnosis using a flexible time-dependent weight function. Results: We observed no increased risks of BC for higher dioxin exposure levels overall and according to hormone-receptor status. We however observed statistically significant ORs for Q2 versus Q1 overall (1.61, 95% CI: 1.04-2.49) and for estrogen-receptor (ER) positive BC (1.95, 95% CI: 1.08-3.51). ORs associated with an increase of 0.1 µg-TEQ/m<sup>2</sup> in the annual intensity of exposure in each year before diagnosis were all not statistically different from one, whatever the timing of exposure. Conclusions: No association was observed between airborne dioxin exposure and BC risk in our study. Suggested increased risks for low exposure levels for overall and ER-positive BC might be compatible with non-monotonic dose-response relationship. Confirmation of our findings is required. Our study may provide an alternative in absence of ambient dioxin monitoring and may allow assessing exposure to other pollutants.

**P03.2980. DNA Methylation Mediates Effects of Smoking on Gene Expression in Lung Cancer Tissues**

Wen-Chi Pan

*Yu-Ting Chan<sup>1</sup>, Shu-Hsien Cho<sup>2</sup>, Yen-Tsung Huang<sup>2</sup>, Wen-Chi Pan<sup>1</sup>*

*1. Institute of Environmental and Occupational Health Sciences, National Yang-Ming University, Taipei, Taiwan.*

*2. Institute of Statistical Science, Academia Sinica, Taipei, Taiwan.*

**Abstract:** Background: Smoking is a well-known risk factor contributes to the development of lung cancer globally, and DNA methylation could serve a potential underlying mechanism. Previous evidences were mostly based on the peripheral blood samples to support this hypothesis. However, only limited studies focused on the interplay between smoking and DNA methylation on lung cancer etiology. Objective: To assess the association of smoking with gene expression in lung cancer tissues, and evaluate the mediation roles of DNA methylation on smoking-lung cancer pathway. Materials and Methods: We extract the information of lung cancer participants regarding their smoking intensity (pack-year), DNA methylation, gene expression, and demographic from The Cancer Genome Atlas (TCGA) (1991-2013). The linear regression models were applied to assess the association for smoking, DNA methylation, and gene expression adjusting for the potential confounders. An external dataset (GSE66836) was used for the further validation. We applied the causal mediation analysis to quantify the natural indirect effect (NIE) for the externally validated CpG sites. Results: A total of 616 lung cancer patients including lung adenocarcinoma (n=306) and squamous cell cancer (n=310) were identified in TCGA. We found that 4,332 CpG sites were statistically associated with smoking and gene expression in TCGA dataset (p-value <0.05). Among those locus, a total of 6 CpG sites located in 5 different genes (PRMD16, CDK6, NETO2, CD109, and FAM171B) imposed statistically significant mediation effects (i.e. NIE) on smoking-gene expression association (p-value <0.05) in external validation dataset, with proportion of mediation greater than 100%. Conclusions: DNA methylation plays an important role on how smoking affects gene expression in lung cancer tissues. Future studies could further evaluate other mechanisms linking smoking and lung cancer beyond the scope of DNA methylation.

### **P03.2990. Polymorphisms of Genes Related to Nucleotide Excision Repair and Cell Cycle Pathways, Arsenic Exposure, and Bladder Cancer**

Ya-Yun Cheng

Ya-Yun Cheng<sup>1</sup>, How-Ran Guo<sup>1</sup>

*1. Department of Environmental and Occupational Health, National Cheng Kung University, Tainan, Taiwan.*

**Abstract:** Arsenic is a human carcinogen, and previous studies have demonstrated that it may act through the inhibition of DNA repair mechanisms and the disruption of mitosis to induce apoptosis and centrosome aneuploidy. DNA adducts caused by chemical carcinogens are repaired primarily through the nucleotide excision repair (NER) pathway. Aneuploidy is a common phenomenon regulated by Aurora A (STK15) in cancer cells. The tumor suppressor p53 is an important regulator of the cell cycle and apoptosis and is frequently inactivated in human cancers. We conducted a study in southwestern Taiwan to evaluate whether genetic polymorphisms in the NER (ERCC1 Asn118Asn, XPD Lys751Gln, and XPC Ala499Val) and cell cycle (functional STK15 Phe311Ile and p53 Pro72Arg) pathways have associations with bladder cancers related to arsenic exposure. We recruited 104 bladder cancer patients and 265 cancer-free controls. A questionnaire was used to collect data on demographics, life style, and environmental factors. Genotypes were determined using PCR-RFLP. The arsenic level in drinking water of each participant was assessed on the basis of the address. We found that older age, male sex, lower education level, smoking, and arsenic exposure (with dose-response relationship,  $p < 0.05$  for test for trend) were risk factors of bladder cancer. Among the NER pathway polymorphisms, we found ERCC1 Asn118Asn was associated with bladder cancer (odds ratio [OR] = 5.4; 95% confidence interval [CI]: 2.7-11.0) after adjusting for the arsenic level in drinking water and other risk factors. Among the cell cycle pathway polymorphisms, we found STK15 Phe311Ile (T>A) mutant type (AA) (OR=2.7; 95% CI: 1.1-7.1) was associated with a higher risk of bladder cancer.

**P03.3000. Herbal Medicine Containing Aristolochic Acid and the Risk of Hepatocellular Carcinoma in Patients with Hepatitis C Virus Infection: A Nationwide Population-Based Cohort Study in Taiwan**

Pau-Chung Chen

*Wen-Chao Ho<sup>4</sup>, Chi-Jen Chen<sup>2</sup>, Yao-Hsu Yang<sup>3</sup>, Meng-Hung Lin<sup>3</sup>, Chuan-Pin Lee<sup>3</sup>, Yu-Tse Tsan<sup>5</sup>, Ming-Nan Lai<sup>6</sup>, Hsiao-Yu Yang<sup>1</sup>, Pau-Chung Chen<sup>1</sup>*

**Abstract:** Background: The purpose of this study was to investigate the association between the use of herbal medicine containing aristolochic acid (AA) and the risk of hepatocellular carcinoma (HCC) among hepatitis C virus (HCV)-infected patients. Methods and Findings: We conducted a nationwide population-based cohort study on patients older than 18 years who had a diagnosis of HCV infection between January 1, 1997 and December 31, 2010. A total of 223,467 HCV-infected patients were identified by using the National Health Insurance Research Database in Taiwan. The use of herbal medicine containing AA was identified between 1997 and 2003 and had visited traditional Chinese medicine clinics before one year before the diagnosis of HCC or the censor dates. Each patient was individually tracked from 1997 to 2013 to identify incident cases of HCC since 1999. There were 25,502 HCCs during the follow-up period of 3,052,132 person-years and the overall incidence rate was 835.5 HCCs per 100,000 person-years. The adjusted hazard ratios (HRs) were 1.21 (95% confidence interval [CI], 1.18 to 1.24), 1.48 (95% CI, 1.37 to 1.59), 1.50 (95% CI, 1.34 to 1.68), and 1.88 (95% CI, 1.61 to 2.19) for estimated AA of 1 to 250, 251 to 500, 501 to 1,000, and more than 1,000 mg, respectively, relative to no AA exposure. Conclusions: Our study suggests that AA exposure in association with HCV plays an important role in the carcinogenesis of HCC.

### **P03.3010. Residential Proximity to Animal Feeding Operations and Cancer Risk in the Agricultural Health Study**

Jared Fisher

*Jared A. Fisher<sup>1</sup>, Laura Beane Freeman<sup>1</sup>, Jonathan Hofmann<sup>1</sup>, Aaron Blair<sup>1</sup>, Christine Parks<sup>2</sup>, Peter S. Thorne<sup>3</sup>, Mary H. Ward<sup>1</sup>, Rena R. Jones<sup>1</sup>*

- 3. Department of Occupational and Environmental Health, University of Iowa College of Public Health, Iowa City, IA, United States.*

**Abstract:** Background: Concentrated animal feeding operations (AFOs) are major sources of hazardous emissions into the surrounding environment, but few studies have investigated cancer risk associated with living near intensive animal agriculture. Methods: We evaluated the association between residential proximity to AFOs and cancer risk among licensed pesticide applicators (mostly male farmers) in the Agricultural Health Study cohort. We linked enrollment (1993-1997) addresses for 32,674 participants in Iowa to a statewide database of permitted AFOs that included animal counts standardized by animal size and manure production (animal units; AUs). We created metrics to reflect exposure proximity and intensity, enumerating AFOs and animal density (quartiles of AUs) within 2 and 5km of residences. Cox regression was used to estimate associations (hazard ratio, HR; 95% confidence interval, 95%CI) with incident cancer for major tumor sites, adjusting for demographic and farming-related factors (e.g., raising animals and occupational pesticide exposure). Results: There were 4,741 incident cancers from 1993-2015. We observed increased risk for non-Hodgkin lymphoma among those residing within 5km of at least one AFO (HR=1.9; 95%CI=1.3-3.0), but without a statistically significant trend across AU quartiles (ptrend=0.31). Prostate cancer risk was significantly elevated in the highest AU quartile (HR=1.4; 95%CI=1.1-1.6; ptrend=0.01). Lung cancer associations showed an inverse, monotonic trend with increasing AUs (HRQ4=0.74; 95%CI=0.5-1.1; ptrend=0.04). Adjustment for contact with animals and occupational use of pesticides previously associated with these cancers did not change the results, and patterns were similar for exposures within 2km. We found no associations for other cancers. Conclusions: Our findings suggest that residential proximity to AFOs may influence risk of cancer at certain sites, even after consideration of animal contact and occupational exposure to pesticides.

**Abstract:** Background: The natural light/dark cycle is the most important environmental cue for entrainment of circadian rhythms. Residents in the western vs. eastern portion of a time zone receive less light exposure in the morning and greater light exposure at night. This differential exposure to light, despite similar work and social hours, may lead to chronic misalignment of the circadian system, and impact breast cancer risk through DNA damage and endocrine disruption mechanisms. Shift work and western time zone position have been associated with breast cancer. Our aim was to prospectively examine the association between residential position in a time zone and breast cancer risk. Methods: We analyzed data from 112,663 participants (1989-2013) in the Nurses' Health Study II, a nationwide prospective cohort of US female nurses. Distance from time zone meridian was estimated using geocoded residential addresses updated throughout follow-up in a geographic information system. Self-reported breast cancer was confirmed from medical records. Estrogen receptor (ER) and progesterone receptor (PR) status were determined via immunohistochemical analysis of tissue microarrays, pathology reports, or medical records. Time-varying Cox regression models were used to calculate hazard ratios (HRs) and 95% confidence intervals (CIs) adjusted for numerous breast cancer risk factors. Results: There was no association between residential distance from time zone meridian and invasive breast cancer risk overall (n=3,950 cases; adjusted HR per 5-degree increase in longitude moving east to west within a time zone 0.96, 95% CI 0.93, 1.00) or with breast cancers defined by ER/PR status. This association was not modified by shift work, chronotype, outdoor light at night, time zone, residential mobility, or menopausal status. Conclusions: Residential position in a time zone does not appear to be associated with breast cancer risk.

### **P03.3030. Thyroid Cancer Under 19 at the Accident in Fukushima: The Sixth Report - the 2nd and 3rd Round Screening Results**

*4. Department of Epidemiology, OkayamaHarvard T.H. Chan School of Public Health, Boston, MA, United States.*

**Abstract:** Background/Aim After the nuclear power plant accident in Mar 2011, Fukushima Prefecture began thyroid screening (1st round) for all children ages  $\leq 18$  years at the accident until Mar 2014, the 2nd round from Apr 2014 to Mar 2016, and the 3rd round from Apr 2016 to Mar 2017. The data were as of Dec 31, 2018. Methods From report on the 3rd round, Fukushima Prefecture divided the prefecture into 4 areas: (a) Nearest area (i.e., the most contaminated); (b) Middle area; (c) Seafront area excluding the Nearest area; and (d) Aizu area (the West area; the least contaminated). After resequencing the 1st and the 2nd results into the 4 areas, we compared them externally and internally. For an external comparison, we estimated standardized incidence ratios (SIRs) for thyroid cancer, compared with the annual incidence among ages 0-24 in Japan. In the 2nd and 3rd rounds, length of time elapsed between the accident and timing of screening became more comparable across different areas in Fukushima Prefecture. Results Seventy-one thyroid cancer cases were detected in the 2nd, and 10 cases were detected in the 3rd (still in the process of counting). Among the 81, 59 were operated and confirmed histologically (papillary cancer except one). All except three underwent screening of the round before. Sixty-three (81%) of the 78 cases did not have any nodules in the previous round. SIRs (95% confidence interval: Number of cases) for each area were (a) 60.5 (35.2-96.8: 17), (b) 38.9 (27.7-53.2: 39), (c) 25.8 (12.4-47.5: 10), and (d) 22.9 (7.4-53.4: 5) in the 2nd round, and (a) 22.9 (6.3-58.8: 4), and (b) 7.5 (2.7-16.2: 6) in the 3rd ((c) and (d) were 0 cases) under the assumption that no cancer cases exist in the rest of examinees. Dose (distance from the plant as proxy)-response (excess thyroid cancer incidence) was observed about threefold in internal comparison. Conclusions High SIRs and dose-response in the 2nd and the 3rd rounds were unlikely explained by a "screening effect" alone.

### **P03.3040. Prevalence of Breast Benign Findings in Women Residing in an Area of Chronic Exposure to HCH, DDT and Dioxin**

Nataly de Figueiredo

*2. Public Health Institute, Federal University of Rio de Janeiro, Rio de Janeiro, Rio de Janeiro, Brazil.*

Abstract: Organochlorine compounds are known for their hormone-active properties, with emphasis on their performance as environmental estrogens. It is discussed whether its prolonged action in the body could lead to lesions in the breast tissue associated with the proliferative effect of estrogens on the epithelial cells of the breast. This study aimed to estimate the occurrence of benign breast diseases (BBD) in women living in an area with a history of chronic exposure to Hexachloroexan, DDT and Dioxin. A cross - sectional study was carried out in Cidade dos Meninos (CM), a district located in the municipality of Duque de Caxias (MDC), State of Rio de Janeiro - Brazil. Women 35 years of age or older residing on the site were eligible for the study. Mammography and / or ultrasound examinations were performed for investigation and categorization according to the Birads classification. We compared the mammographic findings classified in categories 2, 3 and 4 with the results classified in category 1 (without findings). The results obtained in this study population were compared with the results of the Municipality of Duque de Caxias, which were obtained through the SISMAMA / DATASUS data from July 2014 to July 2015, equivalent to the period of data collection in the exposed population . For this comparison the ratios of ratios and 95% confidence interval (95% CI) were used. A total of 111 women aged 35-79 years (M - 52 years; SD - 10.6) participated in the study. The prevalence of BBD was higher in the study population compared to MDC (OR = 1.49 - 95% CI 1.305 - 1.699). The results of the comparison of the study population with the municipality of Duque de Caxias suggest a higher prevalence of DBM in the studied population, corroborating with the hypothesis of association of the exposure to the occurrence of proliferative DBM.

### **P03.3050. Gene-Environmental Interaction among Women with Benign Breast Disease in Brazil**

Ilce Silva

*Ilce F. Silva<sup>1</sup>, Rafaela L. Senra<sup>3</sup>, Viviane F. Esteves<sup>2</sup>, Marla P. Schilling<sup>1</sup>, Sergio Koifman<sup>1</sup>, Rosalina J. Koifman<sup>3</sup>*

**Abstract:** AIM: To analyze the interaction between SNP Arg72Pro and selected environmental factors in women with benign breast disease(BBD). METHODS: An exploratory cross-sectional study on cohorts of 303 women diagnosed with proliferative BBD from two public hospitals in Rio de Janeiro. Patients were interviewed by three trained nurses to collect environmental's exposure and blood sample were taken afterwards. DNA extraction was performed by the salting-out technique and genotyping was proceeded by PCR-RFLP. The presence of the wild Arg/Arg genotype was indicated by two bands of 169 bp and 127 bp, the the mutant Pro/Pro genotype was observed by a single band of 296 bp and the Arg/Pro genotype was observed by the presence of these three bands. Interaction ORs and respective 95% confidential intervals were estimated using the non-conditional Multiple Logistic Regression. RESULTS: Frequency of Polymorphic allele (Pro) was 40%, while the frequencies of genotypes were 37.4% (Arg/Arg), 45.2 (Arg/Pro) and 17.4% (Pro/Pro). An interaction was observed between Arg/Pro genotype and exposure to solvents [OR = 2.99 (95% CI, 1.35-6.65)], and age at tobacco smoking onset >18 years old [OR=4.16;(95%CI, 0,66-26.14)]. Compared to women Arg/Arg, the chance of proliferative disease was independently higher among women Arg/Pro as [OR=2.19;(95%CI, 1.16-4.16)], while the dominant model was statistically associated to proliferative breast disease [OR=2.03;(95%CI, 1.11-3.69)]. CONCLUSION: Solvent exposures seems to interact with heterozygous genotype of SNP Arg72Pro, while tobacco smoking still needs to be explored. The heterozygous genotype (Arg/Pro) independently increased the chance of proliferative breast disease, as well as the dominant model of SNP Arg72Pro.

### **P03.3070. Prenatal Exposure to Organophosphate Esters and Cognitive and Behavioral Development**

Kate Hoffman

**Abstract:** Background: Limited evidence suggests that organophosphate esters (OPEs) may be neurotoxic or endocrine-disrupting, and may interfere with cognitive and behavioral development in humans. Objective: To estimate the effect of maternal OPE metabolite levels during pregnancy on cognitive and behavioral development in offspring. Methods: Women provided a urine sample during pregnancy that was analyzed for concentrations of OPE metabolites (n=349), including diphenyl phosphate (DPHP), bis(1,3-dichloro-2-propyl phosphate) (BDCIPP), 1-hydroxyl-2-propyl bis(1-chloro-2-propyl) phosphate (BCIPHPP), and isopropyl-phenyl phenyl phosphate (ip-PPP). Approximately 36 months after birth, assessments of cognitive development using the Mullen Scales of Early Learning (MSEL; n=341) and behavioral development using the Behavioral Assessment Scale for Children (BASC; n=332) were obtained. Generalized Linear Models were used to estimate associations between ln-transformed, specific gravity-corrected OPE metabolite concentrations and children's scores on the neurodevelopmental assessments, adjusted for maternal age, maternal race, maternal education, familial poverty, child's age at testing, and child's sex. Results: ip-PPP was inversely associated with scores on the MSEL Cognitive Composite ( $\beta=-4.6$ ; 95% CI: -7.9, -1.3), Expressive Language ( $\beta=-2.5$ ; 95% CI: -4.3, -0.7), and Fine Motor ( $\beta=-3.3$ ; 95% CI: -5.7, -0.9) scales. Other compounds were not associated with MSEL scales. Both DPHP and BDCIPP were significantly positively associated with Attention Problems and Atypicality Scores. BDCIPP was also positively associated with Aggression, Withdrawal, Externalizing, and Behavioral Symptoms Index scores. ip-PPP was inversely associated with scores on Anxiety, Depression, and Internalizing Problems. Conclusions: We identified several associations suggestive of adverse neurodevelopmental effects of prenatal exposure to OPEs that warrant further investigation for neurotoxicity.

**P03.3080. Gene-Environmental Interaction between Cyp1a1, Cyp1b1, and Cyp2b6 Polymorphisms and Vitamin D on Insulin Resistance: A Panel Study of an Elderly Population**

Yun-Chul Hong

*2. Sejong Univeristy, Seoul, Korea (the Republic of).*

**Abstract:** Objective: As evidence on effect of vitamin D deficiency over insulin resistance(IR) or diabetes mellitus is accumulating, investigation for any gene-environmental contribution to disease development should be accompanied. We thus evaluated the influence of certain cytochrome P450 polymorphisms and vitamin D levels on IR. Methods: Glucose, insulin as well as 25-hydroxyvitamin D levels [25(OH)D] levels from serum, and CYP1A1, CYP1B1, CYP2B6 single-nucleotide polymorphisms (SNPs) from lymphocyte DNA were measure in 535 Seoul residents over 60 years old. Homeostasis model assessment for insulin resistance(HOMA-IR) was calculated, and repeated measure analyses were used to determine the statistical association. Results: Relationship between 25(OH)D insulin ( $\beta = -0.84$ ,  $P = 0.02$ ) or HOMA-IR ( $\beta = -0.26$ ,  $P = 0.04$ ) was inversely significant, and influence of CYP1A1 (rs1048943), CYP1B1 (rs162561, rs2551188) and CYP2B6 (rs3745274) SNPs on IR was found across different genotypes. Estimated effect of 25(OH)D levels on IR in the group with higher risky genotype scores of selected SNPs was greater than the group with lower genotype score. Interaction effect between vitamin D levels and genotype variations was also observed ( $P$ -interaction  $<.05$  for both insulin and HOMA-IR). Conclusion: Genetic variations in CYP1A1, CYP1B1 and CYP2B6 and the serum levels of 25(OH)D showed interactive effect on IR.

**P03.3090. Joint-Associations of Metal Exposure Biomarkers and Systolic Blood Pressure in the United States: Findings from the 1999-2004 National Health and Nutrition Examination Survey (NHANES)**

Matthew Gribble

2. Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, NY, United States.

Abstract: Characterizing the joint toxicity of multiple exposures can be challenging due to the large number of potential exposures and limited prior knowledge of how those combined effects may manifest. One approach to modeling exposure combinations is recursive partitioning, but these algorithms traditionally have not been appropriate for data collected via a complex survey design. We used recursive partitioning for modeling survey data (RPMS) which appropriately accounts for the clustering, strata, and unequal probability of selection inherent in complex national survey data to estimate the joint associations between 11 metals biomarkers with systolic blood pressure (SBP) in the National Health and Examination Survey (1999-2004), adjusting for age, sex, race, and smoking status. We found that those with urinary lead (Pb) > 0.99 µg/g creatinine had a mean SBP = 123.17 mmHg, while those with Pb ≤ 0.99 µg/g creatinine had a mean SBP = 117.79 mmHg, conditional on having higher barium (Ba > 1.19 µg/g creatinine) and antimony (Sb > 0.11 µg/g creatinine). Interestingly, Pb was not significantly associated with SBP in traditional survey linear regression using the above threshold ( $\beta_1 = 0.70$ , 95% CI = -0.93, 2.32) or log-transformed Pb ( $\beta_1 = -0.19$ , 95% CI = -1.26, 0.88). We also observed that the joint-associations differed by race and Hispanic origin, although Pb was always involved. The highest predicted SBP was conditional on blood Cd > 0.25 µg/L and blood Pb > 1.75 µg/dL for black Americans (SBP = 128.66 mmHg), on urinary Ba > 1.44 µg/g creatinine and urinary Pb > 1.25 µg/g creatinine among Mexican Americans (SBP = 125.99 mmHg) and on urinary Ba > 1.51 µg/g creatinine, urinary Pb > 0.67 µg/g creatinine, and urinary Sb > 0.16 µg/g creatinine for non-Hispanic white Americans (SBP = 123.60 mmHg). This work demonstrates the utility of survey-consistent recursive partitioning to identify joint-associations in large survey datasets with rich environmental exposure data.

### **P03.3100. Contribution of Glutathione and Metallothionein to Acute Toxicity of Cadmium**

Maki Tokumoto

*Maki Tokumoto<sup>1</sup>, Jinyong Lee<sup>1</sup>, Masahiko Satoh<sup>1</sup>*

*1. School of Pharmacy, Aichi Gakuin University, Nagoya, Aichi, Japan.*

Abstract: Cadmium (Cd) is a harmful heavy metal widely present in the environment. Liver and kidney are the target tissues of acute and chronic Cd exposure, respectively. Glutathione (GSH) and metallothionein (MT)-I/II are known as defensive factors against Cd, but no studies have been conducted to compare them at the same time. In this study, to clarify the contribution of GSH and MT-I/II to acute toxicity of Cd, we examined using GSH-depleted mice and MT-I/II null mice. GSH-depleted mice were prepared by subcutaneously administering L-Buthionine-sulfoximine after 20 h of fasting to 10-week-old female C57BL/6J wild-type mice. GSH-depleted mice, MT-I/II null mice, and wild-type mice were subcutaneously treated with 17.5  $\mu\text{mol}$  Cd/kg. Twenty-four hours later, GOT and GPT activities, and urea nitrogen (BUN) and creatinine (Cre) levels in the serum were measured as an indicator of hepatotoxicity and nephrotoxicity. Cd did not induced hepatotoxicity and nephrotoxicity in wild-type mice. On the other hand, GOT and GPT activities, and BUN and Cre levels in GSH-depleted mice and MT-I/II null mice were significantly increased by Cd. Both hepatotoxicity and nephrotoxicity in GSH-depleted mice treated with Cd were stronger than those in MT-I/II null mice. All of GSH-depleted MT-I/II null mice died by Cd. These results suggested that GSH plays an important role as a biological protective factor against acute toxicity of Cd compared with MT-I/II.

### **P03.3110. The Involvement of Glucose Transporter Gene Expression in Cadmium Renal Toxicity**

Masahiko Satoh

*Masahiko Satoh<sup>1</sup>, Jinyong Lee<sup>1</sup>, Maki Tokumoto<sup>1</sup>*

*1. School of Pharmacy, Aichi Gakuin University, Nagoya, Japan.*

**Abstract:** Cadmium (Cd) is an environmental contaminant known to exert renal toxicity. Proximal tubular cell damage is characterized as Cd-induced renal toxicity. Previous studies revealed that Cd caused the gene expression disruption in proximal tubular cells. However, the transcription factors that regulate the expression of genes associated with Cd renal toxicity are poorly understood. Our previous study demonstrated MEF2A (myocyte enhancer factor 2A) transcription factor that is involved in Cd toxicity in HK-2 human proximal tubular cells, using protein/DNA binding array and RNAi method. In this study, it was investigated which downstream factor of MEF2A is involved in Cd toxicity in HK-2 cells. MEF2A is reported to regulate the gene expression of SLC2A4, which encodes GLUT4 (glucose transporter 4) protein. We found that SLC2A4 expression is regulated by MEF2A in HK-2 cells. Moreover, Cd decreased not only the mRNA level of SLC2A4 but also the protein level of GLUT4 in HK-2 cells. In addition, SLC2A4 knockdown by siRNA conferred the toxicity to HK-2 cells. On the other hand, GLUT2 protein is reported to be expressed abundantly in the mammalian kidney. However, the knockdown of the GLUT2 encoding gene, SLC2A2, did not induce the toxicity in HK-2 cells. Furthermore, MEF2A knockdown did not inhibit the gene expression of SLC2A2 in HK-2 cells. These results suggest that the pathway of Cd renal toxicity through the decrease in activity of MEF2A involves the suppression of SLC2A4 gene expression.

**P03.3120. Urinary Isoflavones Levels in Relation to Thyroid Function in Adults from NHANES 2007-2010**

Patricia Janulewicz

*Patricia A. Janulewicz<sup>1</sup>, Jeffrey M. Carlson<sup>1</sup>, Amelia K. Wesselink<sup>2</sup>, Lauren A. Wise<sup>2</sup>, Elizabeth E. Hatch<sup>2</sup>, Lariah M. Edwards<sup>1</sup>, Junenette L. Peters<sup>1</sup>*

*1. Environmental Health, Boston University, Boston, MA, United States.*

*2. Epidemiology, Boston University, Boston, MA, United States.*

**Abstract:** Background: Isoflavones are phytoestrogens commonly found in plant-based foods and nutritional supplements. Some studies have reported inverse associations between isoflavone intake and selected health outcomes, including cancer, cardiovascular disease, and osteoporosis. However, there is growing concern that isoflavones may affect thyroid status. Experimental studies have shown a relationship between isoflavones and hypothyroidism, but human studies have reported conflicting results. Method: Using cross-sectional data from the National Health and Nutrition Examination Survey (2007-2010), we examined the association between urinary isoflavone concentrations and serum measures of thyroid function in adults free of thyroid disease. Specifically, we conducted multivariable analyses relating the concentrations of each urinary isoflavone (genistein, daidzein) and their metabolites (equol, O-desmethylangolensin [O-DMA]) to serum concentrations of thyroid stimulating hormone [TSH], free triiodothyronine [T3], total T3, free thyroxine [T4], total T4, thyroperoxidase [TPO] antibodies, adjusting for sociodemographics, creatinine, iodine and thiocyanate. Results: We observed positive associations between daidzein and O-DMA and free T4, and an inverse association between equol and total T4. Daidzein and O-DMA associations were stronger among women: A 10-fold increase in daidzein was related to a 3.2% (95% CI: 1.9%, 4.5%) increase in free T4, and a 10-fold increase in O-DMA was related to a 2.0% (95% CI: 1.1%, 2.9%) increase in free T4. The equol association was stronger among men: A 10-fold increase in equol was related to a 1.8% decrease (95% CI: -3.4%, -0.13%) in total T4. Conclusion: In the present study, isoflavone intake was associated with selected thyroid hormones in a sex-dependent fashion.

### **P03.3130. Urinary Lignan Levels and Thyroid Function in Adults from NHANES 2007-2010**

Jeffrey Carlson

*2. Department of Epidemiology, Boston University School of Public Health, Boston, MA, United States.*

**Abstract:** Background: Enterodiol and enterolactone are lignans, a group of phytoestrogens produced by bacteria in the colon that act on plant precursors. Flaxseed is the largest dietary source of lignans, but are also found in other seeds, grains, fruits, and vegetables. Health effects research on enterodiol and enterolactone is limited. However, some studies find associations between high dietary lignan exposure and reduced risk of thyroid and breast cancer and cardiovascular disease. Method: We performed a cross-sectional analysis examining the relation between urinary lignan concentrations and serum of thyroid levels in adults free of thyroid disease in the National Health and Nutrition Examination Survey (2007-2010). Specifically, we conducted multivariable analyses relating the concentrations of each urinary lignan (enterodiol, enterolactone) to serum concentrations of thyroid stimulating hormone [TSH], free triiodothyronine [T3], total T3, free thyroxine [T4], total T4, thyroperoxidase [TPO] antibodies, adjusting for sociodemographics, creatinine, iodine and thiocyanate. Results: In women, enterodiol and enterolactone were inversely associated with total T4. A 10-fold increase in enterodiol was associated with a 1.8% decrease (95% CI: -2.8%, -0.89%) in total T4, and a 10-fold increase in enterolactone was associated with a 1.6% decrease (95% CI: -2.5%, -0.68%) in total T4. Among men, a 10-fold increase in enterolactone was associated with a 1.0% increase (95% CI: -2.32%, 0.23%) in total T4 and a 10-fold increase in enterodiol was associated with a 2.1% decrease (95% CI: -3.4%, -0.82%) in total T4. In addition, among women, there was an inverse association between enterolactone and free T3, where a 10-fold increase in enterolactone was associated with a 1.6% decrease (95% CI: -2.5%, -0.68%) in free T3. Conclusion: In the present study, urinary lignan concentrations were associated with serum concentrations of selected thyroid hormones in a sex-dependent fashion.

### **P03.3140. Association between Antibiotics in Urines and Adult Obesity in Shanghai**

Hexing Wang

*Hexing Wang<sup>1</sup>, Xin Yu<sup>1</sup>, Qingwu Jiang<sup>1</sup>, Zhijun Zhou<sup>1</sup>*

*1. School of Public Health/ Key Laboratory of Public Health Safety of Ministry of Education, Fudan University, Shanghai, China.*

**Abstract:** Background: Exposure to antibiotics was found to be one possible risk factor of child obesity, but the information on adults is limited. Objective: To investigate the association between antibiotics in urines and adult obesity in Shanghai. Methods: 530 adults aged 21-75 years from two towns located in the suburb of Shanghai were studied in 2017. Their spot urines and demographic data were collected and the anthropometric measurements were performed. 18 common used antibiotics from five categories (4 fluoroquinolones, 4 tetracyclines, 3 phenicols, 3 macrolides, and 4 sulfonamides) were determined in urines by the isotope dilution-based UPLC-Q/TOF MS. These subjects were classified into 3 groups, namely normal weight, overweight, and obesity, based on the body mass index-based cutoff points recommended by the guidelines on prevention and control of overweight and obesity in Chinese adults. The multinomial logistic regression model was used to explore the association of antibiotic concentration sum by category with overweight and obesity. Results: The overall detection frequencies of five antibiotic categories ranged from 1.9% to 28.7%. Compared to the subjects in the tertile 1 of concentration sum of fluoroquinolones, the adjusted odds ratios (ORs) of subjects in tertile 3 were 1.56 (95% confidence interval: 0.90, 2.71; p-Value: 0.116) for overweight and 0.97 (0.42, 2.26; 0.948) for obesity. Similarly, for tetracyclines, the ORs were 6.06 (1.63, 22.52; 0.007) for overweight and 2.88 (0.46, 18.08; 0.259) for obesity and for phenicols, the ORs were 4.50 (1.43, 14.15; 0.010) for overweight and 8.16 (2.20, 30.23; 0.002) for obesity. Sex-specific associations with overweight or obesity were observed for some antibiotics. Conclusion: Some antibiotics in urines were found to be associated with an increased risk of adult overweight or obesity. In view of the cross-sectional design of our study, longitudinal studies are warranted to further test these findings.

**P03.3150. Environmental Risk Factors for Benign Prostate Hyperplasia: A Case-Control Study in Hong Kong Chinese**

Lap Ah Tse

*2. Department of Oncology, Prince of Wales Hospital, Shatin, N.T., Hong Kong.*

*3. SH Ho Urology Centre, Department of Surgery, The Chinese University of Hong Kong, Shatin, N.T., Hong Kong.*

**Abstract:** Objective: To document associations between environmental risk factors and benign prostate hyperplasia (BPH) among Hong Kong men using a case-control study. Methods: We recruited 431 newly diagnosed prostate cancer cases and 402 age-matched controls from Prince of Wales Hospital in Hong Kong. We further consecutively recruited 855 BPH cases from the urological outpatients who were confirmed by biopsy to be non-malignancy. We adopted a standardized questionnaire to obtain each participant's information on shift work, diets, habits of using food and water containers, household detergents and pesticide usage, etc. We applied a new assessment tool of environmental bisphenol A exposure (BPA) developed in our previous publication on BPA and prostate cancer to each BPH case to calculate a novel cumulative BPA exposure index (CBPAI). Compared with the distribution of exposures among controls, we estimated odds ratio (OR) and 95% confidence interval (95% CI) for BPH using multiple logistic regression analysis. Results: Shift work was more common among BPH cases (12.9%) than the controls (7.5%), showing an adjusted OR of 1.90 (95%CI: 1.23-2.94). Weekly consumption of deep fried food and pickle vegetables was positively associated BPH with OR of 2.25 (95%CI: 1.49-3.38) and 1.85 (95%CI: 1.12-3.05), respectively. Habitually drinking green tea had benefits (OR=0.61, 95%CI: 0.41-0.92) but habitual coffee consumption showed harmful (OR=1.59, 95%CI: 1.17-2.15). A significant positive gradient between exposure to CBPAI and risk of BPH was observed. Conclusions: This study identified weekly consumption of deep fried/persevered foods, habitual coffee drinking and frequent use food/water containers are risk factors of BPH, but habitual green tea drinking is protective. This study is the first to provide an integrated picture on the etiology of BPH. [Acknowledgement: Health and Medical Research Fund (HMRF), Project No.: 11121091; correspondence: shelly@cuhk.edu.hk]

### P03. Biomarkers of Exposure and Effects 3

#### **P03.3160. Biomonitoring of Exposure to Great Lakes Contaminants in New York State Burmese Refugees: Recruitment Strategy, Descriptive Characteristics, and Fish Consumption Patterns**

**Abstract:** The Buffalo River in Buffalo, NY is a highly industrialized river and an ongoing Great Lakes Area of Concern. The New York State Department of Health (NYSDOH) conducted a biomonitoring study to assess exposure to persistent contaminants among adult Burmese refugees residing in Buffalo who may have increased risk of exposure due to frequent consumption of locally caught fish. The chemicals measured include metals, polychlorinated biphenyls, persistent pesticides, per- and polyfluoroalkyl substances, and polybrominated diphenyl ethers. An advisory committee provided invaluable assistance throughout program planning, implementation, and outreach. The committee included local refugee resettlement agencies, academia, and state and local health departments. In 2013, 206 participants were recruited using respondent driven sampling, a method suitable for reaching "hidden" populations with no known sampling frame. Survey data collected included residential history, education and employment history, lifestyle factors, and information on catch location and species-specific consumption of locally caught fish. Culturally oriented information was also collected, including country of birth, history of living in refugee camps, preparation and consumption of fish paste, use of Thanakar (a cosmetic), and betel nut (a mild stimulant). The Burmese participants reported eating a substantial amount of locally caught fish with a median of 88 meals in the previous year. A majority of participants (80%) reported eating fish paste (either store-bought or homemade) 52 times per year or more. Over half of the participants were not aware of the health advice on eating fish caught in local waters. The NYSDOH used the biomonitoring data to develop and provide educational materials related to exposure reduction for this population. Information was provided on choosing the right fish species for consumption, recommended local waters to fish from, and the best methods of fish preparation.

### **P03.3170. Use of High-Resolution Metabolomics to Identify Potential Metabolic Pathways Associated with Traffic-Related Air Pollutants**

**Abstract:** Background. High-resolution metabolomics (HRM) has emerged as a promising analytical platform for measuring environmental exposures and corresponding biological response. Questions remain, however, whether HRM can be a sensitive tool for biomarker discovery, especially over short exposure durations. Methods. We conducted HRM to identify potential metabolic pathways and internal biomarkers associated with primary traffic emissions within the Dorm Room Inhalation to Vehicle Emission (DRIVE) study. We measured a suite of air pollutants at multiple ambient and indoor sites along a major highway artery over 12 weeks. In parallel, 54 students living in dormitories either near (20 m) or far (1.4 km) from the highway underwent personal sampling and contributed plasma and saliva. We conducted untargeted HRM on all samples, followed by a Metabolome-Wide Association Study (MWAS), pathway analyses and tandem mass spectrometry (MS/MS). Results. In total, over 20K metabolite features were reliably extracted from plasma, and over 29K from saliva. Over 1300 features were significantly associated with at least one or more traffic pollutant (e.g., black carbon, carbon monoxide, nitrogen oxides ( $p < 0.05$ ), when controlling for covariates and false discovery rate. Pathway analysis indicated elicitation of several inflammatory pathways, including leukotriene metabolism and vitamin E metabolism. We validated 10 metabolites associated with traffic pollutants using MS/MS, including hypoxanthine, g-linolenic acid, L-Histidine, L-Proline, and L-Arginine. Conclusions. We successfully identified and verified several pathways and metabolites using HRM, most consisting of endogenous metabolic signals related to oxidative stress, inflammatory response and nucleic acid damage and repair. These findings offer promising initial evidence of the potential of this analytic platform as a tool for biomarker discovery to ubiquitous environmental stressors.

### **P03.3180. Blood Lead Concentration in Childhood and Age of Menarche in a Prospective Study of U.S. Girls**

Abstract: Lead may alter growth and development, but prospective studies on menarche are lacking. Among girls enrolled at 6-8 years of age in the Breast Cancer and Environment Research Program cohort during 2004-2007 and followed up to 11 years, lead in blood (PbB) was measured in a single sample, primarily before menarche but up to 7 years after. Median PbB was 0.95 ug/dL (IQR 0.69-1.3) and age of menarche 12.2 years (IQR 11.2-13; n=809). Associations of ln(PbB) with menarcheal age were estimated using Cox proportional hazards models adjusted for age and height at PbB sample collection and race/ethnicity. Associations were null in unadjusted models. Adjusted associations were also null among all girls or those whose PbB sample was obtained 2-9 years before menarche (n=654, aHR 1.02 95%CI 0.86 - 1.22). If PbB was measured within 1 year of menarche or after, the association was inverse (n=155, aHR 0.64, CI 0.43-0.96). The latter finding closely resembles those of prior cross-sectional studies and may arise because PbB concentrations decline during childhood when PbB is diluted by body size during maximal growth. The group of 155 girls with PbB obtained near or after menarche differed significantly from the 654 followed prospectively, with older median age at sampling of 11 vs. 8 years old, lower PbB: 0.76 vs. 0.99 ug/dL, taller height: 60 vs. 50 in; and earlier menarcheal age: 11.1 vs. 12.4 years, respectively. Therefore, cross-sectional studies reporting associations of PbB with delayed menarche may not have adequately adjusted for rapid growth or measured PbB in an appropriate susceptibility window. During childhood, intercorrelations among PbB, height, age, and menarche can seriously confound associations. In our longitudinal analysis with pre-pubertal PbB measures there was no association with age of menarche. These findings and conclusions have not been disseminated by the Centers for Disease Control and Prevention and do not represent any agency determination or policy.

**P03.3190. Global Metabolic Profiling of Dried Blood Spot Samples for Personal Air Pollution Exposure in Population Studies**

**Abstract:** Background: Exposure assessment and clinical diagnostics are major barriers to assessing the chronic disease impacts of household air pollution, an exposure impacting over half the world's population. The potential of global metabolic profiling of dried blood spots (DBS) for investigating air pollution exposure is of interest to epidemiology and exposure studies due to its relatively simple and low-cost collection method. However, its application and adoption for household air pollution exposure has not been evaluated. Methods: We aimed to assess the metabolic changes associated with exposure to fine particulate matter (PM<sub>2.5</sub>) in a cross sectional study of 33 women in rural China using traditional biomass stoves. We measured women's 48-hour personal exposure to PM<sub>2.5</sub>, blood pressure (BP) and demographic/anthropometric variables in summer 2016 and winter 2016/17, and acquired metabolic profiling of DBS using ultra-performance liquid chromatography-mass spectrometry (UPLC-MS). Results: The mean systolic BP was 111.6 (95% CI 105.8, 117.4) mmHg in summer and 119.6 (95% CI 115.2, 125.3) mmHg in winter; and their corresponding median personal exposure of PM<sub>2.5</sub> was 38.6 (95% CI 30.6, 45.7) mg/m<sup>3</sup> in summer and 145.8 (95% CI 141.2, 167.5) mg/m<sup>3</sup> in winter. Orthogonal partial least square-discriminant analysis (OPLS-DA) on UPLC-MS data comparing women with below median exposure to PM<sub>2.5</sub> in summer with those with above median exposure in winter showed distinct differences in their DBS profiles. The discriminatory metabolites contributed to this separation including hydroxanthine (requires for nucleic acid synthesis and energy metabolism) and sphingolipids (plays a role in protection of cell from harmful external factors). Conclusions: Our UPLC-MS method on DBS for global metabolic profiling in population-based studies of household air pollution may be used to gain mechanistic insights into the health impacts of seasonal PM<sub>2.5</sub> exposure.

**P03.3200. Biomonitoring of Exposure to Great Lakes Contaminants in New York State Burmese Refugees: Assessing Exposure to Per- and Polyfluoroalkyl Substances (PFAS) and Its Association with Local Fish Consumption**

Ming Liu

*Ming Liu<sup>1</sup>, Sanghamitra S. Savadatti<sup>1</sup>, Wan-Hsiang Hsu<sup>1</sup>, Kurunthachalam Kannan<sup>1</sup>, Wei Wang<sup>1</sup>, Elizabeth Irvin-Barnwell<sup>2</sup>, Zheng Li<sup>2</sup>, Syni-An Hwang<sup>1</sup>*

*2. Agency for Toxic Substances and Disease Registry, Atlanta, GA, United States.*

**Abstract:** Background: Fish consumption is a potential source of PFAS exposure, but few studies have looked at the associations between fish consumption and PFAS exposure. Burmese refugees and immigrants in Buffalo, NY consume a substantial amount of fish caught from the Great Lakes and surrounding waters, raising their risk of exposure to contaminants including PFAS. The aims of this study were to: (i) present the PFAS exposure profile of the Burmese refugees, and (ii) examine the associations between PFAS levels and local fish consumption. Methods: Burmese participants (n=199) provided blood samples and completed a detailed questionnaire. We measured 12 PFAS compounds in serum. Multiple linear regression was used to assess associations between PFAS concentrations and self-reported consumption of fish from the Great Lakes waters. Results: Local fish consumption was high among study participants (median: 3 meals/week in summer, 1 meal/week in winter). Nine PFAS were detected in at least 65% of participants. PFOS had the highest median concentration (35.6 µg/L), 6 times that of the U.S. general population. We selected the 5 most abundant PFAS (PFOS, PFHxS, PFOA, PFNA, and PFDA) with 100% detection rate for further regression analysis. Consumption of fish/shellfish within the past 3 days was associated with elevated PFOS and PFNA. There was evidence of potential effect modification by ethnicity (Karen and Other). Higher consumption of Great Lakes fish in summer and consuming fish/shellfish within the past 3 days were associated with PFOS and PFDA among the Burmese of 'Other' ethnicity, but not among participants of Karen ethnicity. Conclusions: Burmese refugees and immigrants in western New York had elevated blood PFAS concentrations (especially PFOS) and some PFAS were associated with Great Lakes fish consumption. Besides local fish consumption, there may be other PFAS exposure routes related to ethnicity in this population.

### **P03.3210. Maternal Diet during Pregnancy and Blood Cadmium Concentrations in a Cohort of British Women**

Katarzyna Kordas

Abstract: Food is the main source of cadmium (Cd) exposure in non-smoking populations. We examined maternal diet in pregnancy as predictor of blood Cd (BCd) in women from the Avon Longitudinal Study of Parents and Children (ALSPAC). Women reported on frequency of consumption of 43 foods and drinks, later combined into 10 groups: meats; fish; pulses; nuts; soybean products; root vegetables; leafy greens and green vegetables; breads and cereals; cakes and biscuits; pastas/rice. PCA was used to derive five dietary patterns: 'health conscious' (high in salad, fruit, rice, pasta, oat and bran-based breakfast cereals, fish, pulses, fruit juices and non-white bread); 'traditional' (high in vegetables and red meat and poultry); 'processed' (high in high-fat processed foods, such as meat pies, sausages and burgers, fried foods, pizza, chips and baked beans); 'confectionery' (high in foods with high sugar content: chocolate, sweets, biscuits, cakes and other puddings) and 'vegetarian' (high in meat substitutes, pulses, nuts and herbal teas; low in red meat and poultry). BCd was measured via ICP-MS in whole blood taken in early pregnancy (median 11 wks). Samples median in relation to diet. Sensitivity analysis excluded smokers. Closer adherence to the 'health conscious' pattern (covariate-adjusted OR [95% CI]: 0.56 [0.39-0.81]), frequent consumption of leafy greens and green vegetables (0.72 [0.56-0.92]) or meat (0.66 [0.46-0.95]) were associated with lower likelihood of elevated BCd compared with reference groups. Sensitivity analysis mirrored main findings. Adherence to a healthy diet in pregnancy is related to lower Cd levels.

**P03.3220. Association between Blood Heavy Metal Concentrations and Metabolic Syndrome Related Biomarkers among Reproductive Age Women of Korea**

Abstract: Metals have been reported for possible associations with metabolic symptoms, but existing information remains contradictory. In the present study, the association between metal exposure and the metabolic symptom related biomarkers among reproductive age women was investigated. The participating women (n=516, aged 20s to 40s) were recruited from major cities throughout Korea between 2015 and 2016, and measured for lead (Pb), cadmium (Cd), and mercury (Hg) in blood samples. Metabolic syndrome (MetS) related biomarkers such as adiponectin, leptin, glucose, insulin, high density lipoprotein (HDL)-cholesterol, triglycerides (TG), and total cholesterol (TC) were also analyzed in serum. The participants were instructed to fast at least 9 hours before the blood sampling. Logistic regression was used to assess the association between blood heavy metal concentrations and the MetS related biomarkers. Blood Pb and Hg concentrations in quartiles were positively associated with homeostasis model assessment-insulin resistance (HOMA-IR), which was defined as exceeding the 75 percentile of HOMA-IR, after adjusting for age, body mass index (BMI), alcohol consumption status, and smoking. These observations suggest that exposure to Pb and Hg may be associated with MetS among reproductive age women. Further studies for confirming this association in other populations are warranted.

**P03.3230. Temporal Variation of Total Mercury Levels in the Hair of Pregnant Women from the MIREC (Maternal-Infant Research on Environmental Chemicals) Study**

Cheryl Khoury

*Anna Lukina<sup>1</sup>, Cheryl Khoury<sup>1</sup>, John Than<sup>1</sup>, Mireille Guay<sup>1</sup>, Jean-Francois Paradis<sup>1</sup>, Mandy Fisher<sup>1</sup>, Tye Arbuckle<sup>1</sup>*

Abstract: Prenatal exposure to mercury (T-Hg) comes from both natural and anthropogenic sources. T-Hg can cross the blood-placental barrier, transfer from mother to fetus, and may be associated with future neurological (memory loss, personality changes, deafness and vision loss, attenuation of IQ) and physiological (delays in walking and talking, tremors and convulsions) dysfunctions. Hair is an optimal and non-invasive indicator of chronic T-Hg exposure. On average, scalp hair grows about 1.1 cm per month. As part of the Maternal-Infant Research on Environmental Chemicals (MIREC) Study, hair samples of 350 women were collected within weeks after giving birth, to determine temporal variation of T-Hg from conception to delivery, and to compare these levels to levels measured in other matrices (maternal and umbilical cord blood, breast milk, and infant's meconium). One centimeter sequential hair samples were collected, starting at the scalp and up to 12 cm. Overall, T-Hg levels decreased over the course of pregnancy. Mercury levels in hair positively correlated with levels in blood, but not with levels in meconium or breast milk. A higher mean mercury level was found in cord blood, meaning that it was able to pass the placental barrier, but did not reach the fetus, since the majority of meconium samples had mercury below the detection limit. This study generates knowledge on the monthly variation of mercury in a pan-Canadian pregnancy cohort and provides a unique opportunity to compare mercury levels from multiple matrices from pregnant women and their infants.

### **P03.3240. Perfluorinated Alkyl Substances and Association with Response Biomarkers among NHANES 2005-2010 Subjects**

Dina Schreinemachers

*Dina M. Schreinemachers<sup>1</sup>, Andrew J. Ghio<sup>1</sup>*

*1. EPHD/NHEERL/ORD, U.S. EPA, Durham, NC, NC, United States.*

Abstract: Presence of perfluorinated alkyl substances (PFAS) in the environment is widespread. These stable chemicals have half-lives in the human body of several years. Their presence has been linked to several diseases. This study explores the link between PFAS exposure and disease, by use of biomarkers. Male and nonpregnant female subjects were selected if they had been tested for PFAS, were between ages 20 and 49, and had not experienced any chronic diseases. From the 12 available PFAS, five were selected based on their high percentage ( $\geq 75\%$ ) above the limit of detection: perfluorooctanoic acid (PFOA), perfluorooctane sulfonic acid (PFOS), perfluorohexanesulfonic acid (PFHS), perfluorodecanoic acid (PFDE), perfluorononanoic acid (PFNA). By standardizing and summing up these chemicals, an overall exposure measure (PFSUM) was created to study associations with early and late response biomarkers. Ferritin, serum creatinine, platelet count, and serum uric acid were selected for the initial association with PFSUM. These biomarkers are known to be associated with the metabolic syndrome and associated diseases. Significant Spearman correlations with PFSUM were observed for the following biomarkers for males: platelets (0.110,  $p < 0.01$ ), serum creatinine (0.205,  $p < 0.0001$ ), serum uric acid (0.112,  $p < 0.01$ ), and for females (ferritin 0.233,  $p < 0.0001$ , serum creatinine 0.201,  $p < 0.0001$ ). Initial observations have shown that these four biomarkers are correlated with biomarkers known to be associated with system damage, such as inflammation, liver function, glucose metabolism, lipid metabolism, and blood pressure. The results indicate that PFAS may be linked to disease by a series of adverse health outcomes. This abstract does not necessarily reflect EPA policy.

**P03.3250. The Association of Urinary Phosphorous-Containing Flame Retardant Metabolites and Self-Reported Personal Care and Household Product Use among Women from the Puerto Rico Testsite for Exploring Contamination Threats (PROTECT) Study**

Mary Ingle

*Mary E. Ingle<sup>1</sup>, Deborah Watkins<sup>1</sup>, Zaira Rosario<sup>4</sup>, Carmen Vélez-Vega<sup>4</sup>, Jose Cordero<sup>3</sup>, Akram Alshawabkeh<sup>2</sup>, John Meeker<sup>1</sup>*

*1. Environmental Health Sciences, University of Michigan, Ann Arbor, NC, United States.*

*2. Northeastern, Boston, MA, United States.*

*3. University of Georgia, Athens, GA, United States.*

*4. University of Puerto Rico, San Juan, Puerto Rico.*

**Abstract:** Background Phosphorous-containing flame retardants (PFRs) are widely detected among pregnant women in the U.S. PFRs have been associated with endocrine disruption and adverse reproductive health outcomes. Although mainly used as a flame retardant, increased PFR exposure has been associated with personal care product (PCP) use. Methods Pregnant women 18-40 yrs. were recruited from two hospitals and five prenatal clinics in Northern Puerto Rico (n=148). Metabolites bis-2chloroethyl phosphate (BCEtP), bis-(1-chloro-2propyl) phosphate, bis-(1-chloro-2propyl) phosphate, bis(1,3-dichloro-2-propyl) phosphate (BDCIPP), di-n-butyl phosphate (DBNP), di-benzyl phosphate (DBzP), di-cresyl phosphate (DCP) and diphenyl phosphate (DPHP) were measured in urine three times during pregnancy. Participants completed a 48-hour recall questionnaire of PCP and household product (HP) use (visits 1&3). Associations among products and metabolites (n=296) were assessed using linear mixed models, adjusted for specific gravity, age, BMI, income and season. Results BCEtP, BCPP, BDCPP and DPHP were highly detected (79% $\geq$ LOD), yet correlations among metabolites ( $0.16 \leq r \leq 0.35$ ) and within women ( $0.03 \leq r \leq 0.34$ ) were weak-to-moderate. Correlations among visits were moderate ( $0.20 \leq r \leq 0.43$ ). Suntan lotion use was associated with a 110% increase in BDCPP levels while DPHP increased with reported perfume (51%), nail polish (49%) and cosmetic (45%) use ( $p < 0.05$ ). BCPP levels increased 46% with pesticide use in home, yet DPHP decreased 27% with use of vinyl shower curtain ( $p < 0.05$ ). Furniture polish use was associated with an increase in BCEtP (62%) and BCPP (70%). Conclusion PFRs among pregnant women were highly detected, yet concentrations were weakly correlated with high temporal variability between visits 1&3. Associations with PCP and HP suggests PFRs are possibly being used as plasticizers, specifically in perfume, nail polish and cosmetics. Further investigation into these products is warranted.

### **P03.3270. Advancements in Laser-Ablation ICP-MS for Hair as a Biomarker of Past Exposures**

Boris Reiss

*Boris Reiss<sup>1</sup>, Chelsi White<sup>1</sup>, Mike Paulsen<sup>2</sup>, Christopher D. Simpson<sup>2</sup>, Igor Burstyn<sup>3</sup>*

*2. Environmental and Occupational Health Sciences, University of Washington, Seattle, WA, United States.*

*3. Environmental and Occupational Health, Drexel University, Philadelphia, PA, United States.*

Abstract: Group-based (bulk) hair analysis suggests that hair is a suitable biomarker of past exposure of metals such as lead (Pb), mercury (Hg), and manganese (Mn). However, there is potential to conduct individual-based assessments of exposure to metals using individual hair strands. Such time-resolved exposure analysis involves applying recent developments in laser ablation with inductively coupled plasma spectrometry (LA-ICPMS). Individual hair strands are ablated along the shaft and the aerolized material is analyzed with ICP-MS. The resulting spatial profile along the length of hair strand is expected to present metal exposures over time. Until now, outside hair contamination and calibration issues have limited usability of individual hair strands. Physical properties of individual hair strands cause particulate material to attach to the outside of a strand. Novel washing procedures were developed to remove external hair contamination. Although more than 80 different procedures have been tested over the past decades, their effectiveness is still difficult to assess. In addition, it is challenging to calibrate hair strand analysis against standards, because standard hair strands with known concentrations of metals are not available. We used a novel approach to mounting hair strands and analyzing individual samples in a pilot experiment with hair strands from an Asian woman. Preliminary data suggests that outside particulate contamination can be measured separately from material deposited inside a hair strand. Deposition density of several metals inside a hair strand were determined. In addition, it may be possible to eliminate the need for matrix calibration standards such as standard hair strands. Updates on the development of apprentice welders' hair analysis with LA-ICPMS progress will be added to the presentation.

**P03.3280. Trisaminohexyl Isocyanurate (TAHI) Levels in Plasma and Urine in Workers Exposed to 1,6-Hexamethylene Diisocyanate (HDI) Monomer and HDI Isocyanurate**

Leena Nylander-French

*Zachary Robbins<sup>1</sup>, Wanda Bodnar<sup>1</sup>, Zhenfa Zhang<sup>1</sup>, Avram Gold<sup>1</sup>, Leena A. Nylander-French<sup>1</sup>*

*1. Department of Environmental Sciences and Engineering, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States.*

Abstract: Identification and quantification of trisaminohexyl isocyanurate (TAHI) as a biomarker of 1,6-hexamethylene diisocyanate (HDI) isocyanurate exposure is a critical step for evaluating the contributions of work environment and personal protective equipment practices in limiting isocyanurate exposure. Polymeric HDI isocyanurate is the predominant inhalation and skin exposure in the automotive repair industry, yet, biological monitoring has been limited to metabolites of HDI monomer exposure. We analyzed TAHI and hexamethylene diamine (HDA), a biomarker for HDI monomer exposure, in the plasma and urine of automotive spray-painters. Despite the large number of samples with HDA, daily total urinary HDA and plasma HDA were weakly associated with inhalation exposures to HDI monomer (Urine:  $r = 0.121$ ,  $p = 0.1980$ ; Plasma:  $r = 0.120$ ,  $p = 0.2146$ ) or HDI isocyanurate (Urine:  $r = 0.011$ ,  $p = 0.9112$ ; Plasma:  $r = 0.065$ ,  $p = 0.5015$ ). By comparison, correlations for TAHI were strong with both HDI monomer (Urine:  $r = 0.329$ ,  $p = 0.0003$ ; Plasma:  $r = 0.262$ ,  $p = 0.0062$ ) and HDI isocyanurate inhalation exposures (Urine:  $r = 0.364$ ,  $p = <0.0001$ ; Plasma:  $r = 0.335$ ,  $p = 0.0004$ ). HDA and TAHI levels in urine and plasma had equally strong correlations with HDI monomer and HDI isocyanurate skin exposures. However, due to the collinearity of HDI monomer ( $r = 0.475$ ,  $p = <0.0001$ ) and HDI isocyanurate ( $r = 0.377$ ,  $p = <0.0001$ ) inhalation and skin exposures, the contributions of exposure pathways to biological levels is unknown. Workplace factors such as paint-booth type, coverall and glove use, and respirator type may be equally or more important factors for variation in TAHI levels. Using linear mixed modeling in SAS, we are currently investigating the contributions of exposure pathways and workplace factors on HDA and TAHI levels in plasma and urine in this occupationally exposed worker cohort.

**P03.3290. From Zero to One-Hundred in 15 Years: Urine Samples from the German Environmental Specimen Bank Reveal Omnipresent and Further Increasing Exposures to the Novel Plasticizer Substitute Hexamoll DINCH**

Holger Koch

*Holger M. Koch<sup>1</sup>, Monika Kasper-Sonnenberg<sup>1</sup>, Till Weber<sup>2</sup>, Petra Apel<sup>2</sup>, Claudia Pölmke<sup>1</sup>, Thomas Brüning<sup>1</sup>, Marike Kolossa-Gehring<sup>2</sup>*

*1. Institute for Prevention and Occupational Medicine of the German Social Accident Insurance - Institute of the Ruhr-Universität Bochum (IPA), Bochum, Germany.*

*2. German Environment Agency (UBA), Berlin, Germany.*

Abstract: Hexamoll® DINCH® was introduced in the year 2002 as a substitute for high molecular weight ortho-phthalate plasticizers, which are under scrutiny for their endocrine disrupting effects. In Western Europe, DINCH production rose from 9.000 t in 2002, to 155.000 t in 2014, to a predicted 220.000 t in 2019. In the meantime, human biomonitoring studies have reported on DINCH exposures in several European countries, in the US and in Australia. For Germany, we already reported the rapid increase in detections and levels of DINCH metabolites in 24h urine samples from the Environmental Specimen Bank (ESB) from 1999 to 2012. Here, we report the results of the ESB measurements from the sampling years 2010, 2011, 2013, 2015 and 2017 (a total of 300 24h-urine samples; 60 per year, 30 male and 30 female volunteers, aged 20-29). All samples were blinded and randomized before analysis. Three urinary DINCH metabolites, the side-chain oxidized monoesters OH-MINCH, oxo-MINCH and cx-MINCH, were determined by online SPE LC-MS/MS with isotope dilution quantification. The limit of quantification for all three metabolites was 0.05 µg/L. We first detected the major metabolite OH-MINCH in samples from 2006 (6.7%) with detection rates steadily increasing thereafter (43% in 2009, 80% in 2010, 98% in 2011, 98% in 2012, and 100% in the years 2013, 2015 and 2017). The median concentration for OH-MINCH increased from 0.15 µg/L in 2010 to 0.70 µg/L in 2017. Detection rates and concentrations for the other DINCH metabolites were lower, as expected from human metabolism studies, but strongly correlated among each other. Overall, urinary DINCH metabolite concentrations were well below the health based guidance value (HBM-I) of 4500 µg/L (sum of OH-MINCH and cx-MINCH), and calculated intakes were well below the tolerable daily intake of 1 mg/kg bw\*d. The continuous increase of DINCH exposure calls for a continued exposure monitoring preferably in subpopulations with higher exposure (e.g. children).

### **P03.3300. Accessing Biobanks to Obtain Human Biomonitoring Data**

Kristin Macey

*Dr. Innocent F. Jayawardene<sup>1</sup>, Kristin Macey<sup>1</sup>, Jean-Francois Paradis<sup>2</sup>, Stephane Belisle<sup>2</sup>, Devika Poddalgoda<sup>1</sup>, Sabit Cakmak<sup>3</sup>, Marie-Pier Lafontaine<sup>2</sup>, Noreen Lalji<sup>2</sup>, Robert Dales<sup>3</sup>*

- 3. Health Canada, Environmental Health Science and Research Bureau, Ottawa, ON, Canada.*

**Abstract:** Background: The use of human biomonitoring data allows direct and more precise assessment of the distribution of exposure in a given population. In Canada, biomonitoring data in the general population has been continuously measured since 2007, by the Canadian Health Measures Survey (CHMS). Integrated within the CHMS, the biobank is a nationally representative cohort to facilitate novel health research. Objective: Some of the Chemical Management Plan's priority substances; Al, Bi, Ce, Cr, Ge, La, Li, Nd, Pr, Ti, Te and Y were not included in the CHMS. After obtaining approval from relevant authorities, approx. 6000 whole blood samples from the CHMS biobank were accessed to determine metal concentrations by Inductively Coupled Plasma Spectrometry. Method: Resultant concentrations were expected to be at ppt or ppb levels. The main challenges were: possible leaching of metals from storage and associated materials, non-homogeneity of blood samples, transportation of samples and analytical issues related to testing a large batch of samples in the absence of data for comparison. Leaching was addressed by sequential testing of de-ionized water and blood, mimicking the procedure from the withdrawal of the blood samples, storage and analysis. Non-homogeneity of the samples and possible contamination during analysis were addressed by reproducibility studies. Throughout the project (1.5 years), accuracy, recovery, reproducibility, and contamination were assessed using Certified Blood Reference Materials, a control spiked blood sample, and Method Blanks along with each analytical batch. Results: Recoveries were in an acceptable range of 70-130%; the majority between 80-120%, with an inter assay CV% ranging from 3-11%. Leach testing showed no contamination from the storage or associated materials used for Bi, Ce, Cr, Ge, La, Li, Nd, Pr, Te, except for Y, which had minor contamination close to the detection limit from materials associated with blood withdrawal.

**P03.3310. Increasing the Regulatory Impact of Chemical Safety Research by Following a Standard Procedure: A Human Biomonitoring Physiologically Based Kinetic (PBK) Model Case Study**

Maryam Zare Jeddi

**Abstract:** While progress in chemical safety research in recent years has been impressive, especially in the area of in-vitro and 3R approaches, an obvious gap between scientific ambition on the one hand and awareness of regulatory requirements on the other prevents a more widespread application of latest science findings in current regulatory programs: The resulting delay with which new research is acknowledged, and ultimately accepted by regulators is costly in terms of money, accuracy and ethics. We argue that by following a standard procedure (checklist, vademecum or similar) during conception, execution and publication of research results, scientists can make their output regulatory-aware from the onset, and thereby simplify the uptake in affected legislations. After having reviewed current regulatory programs and interviewed relevant stakeholders within them, we developed a checklist of steps researchers can follow in order make their output more relevant for regulators. The checklist consists of a general part, applicable to all categories of chemical risk assessment research and legislations, while a more sector-specific part deals with the individual specificities of the research type at hand. In a proof of concept case study we partnered with a project that developed a human biomonitoring mixture PBK model to calculate external exposure from biological samples. We accompanied the project from its instigation phase and made sure that our checklist was followed during execution and publication. We observed mutual impact: While the PBK model itself became significantly more suitable to be applied in regulatory environments, the feedback we received from the regulatory community also clearly showed that by exposing the checklist protocol together with the original research, visibility and consideration of the model were increased. We conclude that both parties can profit from a formal approach when bridging the gap between science and policy affairs.

### **P03.3320. Removing Outside Contamination from Individual Hair Strands for Use in Retrospective Exposure Assessments**

Chelsi White

*Chelsi White<sup>1</sup>, Boris Reiss<sup>1</sup>*

*1. Environmental Health Sciences, The University of Arizona, Tucson, AZ, United States.*

Abstract: Analysis of bulk hair samples suggests that individual strands are suitable biomarkers of past exposures to metals such as Pb, Hg, and Mn. Laser ablation with inductively coupled plasma spectrometry (LA-ICPMS) allows compositional analysis of hair strands along their shaft. Outside contamination on a hair strand is difficult to remove with traditional washing procedures. We have developed a new method to address the issue of outside contamination. We coated two unwashed hair strands with epoxy and laser ablated three 40  $\mu\text{m}$  diameter holes (one at each end and one in the center) through the epoxy-encased hair. Ionized material was analyzed with ICP-MS for the 15 most common isotopes in hair (98% of typical hair composition). The created depth profiles were inspected for signal changes consistent with drilling through epoxy, drilling through hair, and drilling through epoxy again. Five isotopes ( $^{24}\text{Mg}$ ,  $^{55}\text{Mn}$ ,  $^{63}\text{Cu}$ ,  $^{66}\text{Zn}$ ,  $^{208}\text{Pb}$ ) showed similar response changes of at least five orders of magnitude, consistent with expected changes associated with drilling through epoxy and then transitioning from epoxy to hair, hair to epoxy, and passing through the core. The data suggests that (a) measurements taken inside and outside a hair strand can be separated, (b) a hair strand loses approximately 40% of its diameter over 12 months of growth, and (c) the concentration of an element in hair can be estimated using the total isotope counts and the counts of a metal of interest. Outside contamination can be identified when hair strands are analyzed with LA-ICPMS by using our approach of encasing individual hair strands with epoxy. Collecting the top 15 isotopes that encompass a typical hair strand allow calculation of the concentration of trace metals in hair. The substantial material loss of hair during its over time allows for signal composition and suggests further research to identify the maximum time period that hair can be used for retrospective exposure assessment.

### **P03.3330. Analysis of Urinary Biomarkers for Early-Life Exposure to Organophosphate Pesticides and Pyrethroids**

Xianyu Wang

*Xianyu Wang<sup>1</sup>, Yan Li<sup>1</sup>, Chang He<sup>1</sup>, Geoff Eaglesham<sup>1</sup>, Leisa-Maree Toms<sup>2</sup>, Peter Sly<sup>1</sup>, Jochen Mueller<sup>1</sup>*

*1. The University of Queensland, Brisbane, QLD, Australia.*

*2. Queensland University of Technology, Brisbane, QLD, Australia.*

**Abstract:** Organophosphate pesticides (OPs) and pyrethroids (PYRs) are widely used for pest control. Exposure to these chemicals has been linked to various negative health outcomes, particularly for young children. Urinary metabolites are commonly used biomarkers of exposure for non-persistent chemicals such as OPs and PYRs. A method is established for quantitatively measuring these biomarkers in human urine samples. Non-specific OP metabolites dialkylphosphates (DAPs; 6 compounds) are analysed using a lyophilisation method coupled with a subsequent derivatisation procedure using pentafluorobenzyl bromide. Samples are analysed using a gas chromatography coupled to triple quadrupole mass spectrometer. Other chemicals (13 compounds) are analysed via solid phase extraction using hydrophilic-lipophilic balance cartridges after hydrolysed by glucuronidase. Target compounds are analysed using liquid chromatography coupled to tandem mass spectrometry. Synthetic urine is prepared and used as blank samples. Method detection limit (MDL) is calculated as average of the levels in blank samples plus three times the standard deviation and ranges from 0.0083 to 0.83  $\mu\text{g L}^{-1}$  in urine depending on compounds. Quality control (QC) samples are prepared by fortifying the synthetic urine with target compounds. Accuracy of the method is evaluated as the ratio of calculated levels against expected levels and ranges from 0.68 - 1.4. Method precision is expressed as the relative standard deviation of calculated levels from replicated QC samples ( $n=15$ ) and is generally lower than 20%. The method is then applied to the analysis of 20 pooled urine samples from general Australian population, which are stratified into 5 age strata (0-1, 1-2, 2-3, 3-4, and 4-5 years) and two gender strata (2 $\times$ males and 2 $\times$ females). The highest mean concentration is measured for 3,5,6-trichloro-2-pyridinol (TCPy, 12  $\mu\text{g L}^{-1}$  urine). Significant trend of concentrations by age ( $P<0.05$ ) is observed for various OP and PYR metabolites.

### **P03.3340. High Flag Guidance Range Proposal for Urinary Inorganic Arsenic in the Canadian Population**

Marie-Hélène Bourgault

*Marie-Hélène Bourgault<sup>1</sup>, Fabien Gagnon<sup>1</sup>, Michelle Gagné<sup>1</sup>, Mathieu Valcke<sup>1</sup>*

*1. Institut National de Santé Publique du Québec, Montreal, QC, Canada.*

**Abstract:** Background/Aim: A high flag is the concentration of a given biological marker above which a participant should be informed in writing of his/her exposure results and receive information and general advice to help determine, and if necessary control, the sources of exposure. The objective of this study was to propose a guidance biomonitoring value that could be used as a high flag for summed urinary inorganic arsenic species and their metabolites ( $\Sigma$ As), as measured in the Canadian Health Measure Survey. Methods: The starting premise of this work is that the Canadian maximum acceptable concentration (MAC) of 10  $\mu\text{g/L}$  for arsenic in drinking water corresponds to a level of exposure that should not be exceeded. Thus, the urinary  $\Sigma$ As concentration in a population consuming drinking water contaminated at the MAC, and exhibiting a background exposure level similar to what is observed in the Canadian population, was estimated. To do so, data describing the relationship between the urinary excretion of  $\Sigma$ As and the As content of drinking water were retrieved from a literature review. Due to the limited number of relevant studies ( $n=8$ ) and their related uncertainties, a range of significant values of interest was identified. Results: Individuals exposed to arsenic at the background level present in Canada and, additionally, to a water source contaminated at the Canadian MAC of 10  $\mu\text{g/L}$  would have, on average, a urinary  $\Sigma$ As concentration of between 7.5 and 13.3  $\mu\text{g/L}$ . These values are therefore proposed here as respectively the lower and upper limit of a high flag guidance range. Conclusions: This high flag range appears suitable to other population biomonitoring studies around the world in which the background exposure is comparable to the Canadian context. Before selecting a single value from within the proposed range, it will be important to assess the consequences that the determination of a threshold could have on the management and communication of the biomonitoring results.

**P03.3350. Toxic Metals, PFAS and PCBs in Blood and Urine Specimens Collected from New Jersey Clinical Laboratories and Blood Banks**

Zhihua (Tina) Fan

*Zhihua (Tina) Fan<sup>1</sup>, Chang Ho Yu<sup>1</sup>, Eric Bind<sup>1</sup>, Douglas Haltmeier<sup>1</sup>, Collin D. Riker<sup>1</sup>, Jhindan Mukherjee<sup>1</sup>, Songyan Du<sup>1</sup>, Bahman Parsa<sup>1</sup>*

*1. NJDOH, Ewing, NJ, United States.*

**Abstract:** New Jersey (NJ) residents are disproportionately exposed to various hazardous chemicals due to the high density of industry, traffic, and commercial sources. Statewide biomonitoring data are needed to establish a baseline of exposure and to identify potential populations at risk. However, it is costly and laborious to implement a population-based sampling, such as the approach implemented by the National Health and Nutrition Examination Survey (NHANES) for general US population. NJ Department of Health (NJDOH) conducted biomonitoring for toxic metals, polychlorinated biphenyls (PCBs), and emerging pollutants perfluoroalkyl and polyfluoroalkyl substances (PFAS) using a cost-effective alternative approach, i.e. measure target contaminants in remnant specimens collected by clinical laboratories and blood banks in NJ. This project aims to assess the distribution of toxic metals in 3000 blood and 1000 urine specimens, PCBs and PFAS in 1000 sera for NJ adults (20-74 years old). From 2015 to 2017, the study has measured 3 toxic metals in 1760 blood specimens, 5 toxic metals in 218 urine specimens, 12 PFAS in 488 sera, and 40 PCBs in 220 sera. Preliminary data showed most analytes fell within the concentration ranges reported by NHANES. However, some pollutants, such as PFNA (GM [CI]=0.82 [0.78-0.85] NJ, 2016-2017 ng/mL), are elevated compared to the US general population (GM [CI]NHANES, 2013-2014=0.69[0.63-0.75] ng/mL); some surprisingly high results were observed for blood lead (e.g. 50.4 and 26.3 µg/dL) and mercury (several in the 20-30 µg/L range and one in 128 µg/L), and several PCBs showed higher levels than national averages. In-depth analyses are being conducted to examine whether body burdens of NJ adults are significantly higher than national levels and whether there are significant differences by age, gender, race/ethnicity, and geographic location. Through these analyses, NJDOH will identify potentially at-risk subpopulations for further exposure assessment.

**P03.3360. Unexpected, Ubiquitous Exposure in Brazil to Diisopentyl Phthalate, One of the Most Potent Antiandrogenic Phthalates**

Holger Koch

*Holger M. Koch<sup>1</sup>, Michele Bertoncello Souza<sup>2</sup>, Marcella T. Passoni<sup>3</sup>, Claudia Pälme<sup>1</sup>, Katlyn B. Meyer<sup>2</sup>, Amanda C. Venturelli<sup>2</sup>, Giulia Araújo<sup>2</sup>, Rosana N. Morais<sup>2</sup>, Paulo R. Dalsenter<sup>3</sup>, Shanna H. Swan<sup>4</sup>, Anderson J. Martino-Andrade<sup>2</sup>*

*3. Department of Pharmacology, Federal University of Paraná, Curitiba, Brazil.*

*4. Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, NY, United States.*

Abstract: Human exposure to phthalates and other non-persistent chemicals in emerging market countries is largely unknown. A preliminary analysis of urine samples from pregnant Brazilian women indicated the presence of metabolites of Diisopentyl phthalate (DiPeP). Because of its chemical structure, DiPeP is probably located in the hot-spot of phthalate toxicity. In a rapid approach we tried to identify the origin of DiPeP exposure, reliably quantify specific DiPeP metabolites in human urine for exposure assessment and investigate the antiandrogenic potency of this phthalate in rats. We identified iso-amyl alcohol from sugar cane based ethanol production (fossil fuel replacement) as the feedstock for DiPeP production. We modified our phthalate method to include the primary DiPeP metabolite, monoisopentyl phthalate (MiPeP), and two oxidized metabolites (3OH-MiPeP and 4OH-MiPeP). We applied this method to a pilot pregnancy cohort from Curitiba, Brazil (50 urine samples from early pregnancy and 44 gestational pool samples). We could quantify DiPeP metabolites in nearly all (98%) of the early pregnancy and in all gestational pool samples with a median for MiPeP of 3.65 and 3.15 µg/L, respectively, and for the two oxidized metabolites between 1.00 and 1.70 µg/L. All urinary DiPeP metabolites were strongly correlated ( $r=0.89$  to  $0.99$ ). In a parallel approach, we orally exposed pregnant rats to DiPeP and Di-n-butyl phthalate (DnBP; reference phthalate) from gestation day 14 to 18 and measured ex vivo fetal testis testosterone production. We found the effective dose (mg/kg/day) inhibiting fetal testosterone production by 50% (ED50 [95% CI]) for DiPeP (93.6 [62.9-139.3]) to be significantly lower than for DnBP (220.3 [172.9-280.7]), confirming the strong antiandrogenic potency of DiPeP. The surprising and ubiquitous DiPeP exposure in Brazil sparks considerable concern and highlights the need to monitor also "uncommon" but toxic phthalates in worldwide population studies.

### **P03.3370. Toxicokinetic Modeling of Biomarkers of Exposure to Lambda-Cyhalothrin for Predicting Exposure and Determining Biological Reference Values**

Jonathan Côté

*Jonathan Côté<sup>1</sup>, Michèle Bouchard<sup>1</sup>*

*1. Department of Environmental and Occupational Health, University of Montreal, Montreal, QC, Canada.*

**Abstract:** A multi-compartment toxicokinetic model was developed to predict the time courses of the widely used pyrethroid lambda-cyhalothrin and its metabolites (CFMP and 3-PBA) in the human body and in accessible biological matrices following different exposure scenarios. Model parameters were determined using blood and urinary time course data of metabolites (CFMP and 3-PBA) in volunteers exposed to lambda-cyhalothrin by the oral and dermal routes. The modeling confirmed that the kinetics of biomarkers of exposure to lambda-cyhalothrin was similar to that of permethrin and cypermethrin metabolites. For the oral route, the model conceptual and functional representation is similar to the one previously developed by our team for permethrin and cypermethrin. However, representation of the dermal route has been improved to account for the metabolism of the pesticide in the skin by carboxylesterases. The model can be used to simulate single, multiple or continuous exposure scenarios, and multiple and/or simultaneous exposure pathways (oral, dermal or inhalation). Modeling was further used to derive biological reference values (BRVs) for the specific metabolite of lambda-cyhalothrin (CFMP) not to exceed to prevent health effects based on simulations of an exposure to the lambda-cyhalothrin reference dose values (RfD) established by the U.S. Environmental Protection Agency (0.0025 mg/kg bw/day for acute exposure and 0.001 mg/kg bw/day for chronic exposure). The BRV derived for an acute exposure scenario was 199 pmol/kg bw/day or 0.2 nmol/kg bw of CFMP in a 24 h urine collection, which corresponds to 0.9 µmol/mol creatinine. The BRV simulated for a chronic exposure scenario was 0.08 nmol/kg bw/day or 0.3 µmol/mol creatinine.

### **P03.3380. Method Validation for Analysis of Parabens and Antimicrobials in Human Hair**

Hyojong Park

*Hyojong Park<sup>1</sup>, JeongSun Lee<sup>1</sup>, Seokhwan Jung<sup>1</sup>, Younglim Kho<sup>1</sup>*

*1. Department of Health, Environment & Safety, Eulji university, Gyeonggi-do, Korea (the Republic of).*

**Abstract:** Background/Aim Humans are constantly exposed to new chemicals. Among them, harmful substances are also included. EDCs affect human hormones and interfere with the endocrine system. Representative EDCs include parabens and antimicrobials. Samples of blood, serum, and urine are typically used to assessment of human exposure to EDCs. These samples are not adequate to reflect long-term exposure. Hair sample has been used for chronic and past exposure assessments in drug, doping and forensic studies. In this study, we investigate the possibility of biomonitoring through hair, and established pretreatment and analytical method for EDCs in hair. Methods A recovery test was conducted to establish six parabens and two antibacterial agents in hair. Hair samples (0.05g) were pretreated through LLE extraction with methanol (2mL), after added IS and STD. Quantitative analysis was performed using UPLC-MS/MS. Intra (n=7) and Inter (3day) validation were conducted to verify the validity of pretreatment and analytical method. Results As a result of the validation, accuracy were 34.4 ~ 110.4 % (inter) and 68.9 ~ 112.9 % (intra). Precision were 2.1 ~ 36.9 % (inter) and 2.1 ~ 21.7% (intra), and LOD were 0.108 (benzylparaben)~ 0.864(triclosan) ng/ml respectively. Conclusions EDCs biomonitoring by hair analysis will help us to overcome the difficulties in sampling from infants and long-term exposure assessment.

**P03.3390. Main Progress of the 3rd Stage Korean National Environmental Health Survey (2015-2017)**

Ji-Young Yoo

*Ji-Young Yoo<sup>1</sup>, Suejin Kim<sup>1</sup>, Wookhee Choi<sup>1</sup>, Yongwook Baek<sup>1</sup>, Chul Woo Lee<sup>1</sup>, Seung Do Yu<sup>1</sup>*

*1. National Institute of Environmental Research(NIER), Incheon, Korea (the Republic of).*

**Abstract: Background/Aim** With the enactment of the Environment Health Act in 2008, the Korean National Environmental Health Survey(KoNEHS) has been repeatedly carried out since 2009. The KoNEHS is a nationwide biomonitoring survey and aims to monitor trends in exposure of Koreans to environmental chemicals. 32 environmental chemicals have been measured among 18,956 Koreans from the KoNEHS(2009-2017). **Methods** In the 3rd survey(2015-2017), we expanded the scope of target population to cover children(over 3 years old) and adolescents as well as adults. The sampling units for children and adolescents were stratified by area, school grade, and age, and 127 schools and 56 kindergartens and daycare centers were selected randomly. The sampling units for adults followed the same sampling strategy from the 1st and 2nd Surveys and 233 sampling units were selected. 26 environmental chemicals were measured in bio-samples of subjects. **Results** 6,167 subjects participated including 1,458 children, 922 adolescents and 3,787 adults. The proportion of males to females was 45.6% (2,815) to 54.4% (3,352), respectively. Urinary Bisphenol A concentrations decreased with increasing age. Urinary Bisphenol A levels in Korean adults tend to increase in the past 9 years whereas urinary phthalate metabolites levels tend to decrease. **Conclusions** Data collected from the past 9 years have been an important resource to figure out the environmental exposure and its effects on health. The representative levels of environmental chemicals has been announced as government-approved statistics. Based on the comprehensive evaluation of the 9-year study, the 4th Survey(2018-2020) has been planned and is underway.

### **P03.3400. LC-HRMS Biomarker Suspect Screening in Low Dose Studies**

Daniel Bury

*Daniel Bury<sup>1</sup>, Frederik Lessmann<sup>2</sup>, Kathrin Papadopoulos<sup>1</sup>, Alexandra Nehring<sup>1</sup>, Tobias Weiss<sup>1</sup>, Heiko Hayen<sup>3</sup>, Thomas Brüning<sup>1</sup>, Holger M. Koch<sup>1</sup>*

*1. Institute for Prevention and Occupational Medicine of the German Social Accident Insurance - Institute of the Ruhr-Universität-Bochum (IPA), Bochum, Germany.*

*2. Institute for Occupational and Maritime Medicine (ZfAM), University Medical Center Hamburg-Eppendorf, Hamburg, Germany.*

*3. Institute of Inorganic and Analytical Chemistry, University of Münster, Münster, Germany.*

Abstract: Exposure biomarker development is a time consuming procedure, starting with identification of presumably appropriate metabolites of the xenobiotic in question. Investing into unsuitable biomarker candidates (i.e. metabolites which are formed in low proportion or are not formed at all) can be costly. Accordingly, efficient strategies for the identification of promising biomarker candidates are needed. For this purpose, liquid chromatography coupled with high resolution mass spectrometry (LC-HRMS) is often applied for metabolite screening in in vitro and animal in vivo screening approaches, typically involving high doses/concentrations of the xenobiotic. Given the limitations of in vitro models and interspecies differences in metabolism, we sought to improve the certainty of metabolite screening by analyzing urine samples from human studies with low oral dosing (i.e. toxicologically uncritical). Metabolite screening was performed by LC-Q-Orbitrap-MS combined with a commercial data mining software. Identification criteria were plausible excretion kinetics, product ion spectra, <sup>13</sup>C isotopomer ratios, and retention times. We present results of a pilot study, which identified nine metabolites of the plasticizer di (2-ethylhexyl) terephthalate (DEHTP). Three of them (5OH-MEHTP, 5Oxo-MEHTP, and 5cx-MEPTP) are already established biomarkers of DEHTP exposure. Five additional, specific metabolites have not been described previously. In another example we successfully identified several tentative metabolites of the UV filter avobenzene. However, we also report examples, in which metabolite identification did not succeed by this approach (e.g. the plasticizer DEHA) and we highlight influencing factors (such as mobile phase pH, in source adduct formation and fragmentation) possibly leading to wrong conclusions. The presented approach is a valuable but not universal tool for biomarker development. In some cases, a more sensitive triple quadrupole screening can be superior.

**P03.3410. Determinants of Xenoestrogen Exposure and Implications on Inter- and Intra-Variation of Urinary Biomarkers across Individuals**

Cristina Martin

*Cristina Martin<sup>1</sup>, Dany Chhan<sup>1</sup>, Krystal J. Pollitt<sup>1</sup>*

*1. Environmental Health Sciences, University of Massachusetts, Amherst, MA, United States.*

Abstract: Exposure to xenoestrogens such as parabens, bisphenols, triclosan and triclocarban is ubiquitous given their widespread use in consumer products. Spot urine samples provide a snapshot of chemical exposure concentrations at one point in time. The extent of variation exhibited by an individual in relation to the overall variability observed across a population is unclear. The objective of this study was to evaluate the exposure of healthy adults living in Western Massachusetts to a panel of xenoestrogens and investigate inter- and intra-individual variability as well as potential predictors of exposure. In this study we present results from an intensive biomonitoring campaign where morning (09:00) and evening (17:00) urine samples were collected from 10 participants over a 5-day period. Samples were prepared for analysis by liquid chromatography coupled with electrospray ionization tandem mass spectrometry (LC-ESI-MS/MS) using solid phase extraction. Concentrations of eight environmental xenoestrogens, including parabens (methyl-, ethyl-, propyl-, butyl-), bisphenol-A (BPA), bisphenol-S (BPS), triclosan and triclocarban were measured in urine in their unconjugated and conjugated forms. Hourly inventories of consumer and personal care product use, thermal paper handling as well as water and food consumption were also collected from participants. The association between these potential exposure factors and concentrations of xenoestrogens measured in urine were evaluated. Our optimized solid phase extraction procedure and MS/MS parameters achieved good sensitivity and recoveries ranging from 85 to 105%. Variability of creatinine adjusted paraben, BPA, BPS, triclosan and triclocarban concentrations in urine measured within and between individuals will be presented. Potential exposure sources will further be discussed.

### **P03.3420. Using the Comparative Toxicogenomics Database to Further Our Understanding of Environmental Exposures on Human Health**

Cynthia Grondin

*Cynthia J. Grondin<sup>1</sup>, Allan P. Davis<sup>1</sup>, Jolene A. Wieggers<sup>1</sup>, Thomas C. Wieggers<sup>1</sup>, Carolyn J. Mattingly<sup>1</sup>*

*1. Biology, North Carolina State University, Raleigh, NC, United States.*

Abstract: The Comparative Toxicogenomics Database (CTD; <http://ctdbase.org>) is a freely available resource that promotes understanding about the mechanisms by which environmental exposures influence human health. Four categories of content are manually curated from the literature: toxicogenomics (chemical-gene interactions), diseases (chemical-disease and gene-disease associations), phenotypes (chemical-induced phenotypes), and exposure data (environmental stressor-receptor-event-outcome relationships). Exposure details, including stressor source, receptor age, sex, smoking status, biomarker levels, correlations with disease or phenotypes, and geographic location are also recorded. In our curation paradigm, controlled vocabularies, ontologies, mnemonic codes and structured notation are used to transform the literature into a semantic, computable structure, enabling integration among the four categories as well as with gene attributes, molecular pathways, species, and general toxicology information to provide a knowledgebase of over 36 million toxicogenomic relationships. These data can be explored with queries and analytical tools to inform hypothesis development connecting chemicals/drugs, genes/proteins, diseases/phenotypes, taxa, functional annotations, pathways, and population-based exposure events. In addition, they provide unique opportunities to generate predictive adverse outcome pathways (connecting chemical-protein molecular initiating events, key phenotype events, adverse diseases, and population-level health outcomes) as well as aggregate exposure pathways (relating real-world measurements of environmental stressors and biomarkers to demographics). CTD's centralization of exposure science data, integration with chemical-gene, disease and phenotype modules, and additional analysis tools provide a unique resource to advance our understanding of the molecular mechanisms of action by which environmental exposures affect human health.

### **P03.3450. Exposure to N,N-diethyl-m-toluamide (DEET) in the U.S. Population: 2007-2014**

Maria Ospina

*Maria Ospina<sup>1</sup>, Lee-Yang Wong<sup>1</sup>, Samuel Baker<sup>1</sup>, Amanda Bishop Serafim<sup>1</sup>, Pilar Morales-Agudelo<sup>2</sup>,  
Antonia Calafat<sup>1</sup>*

*1. CDC, Atlanta, GA, United States.*

*2. Battelle Memorial Institute, Atlanta, GA, United States.*

**Abstract:** Introduction: N,N-diethyl-m-toluamide (DEET) is the most widely used insect repellent in the USA with more than 500 DEET-containing products registered with the EPA. DEET is effective against disease-carrying vectors such as ticks and mosquitoes associated with Lyme disease, malaria, encephalitis, Dengue fever, West Nile, Chikungunya and Zika viruses. We have collected data from four National Health and Nutrition Examination Survey (NHANES) cycles (2007-2014) for urinary concentrations of DEET and two of its metabolites 3-(diethylcarbamoyl)benzoic acid (DCBA) and N,N-diethyl-3-hydroxymethylbenzamide (DHMB). Methods: We measured urinary concentrations of DEET and two of its metabolites in 10,362 Americans 6 years and older from the 2007-2014 NHANES. We used multiple regression to examine associations between concentrations of DCBA, the most detected DEET biomarker, throughout the years, and age, sex, race/ethnicity, and season of year. Results: DCBA was the most frequently detected biomarker (86%) with concentrations ranging from 0.33-382,000 µg/L; by contrast, DHMB was only detected in 14% (concentration range: 0.06-11,400 µg/L). For all age groups, DCBA adjusted geometric mean concentrations varied upon season of the year, being higher in summer than in winter. DCBA concentrations decreased significantly from 2007-2008 to 2013-2014 for samples collected during the winter months with the largest decrease observed among people older than 60 years of age. Conclusions: Exposure to DEET was prevalent in the general U.S. population in 2007-2014. Higher concentrations of DCBA, a reliable biomarker of exposure to DEET, in the warm season agree with increasing use of DEET when people usually spend time outdoors for recreational activities; also pests are more abundant with higher seasonal temperatures, and DEET can provide additional protection against vector borne diseases in warmer weather.

### **P03.3460. Prenatal Fluoride Exposure and Symptoms of Attention Deficit Hyperactivity Disorder (ADHD)**

- 7. Instituto Nacional de Salud Pública, Cuernavaca, Mexico.*

**Abstract:** INTRODUCTION: Epidemiologic and animal-based studies have raised concerns about the potential neurotoxicity of fluoride exposure as manifested by deficits in IQ and problems with attention. To date, no prospective epidemiologic studies have examined the effects of prenatal fluoride exposure using fluoride biomarkers and sensitive measures of attention. OBJECTIVE: To test the association between prenatal fluoride exposure and symptoms associated with attention-deficit and hyperactivity disorder (ADHD) in 213 Mexican children aged 6-12 years old enrolled in the Early Life Exposures in Mexico to Environmental Toxicants (ELEMENT) birth cohorts between 1997 to 2006. METHOD: We measured urinary fluoride levels during pregnancy and adjusted them for urinary creatinine (MUFcr). The Conners' Rating Scales-Revised (CPRS-R) was completed by mothers as a behavioural measure of attention problems, and the Conners' Continuous Performance Test (CPT-II) was administered to each child to assess sustained attention and inhibitory control. We used gamma regression analyses to examine associations between MUFcr and measures of attention, adjusting for covariates. RESULTS: The mean MUFcr level for all women was 0.85 mg/L (95% CI: 0.81, 0.90) and the Interquartile Range (IQR) was 0.46. In multivariate-adjusted models, a 0.5 mg/L increase in MUFcr (approximately IQR) corresponded to significantly higher CPRS-R scores for DSM-IV Inattention (2.84 points, 95% CI: 0.84, 4.84); Cognitive Problems and Inattention, (2.54 points, 95% CI: 0.44, 4.63), DSM-IV Total ADHD Index (2.38 points, 95% CI: 0.42, 4.34) and ADHD Index (2.47 points; 95% CI: 0.43, 4.50). The shape of the associations suggested a possible ceiling effect. No significant associations were found with outcomes on the CPT-II. Sensitivity analyses did not appreciably alter the results. CONCLUSION: Higher levels of prenatal fluoride exposure were associated with higher symptoms of ADHD measured by CPRS-R in the offspring at age 6-12 years.

### **P03.3470. Proteomic Array Analysis of an Epithelial Cell Model Infected with Cryptosporidium**

Eunice Varughese

*Eunice Varughese<sup>1</sup>, Emily Wheaton<sup>1</sup>*

*1. U.S. EPA, Cincinnati, OH, United States.*

**Abstract:** Cryptosporidiosis is a human diarrheal disease caused by the etiological agent *Cryptosporidium*. This parasite abounds in the environment in resistant oocyst form and can cause life-threatening consequences in immunosuppressed individuals. By evaluating the fundamental mechanisms of pathogenesis in the host, it is helpful to deduce proteins involved in virulence. Parasite-induced host cell signaling events and subsequent cytoskeletal remodeling were investigated by using cultured human ileocecal carcinoma epithelial (HCT-8) cells inoculated with *C. parvum* sporozoites. Although many efforts have been made to characterize gene expression changes, these changes may not necessarily reflect changes in protein expression within an infected cell. New applications in proteomic arrays have the added benefit of studying changes in protein expression and functionality. In this study, we use a protein array platform to observe changes in protein expression and function when host cells are infected with *C. parvum* sporozoites. Previous studies have shown that the invasion of epithelial cells involves host-signaling whereby host cell actin reorganization allows for the enveloping of the parasite. A major signaling pathway implicated in actin polymerization involves the activation and deactivation of proteins containing SH2 domains, such as CRKL, PIK3, ABL, and the Src protein tyrosine kinase (PTK) family. Our studies show that a phospho-proteomic array of HCT-8 cells inoculated with the pathogen have a 0.87-fold increase in the phosphorylated form of c-Abl. Moreover, an SH2 proteomic array overlaid with protein lysates from uninfected and infected cells revealed that infected protein lysates had decreased binding (66%) to the SH2 domain of CRKL and increased binding (45%) to the SH2 domain of PIK3. These findings demonstrate a prominent role for proteins that may play a role in formation and stabilization of microvillar protrusions which envelope the pathogen.

**P03.3480. Distinct Fecal Microbiota and Serum Metabolite Profiles in Male Rat Exposed to Aluminum Oxide and Aluminum Oxide Nanoparticles**

Song Tang

*Song Tang*<sup>1</sup>

*1. National Institute of Environmental Health, China CDC, Beijing, China.*

Abstract: The widely application of aluminum oxide nanoparticles (Al<sub>2</sub>O<sub>3</sub> NPs) in industry and personal care products has been raising concerns about their potential adverse consequences. However, the knowledge on their influence on gut microbiota and serum metabolism remains poorly understood. This study employed an integrated approach combining 16S rRNA gene sequencing and untargeted metabolomics profiling to investigate the impact of a 28 days oral exposure to  $\alpha$ - and  $\gamma$ -Al<sub>2</sub>O<sub>3</sub> NPs and the equivalent dose of bulk Al<sub>2</sub>O<sub>3</sub> on the toxic response, fecal microbiota composition and serum metabolites of male rats. At the equal dose of 100 mg/kg bw,  $\alpha$ -Al<sub>2</sub>O<sub>3</sub> NPs had a greater effect on white blood cell count, percent of monocytes, liver SOD activity and plasma GSH content, than that of  $\gamma$ -Al<sub>2</sub>O<sub>3</sub> NPs and bulk Al<sub>2</sub>O<sub>3</sub>. 16S results revealed NPs exposure significantly perturbed the fecal microbiome composition, and the relative abundance of genus such as *Desulfovibrio*, *Steroidobacter* and *Acidibacter* was significantly reduced. A significantly lower alpha diversity and distinct microbial communities, as reflected by beta diversity, were observed in  $\alpha$ -Al<sub>2</sub>O<sub>3</sub> NPs treatment, compared to bulk Al<sub>2</sub>O<sub>3</sub> and control. UHPLC-QTOFMS indicated that the circulating serum metabolites (e.g. 3-hydroxyisovaleric acid, dopamine, D-glucuronate) were significantly more abundant with  $\alpha$ -Al<sub>2</sub>O<sub>3</sub> NPs, while metabolites (e.g. corticosterone, glycerol, glycerol 3-phosphate) were significantly induced by  $\gamma$ -Al<sub>2</sub>O<sub>3</sub> NPs. Pathway analysis further indicated potential defects in the D-glutamine and D-glutamate metabolism and phenylalanine, tyrosine and tryptophan biosynthesis in  $\alpha$ -Al<sub>2</sub>O<sub>3</sub> NPs, while glycerolipid and linoleic acid metabolism were significantly affected by  $\gamma$ -Al<sub>2</sub>O<sub>3</sub> NPs. This study provides novel insights regarding the differential fecal microbiome and serum metabolome affected by nanoparticulate forms versus bulk forms of aluminum oxide in organisms.

**P03.3490. Factors Associated with Hair Nicotine Concentration: A Cross-Sectional Study in Children from Santiago, Chile**

Veronica Iglesias

**Abstract:** Introduction: Exposure to secondhand tobacco smoke (SHS) is a world public health concern. Children are a vulnerable group. Accumulated exposure could increase health risks. The aim was to evaluate exposure to SHS in children measured through hair nicotine concentrations and its association with home air nicotine concentrations. Methods: Cross-sectional design study in schoolchildren between 6 and 8 y.old. A trained interviewer applied a standardized questionnaire to the mother, took the child's hair sample and placed a passive monitor in the living room to measure the indoor air nicotine concentration during 7 days. The association between air nicotine and hair nicotine was evaluated with logistic regression models. Results: 184 children were evaluated, 58.7% were female, 38.5% hair nicotine concentrations were above the limit of detection (LD) (0.058 ng/mg). When we measure air nicotine concentrations, 9.1% of the samples were above the limit of detection (0.026 ug/m3). We dichotomized both variables (over and below LD). Factors associated with detectable air nicotine concentrations were frequency of tobacco consumption (does not smoke (reference), some days OR=4.71; 95%CI 0.99-22.22, every day OR=12.62; 95%CI 3.25- 48.96); parental tobacco use within the household OR=13.68;95%CI 4,35- 43,11; parental tobacco use outside the home OR=5,46;95%CI 1,94-15,41. We found a significant association between hair nicotine concentrations and air nicotine concentrations after adjusting by age, sex and type of school (public/ private as proxy of socioeconomic level) (OR= 3.13; 95%CI 1.09-8.99). Conclusion: Considering that home is the main source of exposure, that children are exposed involuntarily and that there is human evidence linking SHS with cancer and other acute and chronic diseases, it is urgently needed to sensitize parents on the risks of exposure to SHS and to facilitate the adoption of preventive strategies such as smoke-free homes in the homes of smoking parents.

### **P03.3500. Enhanced Passive Surveillance Methods Using CDC and State Child Blood Lead Surveillance Data**

Tim Dignam

*Tim Dignam<sup>1</sup>, James Hodge<sup>1</sup>, Stella Chuke<sup>1</sup>, WD Flanders<sup>1</sup>*

*1. cdc, Atlanta, GA, United States.*

Abstract: Local, state and national child blood lead level (BLL) surveillance is typically conducted passively. The increasing need to detect increases in the proportion of elevated child BLLs from surveillance data have highlighted the need for methods to detect and investigate changes of public health importance in a timely manner. Our objective was to develop and assess a modified Cumulative Summary (CUSUM)/Shewhart chart alerting algorithm for analysis of child BLL surveillance data that can be applied continually to improve the time to detect changes in reported BLL surveillance patterns. Geographic and temporal data-aggregation strategies were applied on routinely collected child BLL surveillance data employing an alerting algorithm using a sliding buffer concept. The algorithm accounts for long term trends, seasonal variation and serial autocorrelation of child BLLs. The algorithm was applied on 20 jurisdictions: two with a known increase in the proportion of children < 6 years of age with BLLs  $\geq 5$   $\mu\text{g}/\text{dL}$  and data from 18 randomly selected counties from the CDC Child Blood Lead Surveillance System. Alert signals retrospectively identified time periods in the two jurisdictions where a known increase occurred. No signals were identified among 17/18 (94.4%) randomly selected counties where no known changes occurred. The one county where a signal was identified appears appropriate to the data patterns, where a 67% decrease of children < 6 years of age tested occurred from the previous year. The algorithm accomplished adjustment for seasonality and de-trending. The modified algorithm provides a framework for enhanced passive surveillance by identifying changes in proportion of children w/ BLLs  $\geq 5$   $\mu\text{g}/\text{dL}$ . Algorithm settings are empirical and need to be set at the local level. The algorithm methodology needs replication at the local level. Further study is required to define alerting signal triggers when considering public health action compared with statistical significance.

### **P03.3510. Factors Associated with Low Level of Urinary Inorganic Arsenic Concentration**

Veronica Iglesias

*2. SEREMI de Salud Arica y Parinacota, Arica, Chile.*

**Abstract:** Introduction: Population in Arica's city has been exposed to arsenic of natural and anthropogenic origin. In 2009, an environmental health center was created in order to surveillance exposure to polimetals, provide medical care to exposed population and propose intervention measures. Objective: To assess factors that predict the urine arsenic concentration in population served at the environmental health center in the period 2009-2015. Method: The population analyzed was recruited at the environmental health center of Arica, Chile between 2009 and 2015. The database provided included sociodemographic information, dwelling characteristics, urinary inorganic arsenic concentration and creatinine. We conduct linear regression analysis to assess association with variables included in final model. Results: Complete data was available for 10.437 people. The geometric mean of inorganic arsenic was 17.4 µg/L (min 1.99, max 477 µg/L). The variables that explained the urine inorganic arsenic concentration were urinary creatinine ( $\beta$  1.86 CI95% 1.82-1.91), alcohol consumption ( $\beta$  1.24 CI95% 1.00-1.53), drinking water consumption ( $\beta$  1.07 CI95% 1.04-1.11), the household material ( $\beta$  1.10 CI95% 1.03-1.17) and the soil discovered in yard ( $\beta$  1.01 CI95% 1.00-1.10). Conclusion: Although we identified variables that were significantly associated with urine arsenic concentration, they explain in a low proportion the arsenic variability. It is necessary to extend the study to identify variables that allow propose intervention measures to reduce exposure.

### **P03.3520. Shorter Gestation Is Associated with Renal Biomarkers at 4 Years**

Yuri Levin-Schwartz

*Yuri Levin-Schwartz<sup>1</sup>, Paul Curtin<sup>1</sup>, Katherine Svensson<sup>1</sup>, Chris Gennings<sup>1</sup>, Daniel Flores<sup>1</sup>, Lisa Satlin<sup>1</sup>, Ivan Pantic<sup>2</sup>, Andrea Baccarelli<sup>3</sup>, Martha M. Téllez-Rojo<sup>4</sup>, Robert Wright<sup>1</sup>, Alison P. Sanders<sup>1</sup>*

*3. Columbia University, New York, NY, United States.*

*4. National Institute of Public Health, Cuernavaca, Mexico.*

**Abstract:** Studies suggest that exposure to air pollution and heavy metals during pregnancy may contribute to birth outcomes such as shorter gestation. Since nephron development is not typically complete until 36 weeks of gestation, infants born prematurely may be more susceptible to renal dysfunction. Urine proteins reflect renal health and are predictive of kidney function later in life. We explored the association between gestational age (GA) and nine proteins in spot urine samples collected from 103 children aged 4-6 years participating in the Programming Research in Obesity, Growth, Environment and Social Stressors (PROGRESS) cohort in Mexico City. The nine urinary proteins: Albumin, neutrophil gelatinase-associated lipocalin (NGAL), osteopontin (OPN), kidney injury molecule-1 (KIM-1), clusterin, alpha-1-microglobulin, cystatin C, beta-2 microglobulin and trefoil factor 3, were selected based on their use as validated or emerging biomarkers of children's renal health and measured using the Luminex Milliplex System. We applied linear regression to examine associations between GA with individual proteins and used weighted quantile sum (WQS) regression, a statistical method developed to assess mixtures, to create a composite renal biomarker index of all 9 proteins. We adjusted for body mass index, indoor smoking, socio-economic status, age, gender, and urine creatinine. In the individual protein regressions, each day shorter gestation was associated with 12.9% higher KIM-1 (95% CI[-0.00, 24.00],  $p < 0.06$ ) and 4.4% higher cystatin C (95% CI[-0.33, 8.84],  $p < 0.08$ ). As is in the univariate models, the WQS renal biomarker index was associated with shorter gestation (-0.58; 95% CI[-10.09, -0.06],  $p < 0.03$ ). Weights constructed to parse the contribution of each protein to the result showed that albumin (24%), NGAL (19%), OPN (16%) and KIM-1 (16%) had the highest contribution. Motivated by these results, additional work will assess the interactions with environmental exposures.

### **P03.3530. LCMSMS Method to Analyze Metabolite of N-Methyl-2-Pyrrolidone (NMP) and N-Ethyl-2-Pyrrolidone (NEP) in Human Urine**

Patrick Bélanger

*Patrick Bélanger<sup>1</sup>, René Bérubé<sup>1</sup>, Normand Fleury<sup>1</sup>*

*1. CTQ, inspq, Quebec, QC, Canada.*

Abstract: N-methyl-2-pyrrolidone (NMP) and N-ethyl-2-pyrrolidone (NEP) are shown to be embryotoxic and teratogenic.<sup>1-2</sup> These volatile solvents are widely used as industrial solvents in the manufacture of polymers, coating materials, paints, pesticides, cosmetics and pharmaceutical compounds.<sup>2</sup> And then, the population is very exposed. These compounds are quickly metabolised in 5-hydroxy-N-methyl-2-pyrrolidone (5-HNMP) and 5-hydroxy-N-ethyl-2-pyrrolidone (5-HNEP), follow by intermediate species, N-methyl-succinimide (MSI) and N-ethyl-succinimide (ESI). Finally 2-hydroxy-N-methyl-succinimide (2-HMSI) and 2-hydroxy-N-ethyl-succinimide (2-HESI) are produced (3) (4). Fast LCMSMS method based on dilute and shoot sample preparation has been developed and validated to measure the level of exposure after urine collection. A short study on 50 volunteers living in the Quebec City area allow to show that nearly 100% of the population was exposed to these solvents.

### P03. Risk Assessment and Policy 3

#### **P03.3540. The Exposure Science Aspects of the Re-Envisioning of the (U.S.) National Library of Medicine's Toxicology and Environmental Health Resources**

Pertti Hakkinen

*Pertti J. Hakkinen*<sup>1</sup>

*1. National Library of Medicine, National Institutes of Health, Bethesda, MD, United States.*

Abstract: The (U.S.) National library of Medicine (NLM) is a part of the National Institutes of Health (NIH). The NLM in early 2018 began an effort to re-envision its toxicology and environmental health resources. This is the first ever re-envisioning of these resources, covering several decades of existence for some resources. The goal is to optimize NLM's electronic resources in the areas of toxicology and environmental health by assessing and re-envisioning them to ensure that they continue to meet the changing needs of a diverse set of users. The overall coverage of NLM's resources includes chemicals and drugs, diseases and the environment, environmental health, exposure science, occupational safety and health, poisoning, emergency response, risk assessment and regulations, and toxicology. Examples of the users of NLM's toxicology and environmental health resources include academic researchers, government agencies, industry, not-for-profit organizations, and healthcare providers. A workshop of about 45 experts representing a wide range of these types of users was held in April 2018. The workshop provided in-depth insights into the information and services provided by NLM and what is foreseen for the future; It also identified current information sources (from NLM and elsewhere). In addition, it helped to identify critical gaps in the resources NLM offers in order to improve the function, content, and presentation of desired information resources in the future. Further, it provided in-depth insights to thoughtfully inform the development of a new generation of NLM resources. This presentation will focus on the exposure science-related aspects of this NLM re-envisioning effort.

### **P03.3570. Differential Inhalation Toxicity Induced by E-Cigarette Aerosol Flavorings in Association with Nicotine**

Seung-Hyun Cho

*Seung-Hyun Cho<sup>1</sup>, Nalyn Siripanichgon<sup>1</sup>, Jean Kim<sup>1</sup>, Jonathan Thornburg<sup>1</sup>*

*1. RTI International, Research Triangle Park, NC, United States.*

**Abstract:** Significance. There is a significant need for data on respiratory effects of chemical constituents including flavorings in e-cigarettes (EC) aerosols to inform the regulatory science and communicate with the public about EC safety. Methods. Cytotoxicity and inflammatory response of human airway epithelial cells in a submerged culture were measured by MTT and immunoassay at 18 hours post-exposure to EC aerosols collected in an impinger. Aerosols were generated from an EC with heating coil power of 8.9 W using a program-controlled, customized smoking system following CRM No.81 and ISO puffing regimes. Four differently flavored e-liquids (i.e., non-flavor, menthol, sweet, tobacco) of 50:50 propylene glycol and vegetable glycerin with two nicotine concentrations (0% and 1.8%) for each flavor were tested in dose-response manner. Results. We found differential cytotoxicity and repressed immune response associated with flavorings. The menthol-flavored aerosols induced cytotoxicity in dose-response manner with 20% cytotoxicity at the highest dose as compared to the other two flavorings that showed 10% or less. Non-flavored aerosols showed little cytotoxicity that did not vary by dose and nicotine level, suggesting the vehicle and additives other than flavorings have little cytotoxicity for the condition we used to generate aerosols. Very low nicotine dose slightly improved cell viability, agreeing with previous reports in the literature. IL-8 production was reduced with increased dose, but not for menthol or sweet flavors. Conclusion. EC flavorings have a significant impact on the degree and variability of respiratory toxicity. Certain flavoring such as menthol together with nicotine would synergistically increase harmful effects in user's lung. More efforts that investigate the link between flavorings chemical composition in association with nicotine and respiratory health effects are needed to support regulation of harmful constituents in the EC products.

### **P03.3580. Cyanobacteria and Cyanotoxins in Sicilian Freshwater Basins (Italy): A Risk Assessment for Drinking Water**

Pietro Zuccarello

*Margherita Ferrante<sup>1</sup>, Antonio Cristaldi<sup>1</sup>, Mara Stefanelli<sup>3</sup>, Maura Manganelli<sup>2</sup>, Emanuela Testai<sup>2</sup>, Gea Marzia Oliveri Conti<sup>1</sup>, Pietro Zuccarello<sup>1</sup>*

*2. Department of Environment and Health, Istituto Superiore di Sanità, Rome, Lazio, Italy.*

*3. Department of technological innovations and safety of plants, products and anthropic settlements, INAIL, Rome, Lazio, Italy.*

Abstract: The eutrophication of surface waterways led to a rise in harmful cyanobacterial blooms worldwide. Sicily, the biggest Italian region, suffers from a strong drought and a growing scarcity of clean water. Toxin producing Cyanobacteria (CB) in Sicilian dams have been often reported, but they have not been regularly monitored until today. Therefore, health risk associated with cyanotoxins (CTX) in drinking waters remains largely unknown. To prevent urban water crisis in next future, we need to manage all water resources effectively, especially the more dynamic surface freshwater sources. Aim of this study was to monitor the major dams of Sicily used as drinking water supplies to carry out a risk assessment relative to the presence of CB and CTX in raw waters. Seven out of thirty-three Sicilian dams, used as drinking water supply, were monitored seasonally for one year. We collected samples of surface and deep waters. ELISA test was performed to detect sum of CTX microcystins (MCs) and nodularins (NOD). Also, for each sample, CB species were identified. *Planktothrix rubescens*, *Pseudoanabaena* sp., *Limnothrix redekei*, *Borzia* sp., *Merismopedia* sp., *Oscillatoria* sp., *Dolichospermum* sp. Picocyanobacteria were found in the studied basins. Sums of MCs and NOD were detected in each sample and their concentrations ranged between 2 ng/L and 669 ng/L. Presence of toxic CB (especially *P. rubescens*) in Sicilian lakes, whose waters are used for drinking purposes, could represent an important risk for human health. Variability of species in a same basin could lead to the selection of the most harmful one and to increase of MCs in drinking waters. In one year of monitoring we usually detected low concentrations of CTX, but in some cases they were close to the reference value that WHO assessed for drinking water (1 µg/L). Even if LC-MS and molecular confirmation are needed, our results suggest that a more regular and frequent surveillance is necessary to minimize risk for human health.

### **P03.3590. Regulation of Chemicals in Children's Products: How U.S. and EU Regulations Impact Smaller Markets**

Maya Negev

*Maya Negev<sup>1</sup>, Tamar Berman<sup>2</sup>, Shay Reicher<sup>2</sup>, Simona Balan<sup>3</sup>, Anna Soehl<sup>4</sup>, Shula Goulden<sup>5</sup>, Ruti Ardi<sup>6</sup>, Yaniv Shammai<sup>6</sup>, Arlene Blum<sup>7</sup>, Miriam L. Diamond<sup>8</sup>*

- 8. Dept of Earth Sciences, University of Toronto, Toronto, ON, Canada.*

**Abstract:** Background: Children's products may contain trace metals and organic compounds potentially harmful to children's health and development. Intergovernmental organizations and individual countries regulate chemicals in consumer products, but a coordinated international approach is lacking. Aim: To assess how a small market (Israel as a case study) is affected by the regulation of chemicals in children's products in large markets. Methods: We (1) compared regulations of chemicals in children's products in the US, EU and Israel; and (2) tested regulated and unregulated contaminants (trace metals, phthalates, bisphenol A and flame retardants) in six products categories (n=70) with potential for high oral/dermal exposure. Results: Due to the complexity of designing chemical regulation and to avoid trade barriers, Israel adopts product-specific standards that are fragments of complex regulations in large markets, whose impacts therefore extend beyond their territories. Thus, Israel has regulatory gaps because it lacks overarching legislation such as the EU REACH and the US CFR. For example, toys are regulated in Israel, while children's jewelry are not. We found 23% of jewelry samples exceeded the US standard for lead, while no toy samples exceeded the Israeli/EU standard for trace metals. In textiles, baby mattresses and diaper-changing mats, phthalates exceeded the EU standard in 21-45% of samples (mean, by mass: 6.74 % for diisononyl phthalate, 1.32 % for di(2-ethylhexyl) phthalate). Bisphenol A exceeded the EU standard in 14-45% of samples (mean 1.03 ppm). Discussion: While we found compliance with standards for products regulated in Israel, we also found high levels of chemical contamination, exceeding US/EU regulations, in unregulated products. By highlighting the impacts of the lack of a comprehensive regulatory framework, our results have advanced Israeli standards for children's jewelry and facilitated revisions of standards for mattresses and changing mats.

**P03.3600. Comparison of Dermal Exposure across a Diverse Range of Consumer Products Based on Modelling Approaches Commonly Applied to Human Health Risk Assessments under Canada's Chemicals Management Plan**

Cathy Campbell

*Cathy Campbell<sup>1</sup>, Angelika Zidek<sup>1</sup>, Virginie Bergeron<sup>1</sup>*

*1. Health Canada, Government of Canada, Ottawa, ON, Canada.*

Abstract: Canada's Chemicals Management Plan (CMP) is an initiative aimed at reducing the risk posed by chemicals to Canadians and their environment. Since 2006, more than 3000 substances have been assessed in over 260 assessment reports and this work continues in the final phase of the CMP, including integration of novel and emerging approaches where appropriate. Many of the quantitative exposure assessments to date have included products available to consumers, including personal care, household cleaning, do-it-yourself (DIY) and paint products, with exposure characterization derived using modelling tools such as ConsExpo (e.g., for cleaning products, DIY and paint products) and in-house guidance (e.g., personal care products). This poster will present findings from an analysis where dermal exposures were compared and ranked for over 100 consumer products (including mixing/loading, application and post-application activities, as appropriate). The poster will include separate exposure estimates for specific age groups (toddlers, children, teenagers and adults) thus incorporating age-specific differences in amount applied, frequency of applications, and body weight. The results of this analysis can help to prioritize key sources of consumer exposures as well as identify subpopulation of interest over a wide range of uses. This poster will also provide a relative comparison of dermal exposure associated with products as diverse as cleaning products, DIY and personal care products and, where appropriate, may facilitate clustering or grouping of products with similar dermal exposure potential.

### **P03.3610. H2020 Insurance: Health Sector Demo**

Samya Pinheiro

*Samya D. Pinheiro<sup>1</sup>, Christian Witt<sup>2</sup>, Fred Hattermann<sup>3</sup>, Georg Bolke<sup>2</sup>, Peter Hoffmann<sup>2</sup>, Gwendoline Lacressonniere<sup>1</sup>, Celine Deandreis<sup>1</sup>, Larissa Zanutto<sup>1</sup>, Ylva Hauf<sup>3</sup>*

- 3. Potsdam Institute for Climate Impact Research (PIK), Potsdam, Germany.*

**Abstract:** Globally, there is increased concern about the potential impacts of extreme climate events, including their impact on loss and damage to people, assets and property. The Global Insurance Sector is a key actor to implement programs to improve resilience related to environmental risk factors such as the climate extreme events. The H2020 Insurance Project intends to operationalize a system, called the Oasis Loss Modelling Framework, which provides a standardized risk assessment process to assess potential losses, areas at most risk and quantify financial losses. The system will be implemented based on the application of demo for different sectors, including the HEALTH INSURANCE SECTOR. The objective is to help the health insurance sector to understand much more precisely the relation between the air quality, climate extremes and health conditions in a given population. The access to high-resolution data representing the systemic exposure to air pollution and climate extreme events must foster new innovations which will allow a better adaptation to new climatic conditions. Based on morbidity-mortality data and high-resolution environmental data, we will quantify the climate risk for vulnerable population groups and the health insurance sector in two different urban contexts (Berlin center and Potsdam) representing 2 typical European cities considering the period between 2005-2015. The focus in our showcase is on (urban) heat stress and air pollution affecting people with cardiopulmonary diseases, one of the most relevant impact pathways. In a second step, we will demonstrate how specific counteracting measures (establish ideal room temperatures, telemedicine to monitor the domestic environment, etc.) can help to reduce the impacts for vulnerable population groups and thereby to alleviate the costs, improve prevention, increase resilience and shorten recovery time.

### **P03.3620. Addressing Traffic Related Air Pollution: Local Public Health Challenges**

Emily Peterson

*1. Vancouver Coastal Health , VANCOUVER, BC, Canada.*

Abstract: The growing body of evidence on the health impacts of traffic related air pollution (TRAP) exposures and the widespread population exposures to TRAP have clear implications for local public health practitioners. Vancouver Coastal Health (Vancouver, BC) has been exploring ways to reduce population exposures to TRAP within the major municipalities in its jurisdiction. This includes exploring the feasibility of setbacks for buildings that house vulnerable populations (daycares, long-term care, hospitals, and schools), and promoting the health impact assessment process to address TRAP and other transportation related health impacts. Throughout this exploratory work many hurdles have been encountered from defining "high" TRAP exposure areas for building setbacks to challenges with weighing the pros and cons of daycare siting. Our ongoing exploration of and approach to this complex challenge will be discussed. The Health Protection team within Vancouver Coastal Health includes both Environmental Health and Community Care Facilities Licensing (child care, long-term care). Within Environmental Health the Healthy Built Environment team works in collaboration with local governments to create environments that promote and protect health.

### **P03.3630. Regional Priorization of Contaminants of Interest in Environmental Health Based on Human Biomonitoring Data**

Michelle Gagné

*Michelle Gagné<sup>1</sup>, Mathieu Valcke<sup>1</sup>, Fabien Gagnon<sup>1</sup>*

*1. Direction de la santé environnementale et de la toxicologie, Institut national de santé publique du Québec, Montreal, QC, Canada.*

**Abstract:** BACKGROUND/AIM: Limited financial and human resources command to establish priorities in terms of environmental contaminants of public health interest. The objective of this work was to establish a regional list of priority chemicals based on the interpretation of a relevant subset of Canadian Human biomonitoring (HBM) data. METHODS: HBM data for Quebec's participants were extracted from the Canadian Health Measures Survey for 50 environmental pollutants. The priority determination was first made by comparing the geometric mean and 95th percentile biomarker concentrations of these data with the baseline levels of the Canadian population. Quebec's HBM data were then compared to Biomonitoring Equivalent, which are screening tools developed in a health risk assessment context. Using this second approach, chemical-specific hazard quotients (HQs) or cancer risk levels were generated for about ten compounds. RESULTS: The comparison between Quebec and Canadian HBM data allowed to identify 3 chemicals for which Quebec inhabitants biomarkers concentrations are deemed significantly greater than for Canadians in general, based on the non-overlapping of the 95% confidence intervals of the geometric mean. Using the second approach, the level of priority was determined as medium or high for 7 compounds (HQ values >0.1 or cancer risk of >10<sup>-6</sup>). Due to the limited number of compounds for which Quebec HBM data are currently available, the results of recent prioritization exercises based on Canadian and US HBM data and using BE complemented the present analysis. Overall, 24 substances of interest were identified in the present work. Cadmium, prioritized under the two approaches mentioned above, as well as arsenic, lead and acrylamide figure among those. CONCLUSION: The list of priority chemical built here can contribute to orientate public health actions in order to reduce population's exposure to critical environmental contaminants, or contribute to identify relevant research themes.

### **P03.3640. Multidisciplinary Approaches for the Assessment of Human Exposure to Organic Pollutants in the Indoor Environment**

Tunga Salthammer

- 4. Rutgers University, Piscataway, NJ, United States.*

Abstract: Over time it became clear that exposure to chemical substances is complex in nature. We have come to understand that chemicals are distributed between the gas phase, airborne particles, settled dust and exposed surfaces, in a manner dependent on their respective physical properties. In terms of deposition and its effect, whether a molecule enters the lung via the gas phase or the particle phase makes a significant difference. The oral intake of substances from house dust is strongly dependent on the occupant's age and habit. The importance of the dermal intake pathway via the room air is now known and is the subject of several studies. Furthermore, we have also learned that secondary products from chemical reactions in the gas phase and on surfaces also contribute to exposure. Today, biomonitoring methods are available for many of the substances, which can be found in indoors. The identification of priority chemicals and the development of methods for these, with help from expert groups, is undoubtedly also a purposeful and seminal approach. With this contribution, which bases on a recent review paper, the authors hope to demonstrate that research addressing the sources, redistribution and fate of chemicals found indoors and human biomonitoring not only complement one another but also belong together within the field of exposure analysis. With the appropriate experimental design, external and internal exposure as well as the intake and uptake of a substance can be determined. A further important aspect is the post hoc analysis of house dust and urine samples, which are stored in environmental specimen banks. The identification and temporal tracking of so-called emerging chemicals is thereby enabled. This, in turn, creates the possibility of taking a virtual look into the future and acting preemptively, instead of constantly just looking back into the past and watching the decay of substances which have not been utilized for a considerable length of time.

### **P03.3650. Science and Policy of Fluorinated Surfactants in Firefighting Foam**

Tom Bruton

*Tom Bruton<sup>1</sup>, Arlene Blum<sup>1</sup>*

*1. Green Science Policy Institute, Berkeley, CA, United States.*

**Abstract:** The use of aqueous film-forming foam (AFFF) in firefighting activities has resulted in the release of poly- and perfluoroalkyl substances (PFAS) to soil and groundwater in numerous locations, affecting the drinking water of millions in the U.S. Regulatory attention has focused on the subclass of PFAS known as long-chain perfluoroalkyl acids, including perfluorooctane sulfonic acid (PFOS) and perfluorooctanoic acid (PFOA), due to their ubiquitous detection in the environment and their demonstrated hazard. For instance, U.S. EPA negotiated the phase-out of PFOS and PFOA with major manufacturers and issued drinking water health advisories for both substances. As firefighting foams containing long-chain PFAS have been phased out in the U.S., they have been replaced by formulations containing short-chain PFAS, despite the similar chemical properties of the two groups and the availability of PFAS-free alternatives. The widespread adoption of foams containing short-chain PFAS rather than fluorine-free foams was driven by a number of factors, some of which are scientific, others of which reflect the interests or values of different stakeholders. This presentation will compare and contrast the chemical and toxicological properties of long-chain and short-chain fluorinated surfactants used in AFFF, as well as the newer non-fluorinated alternatives. The presentation will also examine the environmental and firefighting performance criteria that resulted in the adoption of short-chain PFAS-based foams in the U.S. The evolution of firefighting foam use in the United States will be compared with that in other countries. Understanding the full context in which chemicals policy decisions such as this one are made can help scientists and policymakers find more effective solutions.

### **P03.3660. How Did Flint MI Happen**

Ronnie Levin

*Ronnie Levin<sup>1</sup>*

*1. Environmental Health, Harvard School of Public Health, Boston, MA, United States.*

Abstract: EPA's regulations to control lead contamination of drinking water are the most complicated of any of its drinking water regulations, and include source water analysis, identifying high risk sampling locations, sampling protocols that differ from all other drinking water sampling protocols, 50 times more samples, a different sampling regimen, and then treatment techniques, public education and even lead pipe removal. Nonetheless, media coverage of blatant violations of the US lead in drinking water rule repeatedly splay across newspapers throughout the country. The circumstances in Flint MI were the worst, but EPA's institutional tolerance of the widespread violations laid the foundation for what happened there. The very complexity of the lead rule provided the incentives and excuses for the 'gaming' that water utilities and their state overseers have used to avoid complying with the rule. It will only be through strengthened oversight and even public participation in monitoring that Americans will be protected against unnecessary lead contamination of public drinking water.

**P03.3670. Ambient Polycyclic Aromatic Hydrocarbons (PAHs) and Human Health Risks in Windsor, Canada and Detroit, U.S.A.**

Xiaohong Xu

*Xiaohong Xu<sup>1</sup>, Lindsay Miller<sup>1</sup>, Lawrence D Lemke<sup>3</sup>, Amanda J. Wheeler<sup>2</sup>*

*1. Civil and Environmental Engineering, University of Windsor, Windsor, ON, Canada.*

*2. University of Tasmania, Hobart, TAS, Australia.*

*3. Central Michigan University, Mount Pleasant, MI, United States.*

Abstract: Polycyclic aromatic hydrocarbons (PAHs) are toxic air pollutants with known adverse human health effects including cancer. A multi-year, high spatial density sampling campaign was carried out in two international border cities, Windsor, Ontario, Canada, and Detroit, Michigan, USA. The objectives were to 1) investigate the concentration levels and spatial distributions, 2) estimate incremental lifetime cancer risk (LCR) attributable to inhalation exposure of ambient PAHs, and 3) identify species and sources that are the major contributors to health risks. Air quality samplers were deployed for two two-week periods at approximately 50 sites in 2008 and 2009. Significant variability in concentrations, spatial distributions, and risk were observed between the two cities and between the two years. For individual PAH species and total PAHs, the concentrations were generally higher in Detroit than in Windsor and higher in 2009 than in 2008. Analysis of inter-species concentration ratios indicated both pyrogenic and petrogenic sources. Higher LCR levels were observed in Detroit than in Windsor in both years and were higher in 2009 than in 2008. The majority of the sites (74% in 2008 and 89% in 2009) registered LCR values above the 1 in 10<sup>6</sup> level, which implies that residents in both cities have the potential to be exposed to PAH related cancer risk at a non-inconsequential level defined by USEPA. Phenanthrene and anthracene combined account for more than 70% of the identified risks. This study provides unique perspectives on the spatial variability of ambient PAH concentrations, sources, and related health risks across two industrialized, urban cities that span an international border.

### **P03.3680. Evaluation of Health Symptoms and Air Exposures in Multiple Communities near Oil and Gas Operations in Colorado**

Allie Bamber

*Allie Bamber<sup>1</sup>, Tami McMullin<sup>1</sup>, Daniel Bon<sup>1</sup>, Mike VanDyke<sup>1</sup>*

*1. Colorado Department of Public Health and Environment, Denver, CO, United States.*

Abstract: Unconventional oil and gas (OG) activity in Colorado is increasing in areas with large population growth. Community scale exposures to substances emitted from OG operations is a public health concern. The Colorado Department of Public Health and Environment (CDPHE) has received over 200 citizen reports of acute health symptoms and odors during the development phases of drilling, fracking, and flowback by people living near OG sites. In response to reports of citizen health symptoms, we have completed six community exposure investigations, resulting in over 800 hours of air samples for 64 OG related volatile organic compounds (VOCs) and select criteria air pollutants collected during different phases of OG operations. Investigations included 15 grab samples collected by either citizens or staff, downwind of the OG site during times of reported symptoms/odors in attempt to quantify maximum exposures. To capture continuous air measurements of VOCs and meteorological conditions over a longer time during different phases of operations, we deployed our mobile laboratory four times to two different communities. For each exposure investigation, we conducted screening level health risk evaluations to assess the potential for acute and chronic non-cancer and cancer health effects to occur to in those communities. For all community samples, all individual and combined VOCs had hazard quotients below 1 for non-cancer health effects and were within EPA's acceptable excess cancer risk range. Based on our evaluation of the continuous air monitoring, there is no clear evidence that airborne VOCs from OG operations result in potentially harmful long-term exposures to those living nearby. Although limited, our analysis of grab samples also suggests a low risk of harm from short-term acute exposures. More extensive site specific community level air monitoring is needed to fully understand the relationship between reported health symptoms and OG air exposures in Colorado.

### **P03.3690. Collective Intelligence and Skills Mobilization: The Key of the Outbreak in Trois-Rivières**

Caroline Marcoux-Huard

*Caroline Marcoux-Huard<sup>1</sup>, Ann St-Jacques<sup>1</sup>*

*1. Department of public health of the CIUSSS MCQ, Centre intégré universitaire de la Mauricie et du Centre-du-Québec (CIUSSS MCQ), Trois-Rivières, QC, Canada.*

Abstract: In July 2017, 7 cases of Legionnaires' Disease (LD) were declared to the Public Health Department. This was unusually high considering the region has an annual average of 5 declarations of LD. Also, address of residence of cases indicated they lived in a 7 km radius from each other. This spacio-temporal aggregate prompted an outbreak investigation. The infectious disease team questioned patients and family. Questionnaire revealed that all of them spent time outside, in Trois-Rivières (TR), Québec, Canada. As well, a few patients had everyday activities that were almost exclusively in the downtown area. At the beginning of the investigation, the environmental health team rapidly validated cooling tower's (CT) microbiological water quality. They were under the intervention threshold prescribed by the provincial regulations. Concomitantly, other potential sources of a Legionella were investigated in regards to their outbreak potential. The epidemiological survey highlighted the information on the temporal distribution of this outbreak (critical period between July 4th and 17th) and the concentration of patient's displacements in the city center of TR, confirming spatial distribution, which made it possible to refine environmental investigation. Therefore, culture results of a CT in this area were scrutinized in detail and irregularities were found. This CT had the results of recurrent interfering flora. Thus, the CT was resampled and results showed contamination at 630 000 CFU/l (under the current health standard of 1 000 000 CFU/l). Subsequently, the CT was closed. Ultimately, the Legionella strain found in respiratory specimen of the patients was a genotypic match to the one cultured from the CT and had never been documented in Quebec before. Major surveys require the participation of multiple skills from different horizons and use collective intelligence. This outbreak illustrates the complementary of the epidemiological and environmental investigations.

### **P03.3700. Incorporating Lifecycle Emission Information in Promoting Chemical Exposure Screening**

Li Li

*Li Li<sup>1</sup>, Jon Arnot<sup>2</sup>, Frank Wania<sup>1</sup>*

*1. Physical and Environmental Sciences, University of Toronto Scarborough, Toronto, ON, Canada.*

*2. Arnot Research & Consulting, Toronto, ON, Canada.*

Abstract: While high-throughput human chemical exposure screening often relies on hazard indicators such as persistence and bioaccumulation potential, realistic human chemical exposure and potential health risks are also dependent on factors such as chemical use information and chemical-specific exposure pathways. Multimedia, multi-pathway exposure models are being used for chemical prioritization and screening, the parameterization of which requires chemical specific use and emission information (e.g., how is it emitted? how much?). This information, however, is often insufficient or missing for most chemicals in commerce. To address this issue, we propose integrating substance flow analysis, which is a powerful tool to derive chemical emissions throughout the chemical/product lifecycle, into high-throughput screening for human exposure potential. As an illustrative example, we combine a substance flow model (a simplified version of CiP-CAFE) with chemical fate and exposure models (RAIDAR and RAIDAR-ICE), to create a modeling continuum from the quantity produced or imported to human aggregate exposure. Our model requires inputs of basic properties of chemicals (e.g., partitioning coefficients, and degradation/biotransformation rates) and associated products (e.g., use categories, lifespans and material characteristics). These properties can either be retrieved from existing data resources or calculated by models, which enables the model's wide applicability to high-throughput screening of both existing and new substances. The model allows "forward" evaluation of human aggregate exposure to chemicals arising from their actual use, or "back" calculation of the critical production/import quantities of a chemical that would not cause an unacceptable level of risk (the latter depends on the availability of toxicological data). Overall, the approach demonstrates promise in high-throughput exposure screening of the myriad of chemicals.

**P03.3720. Genetic Polymorphisms Are Associated with Body Burden of Metals, Persistent Organic Pollutants (POPs) and Omega-3 Fatty Acid Levels among Inuit of Nunavik Region in the Canadian Arctic**

Rajendra Parajuli

*Rajendra P. Parajuli<sup>1</sup>, Jaclyn M. Goodrich<sup>2</sup>, Laurie Chan<sup>1</sup>, Melanie Lemire<sup>3</sup>, Pierre Ayotte<sup>3</sup>, Robert A. Hegele<sup>4</sup>, Nil Basu<sup>5</sup>*

*1. Department of Biology, Ottawa University, Sandy Hill, ON, Canada.*

*3. Département de médecine sociale et préventive, , Faculté de Médecine, Université Laval, Laval, QC, Canada.*

*4. Blackburn Cardiovascular Genetics Laboratory, Robarts Research Institute, London, ON, Canada.*

*5. Basu Laboratory, CINE Building, Macdonald Campus, Faculty of Agricultural and Environmental Sciences, , McGill University, Montreal, QC, Canada.*

Abstract: Mercury (Hg), cadmium (Cd), lead (Pb), dichlorodiphenyldichloroethylene (DDE), and polychlorinated biphenyls (PCB-153) are potent toxicants of concern to the general public, and are in high concentration in some Arctic country foods. On the other hand, polyunsaturated omega-3 fatty acids [docosahexaenoic acid (DHA) and eicosapentaenoic acid (EPA)] and selenium (Se) are vital nutrients found in marine diet. We hypothesize that single nucleotide polymorphisms (SNPs) in genes that mediate metabolism of toxicants and nutrients underline inter-individual differences in biomarker concentrations among a population living off local foods from aquatic and terrestrial ecosystems. Inuit members (n=665) from Nunavik (Quebec, Canada) were recruited in 2004 as part of the Qanuippitaa Survey. Blood samples were collected for quantifying toxicant (Hg, Cd, Pb, Se, DDE, PCB-153) and fatty acid (DHA, EPA) levels and genotyping (140 SNPs in genes relevant to toxicant or nutrient metabolism). Demographics were obtained from questionnaires. Here, we report results for 663 participants with complete genotype and biomarker datasets. ANOVA was used for statistical analysis. Mean (geometric) Hg, Cd, Se, Pb, DDE, PCB-153, DHA and EPA levels in blood were 11.07, 2.82, 301.2, 39.94, 2.92, 1.10 µg/L, 5.13 % / total fatty acid (TFA), and 1.31 % /TFA respectively. Out of 106 SNPs successfully genotyped, biomarker levels for Hg, Cd, Pb, Se, DDE, PCB-153, DHA, and EPA differed by genotype for 20, 11, 14, 1, 18, 23, 10 and 9 SNPs, respectively (ANOVA p<0.05). Only 13 SNPs (6 associated with Hg, 2 with Pb, 2 with DDE, 7 with PCB-153, 1 with DHA) remained significant following Bonferroni correction. The findings suggest that polymorphisms in environmentally-responsive genes can influence toxicants as well as nutrient biomarker levels. Hence, consideration of such gene-environment factors may improve the ability to assess the health risks and benefits of Arctic food more precisely.

**P03.3740. Key Exposure Models and Input Parameters Used for Assessing Exposure to Consumer Products Under Canada's Chemicals Management Plan**

Leona MacKinnon

*Ching-Yi (Jenny) Chen<sup>1</sup>, Leona MacKinnon<sup>1</sup>*

*1. Health Canada, Ottawa, ON, Canada.*

Abstract: Exposure models and associated input parameters are frequently used to estimate human exposure to chemicals in products available to consumers. The generation of intake estimates based on these models is often critical to assessing risks as mandated under Canada's Chemicals Management Plan (CMP). This poster presentation will highlight the impacts and challenges associated with using various exposure models based on the analysis of several published assessments conducted over the last decade. This includes a discussion on the rationale for the use of the models, and our tiered approach for refinements to exposure scenarios. The effects on the exposure estimates from modifying key parameters (e.g. mass transfer rate, product amount, and room volume) will be explored along with the presentation of case studies. Key similarities and differences between various consumer exposure models, including RIVM's ConsExpo, US EPA's Consumer Exposure Model (CEM), and Residential SOPs will be highlighted. This poster presentation showcases the decision making process when considering the models to use for characterizing exposure in assessments conducted under the CMP and exploratory work on new tools that can be used in future risk assessments.

### **P03.3750. Validation of the EAU Pharmaceuticals Workbook: Predicted Vs. Measured Environmental Concentrations**

Alison McLaughlin

*Norman Shek<sup>2</sup>, Dianne Hughes<sup>1</sup>, Alison McLaughlin<sup>1</sup>, Binjun Zhao<sup>1</sup>*

- 1. NSACB, HECS, Health Canada, Ottawa, ON, Canada.*
- 2. McMaster University, Hamilton, ON, Canada.*

Abstract: The EAU pharmaceutical workbook can be used to calculate environmental concentrations of pharmaceutical ingredients. Two model scenarios are considered, one for consumer use and another for manufacture. For 48 pharmaceutical substances, the average predicted environmental concentration (PEC) from the model was compared to average measured environmental concentrations (MEC) in wastewater effluents. A difference ratio with a value of less than |10| represents a PEC within 1 magnitude of the MEC, while a difference ratio with a value of less than |100| represents a PEC within 2 magnitudes of the MEC. Results showed that 54.2 - 62.5% of predictions are within 1 magnitude of measured environmental concentrations, and 89.6 - 93.8% of predictions are within 2 magnitudes of measured environmental concentrations. The consumer scenario gave PEC values closer to the MECs than the manufacture scenario.

### **P03.3760. Evaluation of Potential Health Risk of 6:2 Fluorotelomer Alcohol (FTOH)**

Hien Le

*Hien Q. Le<sup>1</sup>, Deborah R. Lander<sup>1</sup>, Shawn Gannon<sup>1</sup>, Christine M. Glatt<sup>1</sup>, William L. Buxton<sup>1</sup>, Robert C. Buck<sup>1</sup>*

*1. The Chemours Company, Wilmington, DE, United States.*

**Abstract:** Background Global fluorotelomer manufacturers have recently replaced the long-chain products with short-chain alternatives based on 6:2 fluorotelomer alcohol (FTOH) as a key raw material. FTOH is an intermediate used to manufacture polymeric water- and oil-repellent products, and its potential health risk has not been determined. Epidemiological studies regarding the human health effects of FTOH are not available. We conducted an exposure and risk assessment for FTOH. **Methods** Literature was reviewed and extracted for available FTOH environmental monitoring and toxicological data. Exposure assessment was conducted for inhalation, ingestion (dust and drinking water), and dermal routes of exposure in both general and occupational population. Exposures were estimated for different routes of exposures, applications, and populations using US Environmental Protection Agency Exposure Factors Handbook and CONSEXPO consumer product model. Human health risk assessment benchmarks were derived based on the available animal toxicity data and expressed as a risk characterization ratio (RCR). **Results** Inhalation and oral ingestion of dust are the most significant routes of exposure among adults (general and worker) and children, respectively. The RCRs based on conservative exposure estimates were <1 for all routes of exposures in both adults and children. An RCR <1 is an indication of no increase in health risk based on the derived human health risk assessment benchmarks of FTOH. **Discussion** While there is considerable published FTOH monitoring data, there has been no evaluation of health risk even though there is sufficient published animal toxicity data to do so. In order to evaluate risk, a comparison of exposure to hazard is required. This is an important part of evaluating health risk and prioritizing actions. Based on the conservative exposure assessments used in this evaluation, the current reported exposure levels of FTOH do not indicate an increase in human health risk.

**P03.3780. Ecohealth and Medical Geology Approaches as Integrative Methodological Tools to Address Environmental Lead or Arsenic Exposures and Health Issues in Uruguay**

Nelly Mañay

*Nelly Mañay<sup>1</sup>, Adriana Cousillas<sup>1</sup>*

*1. Toxicology - Faculty of Chemistry - Facultad de Química, University of the Republic of Uruguay (UDELAR), Montevideo, Uruguay.*

Abstract: Environmental public health issues have many interactions between social and environmental determinants so there is a need to combine exposure and health assessments. Then, contributions and knowledge integration of academics and stakeholders, focusing on transdisciplinary local and regional actions with a global perspective are required to address these new challenges. Ecohealth and Medical Geology approaches are invaluable methodological tools to apply in environmental health risks evaluations and to take transdisciplinary actions for communities health quality improvement on a regional and global scale. This work aims a retrospective outlook and experience gained of how these methodological approaches were applied in Uruguay to health issues studies and policies, due to urban lead contamination and arsenic levels in groundwater. Ecohealth approach has been very useful for lead contamination studies and population awareness as environmental management, health care, economic factors and demands or complains from the community were considered, of equal importance. Medical Geology has given a methodological framework of an interdisciplinary scientific field that integrates geosciences, and health sciences. Baseline studies on arsenic levels in groundwater and associated health risks are being developed with this approach, to improve public health prevention. The experience of applying these methodological approaches in Uruguay, has resulted in developing locally integrated research tools to understand how to link chemical environmental exposure and health impacts assessment, with the participation of the affected community, stakeholders and policy makers. In conclusion, Medical Geology and Ecohealth approaches are related and can improve understanding health impacts from geoenvironmental factors and ecosystems, integrating multidisciplinary knowledge and transdisciplinary thinking to give solutions of what can be done to minimize or prevent environmental health risks

### **P03.3790. Standard Rodent Housing Conditions Produce Significant and Sustained Levels of Particulate Matter**

Ben Nephew

*John Durant<sup>2</sup>, Alexandra Nemeth<sup>1</sup>, Neelakshi Hudda<sup>2</sup>, Doug Brugge<sup>3</sup>, Phyllis Mann<sup>1</sup>, Ben Nephew<sup>1</sup>*

*1. Biomedical Sciences, Tufts University Cummings School of Veterinary Medicine, North Grafton, MA, United States.*

*2. Department of Civil and Environmental Engineering, Tufts University School of Engineering, Somerville, MA, United States.*

*3. Public Health and Community Medicine, Tufts University School of Medicine, Boston, MA, United States.*

Abstract: While the mass of airborne particulate matter have established health guidelines for humans, similar recommendations are not available for laboratory rodent cages. Several studies have assessed the airborne contaminants produced by laboratory animals at the macroenvironment room level to reduce occupational health hazards for those working in animal facilities. These studies have led to established guidelines for protocols such as frequency of cage changes, animal room ventilation rates, and frequency of animal room air changes. However, microenvironmental cage measurements can differ greatly from the macroenvironmental room measurements. Cage-level particulate matter studies are needed to ensure that the laboratory rodent microenvironment is not having a detrimental effect on animal welfare and validity and relevance of scientific data. The objective of the current study was to assess PM levels produced by common rodent bedding types in bar lid and filter top covered rat cages. PM levels were assessed following artificial manipulation of the bedding (designed to simulate typical rodent activity) and during an hour of activity by two adult rats following a standard cage change using pine, aspen, paper, and corn cob bedding. Simulated activity and rat induced disruption of all types of bedding produced significant and substantial increases in PM (1000-6000  $\mu\text{g}/\text{m}^3$  PM<sub>2.5</sub>), with elevated levels ( $>50\mu\text{g}/\text{m}^3$ ) sustained for longer durations in cages with filter tops (5-6 minutes) compared to cages with only bar lids (0-2 minutes). These results indicate that standard laboratory housing conditions produce differentially substantial levels of PM that are likely to impact animal welfare and/or experimental data in animal studies of PM exposure.

**P03.3800. Nutritional Interventions for Childhood Lead Exposure: The Need for More Consistent Public Health Messaging across the International Community**

Danielle Ramos

*Danielle Ramos<sup>1</sup>*

*1. Office of Children's Health Protection, ASPPH/EPA, Washington, DC, United States.*

Abstract: Childhood blood lead levels (BLLs) have been decreasing over the last few decades due to various policies countries have adopted that were helpful in reducing sources of exposure and by providing appropriate public health messaging surrounding the science. Despite this decrease in BLLs, many children across the globe are still exposed to a variety of lead sources including those from paint, battery recycling facilities and mining activities, and have associated health impacts. Public health messaging surrounding appropriate nutritional interventions for children exposed to lead are misleading for parents and caregivers, and should be enhanced to provide the public with more consistent messaging surrounding up-to-date science. An assessment of the literature using PubMed was conducted to examine the availability of international epidemiological studies on the association between children with elevated BLLs and nutrient intake. Furthermore, a review of nutritional interventions by various health agencies was examined to understand specific language provided to parents for children with elevated BLLs. Unfortunately, messaging regarding nutritional interventions and childhood lead exposure is not always backed by the most current scientific data. Additionally, outreach materials are either nonexistent or varied across the international community, creating very inconsistent messages for parents and caregivers. While some data exists to support a connection between good nutrition and mitigation of lead absorption, there is lack of evidence that supports a connection between nutrient consumption and removal of lead in the body, which should be clearly distinguished in outreach materials. To ensure appropriate delivery of accurate messaging surrounding nutritional interventions for childhood lead exposure across the globe, an international effort to improve messaging surrounding appropriate nutritional interventions for children exposed to lead should be considered.

### **P03.3810. PFAS in the Drinking Water: A Swedish Register Study of Thyroid Disease**

Eva Andersson

*Eva Andersson<sup>1</sup>, Tony Fletcher<sup>2</sup>, Kristin Scott<sup>3</sup>, Yiyi Xu<sup>3</sup>, Kristina Jakobsson<sup>1</sup>*

- 1. Gothenburg University, Goteborg, Sweden.*
- 2. London School of Hygiene and Tropical Medicine, London, United Kingdom.*
- 3. Lund University, Lund, Sweden.*

**Abstract:** Background In Ronneby, Sweden, the use of fire fighting foam at a military airfield has resulted in the leakage of perfluorinated substances (PFAS) into the drinking water for part of the population. A population sample from Ronneby had median serum levels of PFOS, PFHxS and PFOA of 176, 152 and 10 ng/ml respectively. Materials and methods All individuals who ever lived in Ronneby municipality during 1980-2013 were included in the cohort. Each household was supplied by water from one of two waterworks, one of which was contaminated. A time-varying exposure was assessed, and exposure was classified into "never", "early" (1985-1994), "mid" (1995-2004) and "late" (2005-2013). Information from i) the National Patient Registers (on disease diagnosis), ii) the cause-of-death register and iii) the Prescribed Drug Register was linked through the personal identity number. Diagnosed cases of hypo- or hyper-thyroidism were identified from 1985 and on, and the corresponding medications from 2006 and on. Time to first diagnosis or prescription was analysed using a Cox proportional hazards model (age on the time axis, separate baselines for the three time periods). Results Approximately one third of the cohort (33800 men, 30396 women) had been exposed. For hyper-thyroidism diagnoses, the hazard ratios (HR) showed no significant increase, either for men or women. For hypo-thyroidism diagnoses, the HR was elevated among men (HR=1.36,  $p<0.05$ ), but no increased HR was seen in the prescription data. For women there was no significantly increase risk, either for diagnosis or prescription. Conclusion the register study gives no strong evidence for an increased risk of hyper- or hypo-thyroidism for individuals living at addresses with PFAS contaminated water in Ronneby, Sweden.

**P03.3820. More Than a Technical Challenge: The Social Life of Cumulative Risk and Mixtures Toxicity Policy**

Devon Payne-Sturges

*Devon Payne-Sturges<sup>1</sup>, Helen Mittmann<sup>2</sup>, Thurka Sangaramoorthy<sup>2</sup>, Robert Sprinkle<sup>3</sup>*

*1. MIAEH, University of Maryland School of Public Health, College Park, MD, United States.*

*2. Anthropology, University of Maryland, College Park, MD, United States.*

*3. School of Public Policy, University of Maryland, College Park, MD, United States.*

Abstract: It is widely recognized that Americans are exposed daily to multiple chemical compounds in our air, food, water, and consumer products, and that many low income and racial and ethnic minority populations bear a disproportionate share of these exposures. Significant research investments have been made to develop methods to assess the combined effects of multiple chemical exposures, and literature on the cumulative health effects of joint exposure to chemical and social stressors is growing. However, little progress has been made to advance federal and state policy responses to scientific findings about cumulative impacts and risk. We are conducting two studies, leveraging contributions from multiple disciplines, to explore the challenges related to advancing policies to reduce cumulative human health risks and impact at the U.S. Environmental Protection Agency and in the state of Maryland. Through science policy archival research and content analysis, ethnographic research methods, and policy analysis, we examine the scientific, social, and political framings of cumulative impacts and risk, and how they are understood and acted upon by legislators, environmental and public health agencies, business leaders, advocates, and other key stakeholders. Preliminary findings indicate three themes that emerge as barriers to the advancement of cumulative risk governance, policy, and regulatory decision making: concepts and terminology ("cumulative impacts" vs "cumulative risk"), issues of social justice, and ownership and responsibility. Understanding and overcoming these barriers are critical in order for decision makers to effectively address cumulative risks and impact of multiple chemical and social stressors

### **P03.3840. Data Evaluation Criteria for Exposure Studies**

Nathan Mottl

*Nathan N. Mottl<sup>1</sup>, Karie Riley<sup>2</sup>, Charles Bevington<sup>1</sup>, Nerija Orentas<sup>1</sup>, Eva Wong<sup>1</sup>, Francesca M. Branch<sup>1</sup>, Iris Camacho<sup>1</sup>, Cathy Fehrenbacher<sup>1</sup>*

- 2. Versar, Inc, Springfield, VA, United States.*

Abstract: On June 22, 2016, the Frank R. Lautenberg Chemical Safety for the 21st Century Act was signed into law thereby amending the Toxic Substance Control Act (TSCA), the Nation's primary chemicals management law. The amended TSCA requires EPA to make science decisions that are consistent with the best available science and the weight of the scientific evidence. The science standards must be implemented in both the hazard and exposure assessments of the TSCA risk evaluation to ensure that the underlying science is reliable and unbiased. To meet the standards, EPA developed criteria to assess the quality of multiple data types (i.e., monitoring data, modeling data, survey-based, epidemiology, experimental, database, etc.) supporting the exposure assessment. The criteria will be applied to the relevant data sources that were identified through a systematic search and met the inclusion criteria during screening and evaluation. Evaluation criteria are intended to assess the reliability, representativeness, accessibility/clarity, variability, and uncertainty of the data. This presentation will primarily focus on describing the evaluation strategy, including criteria, that EPA developed to assess the quality of the different types of exposure data. EPA is developing the data evaluation process during the analysis phase of risk evaluation. It will also identify potential issues encountered during the process as part of designing and executing systematic review approaches and methods to meet TSCA science standards. The views expressed in this abstract are those of the authors and do not represent Agency policy or endorsement.

### **P03.3850. General Factors of the Korean Child-Specific Exposure Factors**

Wonho Yang

*Wonho Yang<sup>2</sup>, Hyojung Yoon<sup>1</sup>, Jungkwan Seo<sup>1</sup>, Hyeon-Su Ryu<sup>2</sup>, Jinhyeon Park<sup>2</sup>, Sunshin Kim<sup>2</sup>*

*1. Department of Risk Assessment, National Institute of Environmental Research, Incheon, Korea (the Republic of).*

*2. Department of Occupational Health, Daegu Catholic University, Kyungsan, Kyungbuk, Korea (the Republic of).*

**Abstract:** Background/Aim Exposures among children are expected to be different from exposures among adults, because of physiological and behavioural differences. Children may be more exposed to some environmental agents because they consume more of certain foods and water per unit of body weight and have a higher ratio of body surface area to volume than adults. The purpose of this study was to produce the general factors of Korean child-specific exposure factors. Methods The general factors including body weight, body surface area, inhalation rate, intake of drinking water and food, and time-activity pattern of Korean children aged 0 to 18 years were investigated. The produced recommended values of general factors were compared with other countries. Results Long-term inhalation rates in male and female were 13.64 m<sup>3</sup>/day and 11.78 m<sup>3</sup>/day, respectively. And short-term inhalation rates of resting, slow walking (light exercise), and slow running in male were 0.55 m<sup>3</sup>/hr, 1.084 m<sup>3</sup>/hr, and 1.368 m<sup>3</sup>/hr, respectively. 93.02% (18.44 h) for a day was spent in indoors on average, considering weekday and weekend day together. The most time (18.44 h, 76.83%) was spent in residential indoor. The times spent in schools or kindergartens (nurseries) and other indoors were 2.66 h (11.09%) and 1.21 h (5.09%), respectively. The time spent in outdoors and transports was 0.81 h (3.36%) and 0.87 h (3.61%), respectively. Hand-to-mouth and object-to-mouth frequencies (contact/hr) aged 1 to 6 years were 4.80 contacts/hr and 3.26 contacts/hr, respectively. Conclusions This study was carried out for the first time in Korea. Risk assessment considers the situations and characteristics of the exposure environment and host. Various physiological variables of the human body reflects the characteristics of the children that can directly influence risk exposure. Therefore, identification of exposure factors based on the Korean children is required for appropriate risk assessment.

### **P03.3860. Regulating Chemical Exposures: Using Legal Epidemiology to Determine Enforceable PFAS Standards**

Jennifer Black

*Jennifer Black*<sup>1</sup>

*1. Public Health law Program, Cherokee Nation Assurance, contractor for the Centers for Disease Control and Prevention, Atlanta, GA, United States.*

Abstract: PFAS is a large family of man-made chemicals present in stain-resistant, waterproof, and non-stick consumer products. PFAS accumulates in biological tissues and does not break down when exposed to natural elements like air, wind, or water. They can also travel long distances through the air, meaning that exposures can occur beyond where PFAS is manufactured. Exposure can lead to health concerns such as kidney and liver issues, immune disorders, and decreased response to vaccinations. Some of these chemicals are also known to spread to fetuses in cord blood and to newborns through breast milk. PFAS are currently not subject to the national primary drinking water regulations under the Safe Drinking Water Act. Instead, EPA develops Health Advisories (HAs) for them, which are not legally enforceable and only serve as technical guidance. Therefore, states must regulate these chemicals to have any enforcement ability. Researchers sought to identify states with legally-enforceable PFAS requirements and policies related to PFAS. Using legal epidemiology methods, legal researchers assessed PFAS laws and policies across the 50 states and DC. Researchers developed coding questions to account for the content of the laws, such as exposure limits in each state and which mediums were regulated (i.e. water, air, soil). This presentation will describe how state and local health and environmental departments can use this information to inform their own laws and prevent exposure to harmful chemicals.

### **P03.3870. Challenges in the Application of Systematic Review Methods for Environmental Hazard Identification: Lessons Learned and Future Considerations**

Suril Mehta

*Suril S. Mehta<sup>1</sup>, Whitney D. Arroyave<sup>2</sup>, Pamela J. Schwingl<sup>2</sup>, Ruth Lunn<sup>1</sup>*

*1. Office of the Report on Carcinogens, Division of the National Toxicology Program, National Institute of Environmental Health Sciences (NIEHS), Research Triangle Park, NC, United States.*

*2. Integrated Laboratory Systems (ILS), Morrisville, NC, United States.*

**Abstract:** Systematic review methods aim to increase transparency, rigor, and reproducibility of literature-based evaluations, for the purposes of reaching a weight-of-evidence conclusion. These methods are becoming a gold-standard for reaching hazard conclusions for environmental exposures. They also have broad policy implications, and are being used by governmental bodies in public health decision-making. However, many of these methods were created with the evaluation of clinical studies in mind. Key differences exist when applying systematic review methods intended for evaluating the effectiveness of a clinical intervention to environmental studies. Unlike clinical trials, environmental and occupational exposure studies have greater variability in their study designs, populations and exposures. Steps in the systematic review process - literature searching, publication selection, and study quality evaluations- are more complex, labor-intensive, and prone to human error. Significant manpower and scientific expertise is needed to produce a quality evaluation. We describe the application of systematic review process for evaluating observational studies in environmental health. For example, the U.S. Report on Carcinogens has applied these methods to six cancer hazard assessments (e.g., trichloroethylene, light at night/shift work). New and existing systematic review tools have been developed specifically for environmental health to aid in the process. An overview of tools for literature searching, systematic data extraction, risk of bias (i.e., study quality) and sensitivity evaluations, and meta-analyses will be discussed. We also offer considerations for the utility of these tools including the development of novel automation techniques in relation to the purpose and quality of a review. Lastly, we propose future steps to improve methods and utilize new techniques to improve causal inference.

### **P03.3880. Students' Environmental Risk Perception in University of Catania (South Italy): Results of a Cross-Sectional Study**

Maria Fiore

*Maria Fiore<sup>1</sup>, Alessandra Giarratana<sup>3</sup>, Agata Ferlito<sup>1</sup>, Gea Oliveri Conti<sup>1</sup>, Annalaura Carducci<sup>2</sup>, Margherita Ferrante<sup>1</sup>*

*1. Department "GF Ingrassia", University of Catania, Catania, Italy.*

*2. Health and Environment Work Group, Italian Hygiene Society (SITI), Catania, Italy.*

*3. Specialization School of Hygiene and Preventive Medicine, University of Catania, Catania, Italy.*

**Abstract:** Introduction: Risk perception is associated to different socio-cultural and individual factors, like subjective judgment and level of Health literacy (HL), which are poorly studied in Italy. This study has investigated students' environmental risk perception related to the level of HL. Methods: Enrolment was carried out in scientific-health and humanistic-legal-social sectors in the University of Catania. The students filled out a structured questionnaire in three sections that explore socio-demographic, environmental risk perception and HL data. The HL was calculated by assigning a score of 1 to each correct answer and calculating their mean. The mean values were divided into two categories: poor vs good ( $\leq 9$  vs  $> 9$ ). A risk perception score was calculated by summing up the item ratings. Collected data was stratified by HL. A logistic regression model was used to identify possible factors associated with a low environmental risk. Significance was set at  $p \leq 0.05$ . Results: We enrolled 574 students (365 females, 209 males), aged between 18 and 44, 320 of whom attending scientific-health sector and 254 humanistic-legal-social sector respectively. At the logistic regression analysis the students with a low environmental risk perception resulted to be affected by almost a threefold risk of getting away from high HL (OR = 2.96; CI 95% 1.16-7.54). HL was influenced by students' age ( $<21$  vs  $>22$ ; p-value= 0,000), the sectors (scientific-health vs humanistic-legal-social sectors) and duration of the study course (three vs six years; p-value 0,000). Conclusions: Our results highlight that focus on HL might improve students' environmental risk perception which may bring positive impact on making decisions, planning and implementing strategies.

### **P03.3920. Use of Twitter Data to Improve Zika Virus Surveillance in the United States during the 2016 Epidemic**

Jun Wu

*Shahir Masri<sup>1</sup>, Jianfeng Jia<sup>2</sup>, Chen Li<sup>2</sup>, Guofa Zhou<sup>1</sup>, Ming-Chieh Lee<sup>1</sup>, Guiyun Yan<sup>1</sup>, Jun Wu<sup>1</sup>*

*2. Department of Computer Science, University of California, Irvine, Irvine, CA, United States.*

Abstract: Zika virus (ZIKV) is an emerging mosquito-borne arbovirus that can produce serious public health consequences. In 2016, ZIKV caused an epidemic in many countries around the world, including the United States. ZIKV surveillance and vector control is essential to combating future epidemics. However, challenges relating to the timely publication of case reports significantly limit the effectiveness of current surveillance methods. In many countries with poor infrastructure, established systems for case reporting often do not exist. Previous studies investigating the H1N1 pandemic, general influenza and the recent Ebola outbreak have demonstrated that time- and geo-tagged Twitter data, which is immediately available, can be utilized to overcome these limitations. In this study, we employed a recently developed system called Cloudberry to filter a random sample of Twitter data to investigate the feasibility of using such data for ZIKV epidemic tracking on a national and state (Florida) level. Two auto-regressive models were calibrated using weekly ZIKV case counts and zika tweets in order to estimate weekly ZIKV cases one week in advance. A comparison of predicted versus observed weekly ZIKV case counts following model calibration demonstrated overall good predictive accuracy, with an R<sup>2</sup> of 0.74 for the Florida model and 0.70 for the U.S. model. Time-series analysis of predicted and observed ZIKV cases following internal cross-validation exhibited very similar patterns, demonstrating good model performance. Spatially, the distribution of cumulative ZIKV case counts (local- & travel-related) and zika tweets across all 50 U.S. states showed a high correlation ( $r = 0.73$ ) after adjusting for population. This study demonstrates the value of utilizing Twitter data for the purposes of disease surveillance, which is of high value to epidemiologist and public health officials charged with protecting the public during future outbreaks.

### **P03.3930. Green Spaces and Self-Satisfaction and Social Contacts in Adolescents: The Caspian-V Study**

Sanam Hariri

*Sanam Hariri<sup>1</sup>, Payam Dadvand<sup>2</sup>, Behzad Abbasi<sup>1</sup>, Ramin Heshmat<sup>4</sup>, Mostafa Qorbani<sup>5</sup>, Xavier Basagaña<sup>2</sup>, Roya Kelishadi<sup>3</sup>*

**Abstract:** Introduction: A growing body of evidence has associated contact with green spaces with improved mental health and wellbeing in adults. Few studies have also suggested social contact as a potential mechanism underlying health effects of green spaces. The aim of this study was to evaluate the association of the use of green spaces with self-satisfaction and social contact in adolescents. Towards this aim, it also disentangled the associations for different types of green spaces, evaluated the modification of these associations by socioeconomic status (SES), level of urbanity, and sex, and investigated the mediator role of social contact in the association between use of green spaces and self-satisfaction. Methods: Data were obtained through valid questionnaires from a population-representative sample of 10,856 adolescents (10 to 18 years old) living in urban and rural districts across Iran who participated in the fifth survey of a national school-based surveillance program (CASPIAN-V). Logistic mixed effects models with recruitment centre as the random effect were developed to estimate associations adjusted for relevant covariates. Results: More time spent in green spaces was associated with improved self-satisfaction and social contact. While for the self-satisfaction association, we did not observe any indication for effect modification by sex, SES, and urbanity, there were some suggestions for stronger associations for social contacts for boys and those residing in rural areas or from lower SES groups. Social contact could explain more than half of the association between green space use and self-satisfaction. Conclusions: Longer time spent in green spaces was associated with enhanced self-satisfaction and social contact. Social contact could possibly act as a mediator for the association between green space use and self-satisfaction. Further longitudinal studies are required to replicate our findings in other populations with different cultures and lifestyle habits.

### P03. Occupational Issues 3

#### **P03.3940. Lived Experiences of Heat Exposure as an Occupational Safety Hazard in Australia**

Alana Hansen

*Alana Hansen<sup>1</sup>, Dino L. Pisaniello<sup>1</sup>, Blesson M. Varghese<sup>1</sup>, Peng Bi<sup>1</sup>*

*1. School of Public Health, The University of Adelaide, Adelaide, SA, Australia.*

**Abstract:** Workers exposed to hot environmental conditions can be at heightened risk of heat-induced illnesses and injuries. With hot days becoming more frequent in Australia, heat exposure is gaining importance as a major health and safety issue for workplaces. The aim of this study was to use a qualitative approach to better understand how heat exposure can lead to occupational injury in order to inform prevention measures. Twenty one semi-structured interviews were conducted across five Australian states with people who had direct experience or knowledge of hot outdoor or indoor work environments. The participants, aged between 23 and 68 years, spoke about heat-associated hazards in industries including construction, mining, manufacturing, transport, emergency services and agriculture. Participants recounted occupational heat-related illnesses and injuries, ranging from minor to permanently disabling, and in some cases, fatal. Often there were confounding and contributing factors as well as heat strain which led to actual or potential adverse outcomes. Those affected included experienced, acclimatised and healthy workers in both indoor and outdoor environments. Migrant workers under visa conditions were identified as a particularly vulnerable subgroup in terms of both working conditions and predisposing living conditions. Recommendations from interviewees included more training and awareness for individuals, co-workers and supervisors. Overall, the participants' diverse narratives highlighted a range of heat exposures leading to compromised occupational health and safety, and the difficulties associated with formulating guidelines and effective preventive measures to suit all work situations.

### **P03.3950. Heat Exposure, Volume Status, and Kidney Tubular Injury in Washington Crop Workers**

June Spector

*June Spector<sup>1</sup>, Gabino Abarca<sup>1</sup>, Jennifer Krenz<sup>1</sup>*

*1. Environmental and Occupational Health Sciences, University of Washington, Seattle, WA, United States.*

**Abstract:** Objective: Acute kidney injury has been observed in US agricultural workers, and repeated dehydration in the setting of heavy physical work may contribute to the global problem of chronic kidney disease of unknown etiology (CKDu). We sought to assess the relationship between personal ambient heat exposure and biomarkers of early kidney injury in Washington (WA) tree fruit harvesters. Methods: Forty-five harvesters participated in a cross-sectional study during the summer of 2015. Heat exposure was assessed as the maximum work-shift wet bulb globe temperature (WBGT) measured near each participant, and kidney outcomes were assessed using urine tubular biomarkers ( $\beta$ 2 microglobulin, N-acetyl-B-D-glucosaminidase [NAG]). Pre/post-shift urine specific gravity (USG) was measured to assess volume status. Pre- and post-shift biomarkers were compared using paired Student's t-tests. Associations between maximum WBGT and post work-shift biomarkers were evaluated using mixed effects models, adjusted for relevant confounders. Results: Mean (sd) pre-shift USG (1.025 [0.007]) indicated mild dehydration. Workers whose USG changed from  $\geq 1.025$  pre-shift to  $< 1.025$  post-shift (n=8) exhibited a decrease in mean NAG normalized to USG (5.7 (1.2) to 3.9 (1.5) U/L;  $t[7]=5.24$ ,  $p=0.04$ ), but results were different for urine  $\beta$ 2 microglobulin outcomes, which can be affected by diurnal variation, and when normalizing biomarkers using urine creatinine. There was no significant relationship between maximum WBGT and post-shift urine  $\beta$ 2 microglobulin and NAG. Conclusion: Optimizing volume status both pre-shift and during the work-shift may help prevent adverse kidney effects in workers laboring in the heat. Selection and analysis of biomarkers of early tubular injury should include consideration of: 1) diurnal variation over the course of the day; 2) normalization approaches, as adjustment of biomarkers using urine creatinine may be problematic in populations performing physical exertion.

### **P03.3960. Prevalence and Risk Factors of Chronic Kidney Disease among Workers in the Brick Making Industry of La Paz Centro, Nicaragua**

Madeleine Scammell

**Abstract:** In Central America there is an epidemic of chronic kidney disease (CKD) of non-traditional etiology. Few studies have assessed CKD prevalence among non-agricultural workers. We conducted an observational study of 224 artisanal brick workers in La Paz Centro, Nicaragua. Prevalence was based on serum creatinine measures at two time points four months apart. Predictors examined include: Age, sex, education, smoking status, body mass index, alcohol consumption, water consumption, family history of CKD, years worked, hours worked, job category, and time (baseline vs. follow-up). Outcomes included serum creatinine-based estimated glomerular filtration rate (eGFR) and stage of CKD. Results indicate CKD prevalence of 14.3% based on the proportion of participants with eGFR < 60 ml/min/1.73m<sup>2</sup> at both time points; 97% of cases were male, 25% were less than 35 years of age, and 28% had stage 5 CKD (eGFR <15 ml/min/1.73m<sup>2</sup>.) Predictors identified by linear mixed effects models included a job task that entails loading or operating the oven, age, sex, education, smoking status, water intake, and family member with CKD. Limitations of this study include a crude job classification metric, loss to follow-up, small sample size, self-reported questionnaire data, and no quantification of albuminuria. According to NHANES 2011-2014 data, estimates of US prevalence ages 20-39 and 40-59 with eGFR <60 ml/min/1.73m<sup>2</sup> were 0.3% and 3.3% respectively, whereas the percentage of participants in the present study (aged 18-61) with eGFR < 60 ml/min/1.73m<sup>2</sup> at baseline and follow-up was 15.2% and 17.4%, respectively, suggesting that CKD prevalence is abnormally high in this predominantly young population. High prevalence of CKD including at advanced stages indicates that the epidemic of CKD is affecting non-agricultural workers in Nicaragua. These results support the hypothesis that occupational heat exposure and socioeconomic conditions are risk factors for decreased kidney function in this region.

### **P03.3970. Cancer Risk in Drivers of Heavy Vehicles: Assessment of Exposure to Petroleum Hydrocarbons, Toxic Effects and Prevention Interventions**

Audil Rashid

*Audil Rashid<sup>1</sup>, Atif Kamal<sup>1</sup>, Sumia Sahar<sup>1</sup>*

*1. EcoHealth Research Lab, Environmental Science, PMAS Arid Agriculture University, Rawalpindi, Pakistan.*

**Abstract:** Cancer development among occupational groups is unnoticed in resource limited settings. Poor drivers of heavy vehicles work for long hours to meet their family needs. As a result of diesel or fuel burning, they are directly exposed to mixture of petroleum hydrocarbons through inhalation, standby activity and skin contact. The purpose of this study is to identify effective methods of exposure prevention to petroleum hydrocarbon carcinogens and associated toxic effects among truck/bus-drivers by completing following specific aims: i) quantify exposure to carcinogens related to work shift; ii) identify urinary and serum biomarkers of carcinogen effect in relation to occupational exposure; and iii) epidemiological analysis of health outcomes to assess the exposure risk to carcinogens. Drivers of heavy vehicles in Rawalpindi were evaluated for exposure to dust, PM10, PM2.5 and polycyclic aromatic hydrocarbons (PAHs). Blood and urine samples were collected for post-shift activities followed by medical surveillance evaluations based on self-reported health outcomes. Initial exposure estimates revealed that with 9 hrs day<sup>-1</sup> or more driving hours have unprecedented exposure to PM10 followed by dust and PAHs. Serum benzo(a)pyrene (BaP), naphthalene and pyrene values (median ranges 9.35, 21.61 and 7.44 µg L<sup>-1</sup> respectively) appeared significantly correlated (coefficient r from 0.43 to 0.58; p<0.001) with exposure. Urinary PAH biomarker 1-hydroxy pyrene > 6.6 µg L<sup>-1</sup> had significantly high prevalence of physical disorders (OR=4.12; 95% CI=1.95-7.58), an indication of carcinogenic effect and indirect exposure to high PAH levels. Among truck drivers, cancer risk evaluation using Incremental Lifetime Cancer Risk Model (ILCR-model 2) suggested 61% had high exposure to petroleum hydrocarbon carcinogens. We conclude that serum pyrene and BaP are important biomarkers for PAH carcinogens.

### **P03.3980. Occupational Physical Activity and Lung Cancer Risk among Participants of the Alberta's Tomorrow Project**

Yun Zhu

*Yun Zhu<sup>1</sup>, Jerome Lavoue<sup>2</sup>, Marie-Elise Parent<sup>3</sup>, Jack Siemiatycki<sup>1</sup>, Anita Koushik<sup>1</sup>, Vikki Ho<sup>1</sup>*

*1. Health Innovation and Evaluation Hub, University of Montreal Hospital Research Centre, Montreal, QC, Canada.*

*2. Department of Occupational and Environmental Health, University of Montreal, Montreal, QC, Canada.*

*3. INRS-Institute Armand Frappier Research Centre, Laval, QC, Canada.*

**Abstract:** Purpose Empirical evidence of a possible association between occupational physical activity (PA) and lung cancer risk has been inconclusive. Previous studies have seldom considered occupational exposure to lung carcinogens, which are potentially major confounders that might distort the true effect. This study aimed to investigate the independent association of occupational PA with lung cancer risk, and to determine if this association varies by smoking status. Methods Among participants of the Alberta's Tomorrow Project, we identified 172 incident lung cancer cases and a random sample of 688 non-cases. Data on the longest-held occupation and lifestyle factors were gathered via questionnaires. Using a database generated by our team on the energy expenditures associated with almost 3600 job titles, we assigned metabolic equivalent of tasks to the longest-held job of each participant. Exposure to lung carcinogens in these same jobs was determined using the Canadian Job Exposure Matrix. In preliminary analyses, multivariable logistic regression models have been used to estimate odds ratios (ORs) and 95% confidence intervals (CIs) for the relation between occupational PA and lung cancer risk. Results Higher occupational PA level was associated with a reduced risk of lung cancer (highest versus the lowest tertile OR=0.50; 95%CI: 0.26-0.95), particularly for non-small cell tumor (OR=0.46; 95%CI: 0.24-0.90). The protective effect of occupational PA was similar among men and women. Additionally, we observed a potential interaction between occupational PA and smoking status, where a decreased risk of lung cancer associated with increasing PA was limited to never smokers (OR=0.27;95%CI: 0.10-0.71; Ptrend=0.008; Pinteraction=0.044). We did not observe evidence for modification of ORs by occupational lung carcinogen exposure. Conclusion Preliminary analysis is suggestive that occupational PA is inversely associated with the risk of lung cancer with a stronger effect in never smokers.

### **P03.3990. Follow-Up Mortality Study of U.S. Railroad Right of Way Workers Having Many Common Health Hazards**

David Goldsmith

*David F. Goldsmith<sup>1</sup>*

*1. Human Science, Georgetown University, Silver Spring, MD, United States.*

**Abstract:** Introduction: U.S. Right of Way (MOW) railroad (RR) workers have exposures to diesel and welding fumes, ballast (silica) and asbestos dust, creosote and solvents, and heavy equipment. We hypothesize that these workers have elevated risk for chronic pulmonary and kidney diseases (DIS), neurological ailments, as well as cancers (CA) of the lung, prostate, GI, and lymphatic CAs. Methods: Names of union RR workers were submitted to the U.S. National Death Index for the years 1979 to 2014. When a match was found, these persons were organized into ICD groups. We calculated standardized mortality ratios (SMRs) and 95% confidence intervals (CI) for 11,190 deceased males, aged 18 to 64. Results: Compared to U.S. males, these active-age MOW workers have an all cause SMR of 1.63. Parkinson's and Alzheimer's DIS show elevated SMRs of 3.09 and 7.15; heart DIS has SMR of 2.11; COPD has a SMR of 1.89 (95% CI 1.66, 2.13); kidney DIS has a SMR of 2.50 (95% CI 1.99, 3.01); and transportation accidental deaths have a SMR of 3.27. All CA showed an SMR of 1.79. Stomach, bladder, colo-rectal CAs and leukemia have an approximate risk of 2.0; liver CA has a SMR of 2.36 (95% CI 1.95, 2.78); pancreatic CA produced a SMR of 2.17 (95% CI 1.84, 2.50); lung CA has a SMR of 1.82 (95% CI 1.71, 1.94); prostate CA produced a SMR of 1.93 (95% CI 1.52, 2.34); and bladder CA has a SMR of 1.95 (95% CI 1.35, 2.55). Discussion: With an SMR of 3.27, the risk among RR workers from transport accidents is consistent with hazardous work around heavy rolling equipment. Elevated risks for kidney, heart, neurological DISs, and COPD are consistent with dust or fuel exposures from ballast and other hazards. Our findings suggest that the increased SMR for all neoplasms is likely based on elevated risks for CA of bladder, pancreas, prostate, liver, and lung. Conclusion: Elevated SMRs for many diseases among MOW workers suggests past risks that need to be addressed via additional studies and effective prevention programs.

### **P03.4000. Passive Samplers for the Assessment of Occupational Exposure to Flame Retardants among Canadian E-Waste Dismantlers**

Linh Nguyen

*Linh V. Nguyen<sup>1</sup>, Victoria Arrandale<sup>2</sup>, William A. Stubbings<sup>3</sup>, Jiehong Guo<sup>3</sup>, Marta Venier<sup>3</sup>, Lisa Melymuk<sup>4</sup>, Liisa Jantunen<sup>5</sup>, Miriam L. Diamond<sup>6</sup>*

- 5. Air Quality Processes Research Section, Environment and Climate Change Canada, Toronto, ON, Canada.*
- 6. Department of Earth Sciences, University of Toronto, Toronto, ON, Canada.*

**Abstract:** The mass of e-waste produced globally is growing dramatically. One hazard, especially for e-waste handlers, are flame retardants (FRs) which are added to electronic and electrical equipment in order to meet flammability standards. FR air concentrations can be measured using active air sampling equipment, but this sampling train can be cumbersome for workers. Passive samplers made from polydimethylsiloxane (PDMS) or silicone rubber, are one option for simplifying the measurement process. Here, we compared PDMS passive air samplers (PDMS-PASs) with active air samplers for the assessment of FR air levels at an e-waste dismantling facility in Ontario, Canada for the purpose of estimating occupational exposure. Sampling was conducted daily over a five days in February 2017. PDMS-PASs were hung at 4 workbenches and a central workplace, and were co-deployed with an active low-volume air sampler which consisted of a GFF followed by a PUF/XAD/PUF sandwich. Each PDMS and low-volume sampler was harvested after 24 hours. Samples were extracted and analysed for 13 FRs, including novel brominated flame retardants (NFRs), polybrominated diphenyl ethers (PBDEs) and organophosphate esters (OPEs), using gas chromatography mass spectrometry (GC-MS). The most abundant FRs were the now-banned PBDEs (BDE-209 accounted for ~70-98 % of FRs collected by PDMS-PASs). Total median concentrations of PBDEs in PDMS-PASs at the central workplace and workbenches were 1930 and 2900 ng/m<sup>3</sup>, respectively. PDMS-PASs provided comparable estimates of air concentrations to active samplers. The chemical profiles from the PDMS matched those from active sampling, indicating that differences in compound gas-particle partitioning did not affect the sampling efficiency of PDMS. Levels of FRs in air collected from this Canadian e-waste recycling facility suggest PDMS-PASs can be used to estimate occupational exposure to FRs, even for short deployment times at workplaces with elevated levels of these chemicals.

### **P03.4010. Occupational Exposures and Thyroid Disease Risk in Young Adults: Results from Project ELEFANT**

**Abstract:** Background: Thyroid disease is one of the leading endocrine disorders, with disruption of thyroid stimulating hormone (TSH) levels commonly implicated in disease aetiology. Aims: We sought to examine associations between occupational exposure to radiation, organic solvents and vibration in relation to TSH levels and risk of thyroid diseases. Methods: We utilized data from 124,286 participants within Project Environmental and Life Style Factors in Metabolic Health Through Life-course Trajectories (ELEFANT). Participants were aged between 18 and 40 and reside in Tianjin, China. Questionnaire data on lifestyle and occupational exposures was collected, and medical records reviewed to collect data on history of thyroid disease. TSH levels were measured by automated immunometric assay. Results: The participants were predominantly from the Han ethnic group (97.9%), lived in rural areas (63.7%), and worked as farmers (52.6%). The prevalence of thyroid disease was 0.4% (n=528). In logistic models adjusted for confounders (age, BMI, education, residence, occupation, smoking and co-exposures), exposure to radiation [odds ratio (OR): 1.73; 95% CI: 1.1-2.7], organic solvents [OR: 2.0; 95% CI: 1.3-2.9] and vibration [OR: 4.4; 95% CI: 2.0-8.75] were significantly associated with higher risk of thyroid disease. TSH levels, measured only in women (median: 1.95 mIU/L; 95% CI: 2.45-2.77 mIU/L), were observed to be associated only with vibration exposure ( $\beta$  (95% CI): 2.80 (1.07-4.54) mIU/L;  $p=0.0016$ ). Conclusions: Our data demonstrate for the first time that vibration exposure is associated with significantly increased TSH levels and increased risk of thyroid disease. Further work is required to establish the mechanisms underlying this association.

### **P03.4030. Exposure to Metal Fume Particulate Matter and Advance Glycation End Products in Welding Workers: A Longitudinal Study**

**Abstract:** Previous studies have demonstrated the association of exposure to air pollution and the diabetes mellitus (DM). Insulin resistance has been regarded as an underlying mechanism of type 2 DM. Studies have shown transition metal ions play important roles in the Maillard reaction. The objective of this study was to assess the effects of metal fume particulate matter and nickel (Ni) on insulin resistance among the welders and to understand its association with advanced glycation end products (AGEs) formation. This study was in a longitudinal design. Study subjects consisted of 74 welders and 28 office workers from a shipyard of northern Taiwan at baseline Oct, 2014 and followed up annually on Oct to Nov, 2015 and 2016. Participants were asked to wear a PM2.5 sampler during their working hours on the first weekday (Monday) and collected urine and fasting blood samples on the next day (Tuesday) morning. A total of 233 measurements were collected and included in the subsequent statistical analyses. Urinary Ni was assayed as biomarkers of internal dose of nickel exposure. Plasma adiponectin and AGEs were measured as biomarkers of cardiovascular effects. Urinary 1-hydroxypyrene (1-OHP) was used as a biomarker of exposure to polycyclic aromatic hydrocarbons (PAHs). Personal PM2.5 exposure levels were significantly associated with urinary 1-OHP concentrations according to the generalized estimating equation (GEE) analysis after adjusting for confounds. Log(Ni) was negatively associated with log(Insulin)( $\beta = -0.056$ , 95% CI -0.110 to -0.001,  $p < 0.05$ ). Log(Ni) was positively associated with log(adiponectin)( $\beta = 0.160$ , 95% CI 0.080 to 0.238,  $p < 0.001$ ). Log(Ni) was positively associated with log(AGEs)( $\beta = 0.119$ , 95% CI 0.041 to 0.197,  $p < 0.01$ ). Urinary Ni levels are associated decreasing insulin levels. Urinary Ni levels are positively associated with formation of AGE. Exposure to metal fume particulate matter may increase advance glycation end products in welding workers.

### **P03.4040. Exposure Neuroepidemiology Study among Occupational Groups with High Exposure to Aviation Emissions**

Faiza Naseem

*Luqman Riaz<sup>1</sup>, Audil Rashid<sup>1</sup>, Ikhtiar Uddin<sup>1</sup>, Faiza Naseem<sup>2</sup>*

**Abstract:** Aviation industry personnel working at the airports in Pakistan are confronted with neurasthenic and physical problems mainly because of unprecedented exposure to jet fuels and also there is no proper health monitoring services are extended to them. We aimed to assess dermal exposure of workforce at airports to jet propellant (JP) fuel (e.g. JP4, JP5, and JP8) which contains a complex of mixture of Polycyclic Aromatic Hydrocarbons (PAHs). To document the extent of acute toxic exposure levels, protective strategies, working hours and job nature were used as predictors. Among aviation workforce members, who work for more than six hours per day, we took both skin pad and urine samples to measure dermal exposure by PAH and subsequent secretion through body. To detect biological marker for dermal exposure urinary pyrene metabolite was quantified. The results show that workers at the airport have high jet fuel dermal exposure. However, the mean pyrene exposure levels were reduced to 33% when they use masks during work. Urinary 1-hydroxypyrene was detected as the biological measure to quantify the internal exposure to PAHs present in JP fuels whose concentration was relatively low (range 35 and 174 nmol) when compared to dermal exposure levels. Workers exposed to 6 hour per day or more had significantly high prevalence of physical disorders (OR=3.17, 95% CI=1.33-7.12). Neurasthenic symptoms (e.g. energy loss, fatigue, fainting, twitching, sleeplessness, irritability, body aches) were found in 58% of the subjects and were associated with years of involvement in job. In aviation industry, working at the airport for ten years or more attributed substantial development of neurasthenic effects (OR=3.85, 95% CI=1.71-8.84). Results of multiple regression analysis revealed mass balance between dermal pyrene dose and 1-hydroxypyrene excretion that confirmed the relevance of the dermal exposure route.

### **P03.4050. Pulmonary Dysfunction in Indium Tin Oxide Exposed Workers**

Saou-Hsing Liou

*Saou-Hsing Liou<sup>1</sup>, Yuan-Ting Hsu<sup>2</sup>, Ting-Yao Su<sup>2</sup>, Cheng-yu Chen<sup>3</sup>*

*1. National Institute of Environmental Health Sciences, National Health Research Institutes, Miaoli County,, Please Select, Taiwan.*

*2. Graduate Institute of Life Sciences, National Defense Medical Center, , Taipei, Taiwan.*

*3. Institute of Labor, Occupational Safety and Health, Ministry of Labor, New Taipei, Taiwan.*

**Abstract:** Aim: To investigate the relationship between indium exposure and lung effects markers among indium tin oxide (ITO) manufacturing workers without job change. Methods: We enrolled 179 male workers from ITO target manufacturing and recycling factories in Taiwan. All workers were categorized into three groups---high exposure, low exposure, and reference group. Plasma indium (P-In), urine indium (U-In) and creatinine adjusted U-In (U-In/Creat.) were used as internal dose of indium exposure. Plasma Krebs von den Lungen-6 (KL-6) and surfactant protein D (SP-D) were used as markers of interstitial pneumonitis. Forced vital capacity (FVC), forced expiratory volume at 1st second (FEV1), and FEV1/FVC ratio were also evaluated by spirometry. Demographics and potential confounders were collected by a self-administered questionnaire. Results: Compared to reference group, significantly increased levels of P-In, U-In, and U-In/Cre were observed in high exposure group and low exposure group. After adjusted for covariates by linear regression, plasma, urinary and creatinine adjusted indium were increased in high exposure group and low exposure group with comparison to reference group. Plasma KL-6 was higher in high exposure group ( $\beta=0.24$ ,  $p<0.05$ ) compared to reference group, but not for surfactant protein D (SP-D). Furthermore, FVC and FEV1 were reduced in both high exposure group (FVC:  $\beta=-0.08$ ,  $p<0.01$ ; FEV1:  $\beta=-0.05$ ,  $p<0.05$ ) and low exposure group (FVC:  $\beta=-0.06$ ,  $p<0.05$ ) compared to reference group. Conclusion: Our findings indicate indium exposure was related to restrictive lung dysfunction, decreased lung function for both FEV1 and FVC test but not for FEV1/FVC ratio. Meanwhile, increased plasma KL-6 in high exposure group also supports that indium exposure results in increased risk of interstitial pneumonitis among direct indium exposure workers. Our study provided an explanation to the consequence of indium exposure- interstitial pneumonitis-restrictive lung dysfunction.

### **P03.4060. The Effect on Workers of Indoor Air Quality in Underground Commercial Spaces**

Mi Jung Jang

*Mi Jung Jang<sup>1</sup>, Jeong Hoon Kim<sup>1</sup>, Kyo Sang Kim<sup>1</sup>*

*1. Department of Environmental Health Research, Seoul Medical Center, Seoul, Korea (the Republic of).*

**Abstract:** Background/Aim Indoor air quality in underground commercial spaces can affect the health of workers and trigger illnesses such as sick building syndrome (SBS), which causes symptoms such as headaches and coughing. This study conducts a survey of the current indoor air quality in underground commercial spaces in the Seoul metropolitan area and determines the associated health effects on workers in underground commercial spaces using a self-reporting questionnaire. Methods Indoor air quality concentrations (temperature, humidity, CO, CO<sub>2</sub>, total culturable bacteria and fungi, total volatile organic compounds and formaldehyde) were obtained in underground commercial spaces. The health effects on 314 workers in commercial spaces were determined by analyzing the results of self-reporting questionnaires relating to subjective symptoms. Results In the environmental assessment questionnaire, 34.4% of the respondents reported having smelt musty odors, and 28.0% had smelt unpleasant odors in the work space for the past month. Health effects relating to SBS were the highest. Skin and mucous membrane, mental, respiratory, and systemic symptoms were reported to have been experienced by 71.0%, 64.3%, 56.1%, and 50.0% of respondents during the past month. SBS symptoms of workers were positively correlated with indoor air quality parameters. Odor, humidity, and cognitive indexes were related more to skin mucosal symptoms than to other symptoms. Furthermore, these symptoms were related to business types and were especially common in workers within the fashion goods industry. Conclusions Results indicate that people who work within the fashion goods industry are more likely to be exposed to a greater amount of indoor air pollutants than those working in other industries. In future studies, it is necessary to evaluate the relationships between indoor air quality in the workplaces and business types.

### **P03.4070. The Impact of an Occupational Injury on Developing Psychiatric Disorders in Taiwan**

Weishan Chin

*Weishan Chin<sup>1</sup>, Shin-Chun Pan<sup>2</sup>, Shih-Cheng Liao<sup>3</sup>, Yue Leon Guo<sup>1</sup>*

*1. National Institute of Environmental Health Sciences, National Health Research Institutes, Zhunan, Taiwan, Taipei, Taiwan.*

*2. Institute of Occupational Medicine and Industrial Hygiene, National Taiwan University, Taipei, Taiwan.*

*3. Department of Psychiatry, National Taiwan University (NTU) and NTU Hospital, Taipei, Taiwan.*

**Abstract:** Background: Injuries are known to be a relevant risk factor for psychiatric disorders. Psychiatric disorders were found increased after occupational injury, and such increase was observed up to six years after injury. However, comparison with uninjured workers was not done. Objective: To assess the impact of occupational injury compared with non-occupational injury and no injury on developing psychiatric disorders in Taiwan working population. Method: We used Taiwan's National Health Insurance Research Database (NHIRD) to investigate the incidence of suicidal attempt, traumatic stress related disorders, depressive disorders, anxiety, and substance and alcohol abuse and dependence in one million Taiwan people. Patients aged between 20 and 50 in 2000, were employed, did not have any injury before 2000, and did not suffer psychiatric disorders before 2000 and injury event were included. All participants were classified into three groups such as suffering an occupational injury, non-occupational injury, and no injury. Individuals in each group were matched by age, sex, insured salary while injury or diagnosed happened, and calendar year of injury happened. Data were analyzed by survival analysis and adjusted for age, sex, insured salary before injury. Results: A total of 12,528 patients was included into final analysis. Compared with uninjured workers, occupational injury was associated with a higher risk of suicidal attempt (Hazard Ratio, HR=21.47, 95% CI=2.89-159.31), traumatic stress related disorders(HR=1.60, 95% CI=1.07-2.39), depressive disorders (HR=1.91, 95% CI=1.50-2.43), anxiety disorders (HR=1.46, 95% CI=1.26-1.68 ), and substance and alcohol abuse and dependence(HR=2.67, 95% CI=1.71-4.19). Furthermore, we found that works with non-occupational injury had similar increased risk of developing psychiatric disorders. Conclusion: In this fourteen years follow-up study, we found that injury increased risks of developing suicide attempt and psychiatric disorders.

### **P03.4080. Epidemiological Profile of Poisoning in Workplace Compulsory Notifications in the Brazilian Notifiable Diseases Information System from Municipalities of São Paulo State**

Ana Paula Sacone da Silva Ferreira

*Mariana T. Guimaraes<sup>1</sup>, Ana Paula Sacone da Silva Ferreira<sup>2</sup>, Alessandro Jose Nunes da Silva<sup>3</sup>, Sandra Renata Duracenko<sup>3</sup>, Simone Alves dos Santos<sup>4</sup>, Rodolfo Andrade de Gouveia Vilela<sup>2</sup>, Maria Regina Alves Cardoso<sup>1</sup>*

*1. Epidemiology, School of Public Health, University of Sao Paulo, Sao Paulo, SP, Brazil.*

*2. Environmental Health, School of Public Health, University of São Paulo, São Paulo, São Paulo, Brazil.*

*3. Centro de Referência em Saúde do Trabalhador, Secretaria Municipal de Saúde, Piracicaba, São Paulo, Brazil.*

*4. Centro de Vigilância em Saúde, Secretaria de Estado de Saúde de São Paulo, São Paulo, São Paulo, Brazil.*

**Abstract:** The Brazilian Notifiable Diseases Information System (SINAN) introduced, in the middle of 2007, forms for reporting injuries and diseases related to work by every health care unit in the country. Therefore, this study aimed to describe the epidemiological profile of the poisoning in workplace notifications for three São Paulo State municipalities from 2008 to 2014. This was a descriptive time-series study. Data were collected from the SINAN for the municipalities of Araraquara, Piracicaba and Campinas from 2008 to 2014. Data were processed and evaluated using STATA software. The variables analysed were: sex, age, occupation, toxic agent, health unit attendance, route of exposure, and exposure circumstance. Trend in the number of notifications was assessed by a Prains-Winsten regression model. A total of 367 occupational poisoning events (75.2% among men, 24.8% among women) were notified in the study period, including 7 cases involving underage workers. The age mean was 35 years (SD=12). Most of the notifications were attended in primary health care (82.4%), and 29.3% among petrochemical operators. The most common groups of toxic agents were industrial chemical products (64.6%) followed by pesticides (16.9%). Regular use of the toxic agent was the main poisoning circumstance (71.1%). Accidental events came as the second more usual circumstance of intoxication (18.8%). Regarding the exposure route, the respiratory was the mean route (80.4%), followed by dermal contact (11.7%). The study revealed a decrease of 12 notifications number per year in the study period. As far as it is known, this was the first study that described the profile of poisoning in workplace for these municipalities with SINAN data. The number of notifications was low suggesting important underreporting, considering the profile of the municipalities, and the contingent of workers at risk. Moreover, the decrease in notifications over the years indicates a worsening of this injurie surveillance.

**P03.4110. Profiling Noise Induced Hearing Loss among Selected Auto-Rickshaw Drivers in Chennai City, India: A Pilot Study**

Krishnendu Mukhopadhyay

*Krishnendu Mukhopadhyay<sup>1</sup>, N S Hari Krushna<sup>1</sup>, Banani H. Mukhopadhyay<sup>2</sup>, Sankar Sambandam<sup>1</sup>*

*1. Environmental Health Engineering, Sri Ramachandra Medical College and Research Institute, Chennai, India, Chennai, Tamil Nadu, India.*

*2. Department of Chemistry, Women's Christian College, Chennai, Tamil Nadu, India.*

**Abstract:** Background: The main reasons of city noise pollution in India are vehicle density and traffic congestion. Frequent travelling in auto-rickshaws in most of Indian urban areas may lead to noise-induced hearing loss (NIHL) where drivers are primary victims followed by its daily passengers and outside commuters. This study was conducted to evaluate the prevalence of NIHL among auto rickshaw drivers in three selected routes in Chennai city, India. Methods: Thirty drivers with age-range between 26 and 58 years and a minimum of five years driving experience were included in this study. As per questionnaire records, they had no history of hearing disabilities at the beginning of this profession. Noise Dosimeter was used to assess personal noise and pure-tone audiometric testing was conducted to quantify hearing loss for all participants. In an average, they were found to have on driving mode for about 4 hours and would wait in auto-rickshaw stands for another 4 hours during 8 hours personal monitoring. Consequently, a few stand areas were monitored using Sound Level Meter (SLM) to assess background noise. Measurements were taken thrice within three consecutive months starting from January 2016. Relevant questionnaires and participants' informed consents were also taken into account for ethical approval from the institute. Results: Average 8 hours personal exposures and area noise levels were recorded as 92.02 and 79.30 dBA, respectively; higher than prescribed permissible limits. Among all participants, 23 (76.7%) were found to have noise induced hearing loss as diagnosed by Air and Bone Conduction tests. Conclusion: Studies on noise exposure assessment among auto-rickshaw drivers are still inadequate in India. Despite a few limitations of recruiting auto-drivers in larger scale, the findings of this study would encourage to conduct more organized epidemiological studies on hearing loss even for long-distance professional drivers.

### **P03.4120. Can Time-Lapse Photography Improve Task-Specific Risk Characterization in Informal Labor Sectors?**

Zoey Laskaris

*Zoey Laskaris<sup>1</sup>, Chad Milando<sup>2</sup>, Stuart Batterman<sup>2</sup>, Julius Fobil<sup>4</sup>, Nil Basu<sup>3</sup>, Marie O'neill<sup>1</sup>, Thomas Robins<sup>2</sup>*

**Abstract:** Aim: To generate time-activity patterns (TAPs) using time-lapse photography and describe differences in particulate matter (2.5 and 10 $\mu$ m) concentrations ( $\mu$ g/m<sup>3</sup>) across job tasks among informal electronic-waste (e-waste) recovery workers in Accra, Ghana. Background: Many of the highest occupational exposures occur in informal occupational sectors among unprotected workers around the globe. Characteristics of informal sectors present challenges in capturing these exposures and linking them to work tasks; informal work settings often lack defined physical and organizational structure and a consistent work-flow. A common method used in occupational settings to identify job tasks associated with health and safety hazards are time-activity diaries (TAD). These diaries may be limited in their ability to capture the high variability in tasks and short-term peak exposures characteristic of informal sectors. Moreover, they can be cumbersome for the participants and with low validity. An improved method may be the use of time-lapse photography to render individual TAPs with high resolution without relying on worker self-report. Method: The participants are enrolled in a prospective occupational cohort study, GeoHealth-II based in Accra, Ghana. 100 informal e-waste worker participants wore air sampling backpacks during a work shift. Backpacks are equipped with a front-mounted GoPro camera, and real-time and gravimetric (filter-based) particulate matter sampling devices (sizes 2.5 and 10 $\mu$ m). Additionally, participants filled out a standard TAD with a 30-minute resolution. We developed a data collection tool to log all activities and relevant photo details identified in the photos and interviewed workers to validate our task assignments. Results: This poster will describe our method of generating TAPs and our results based on its application. Results include tasks performed on an e-waste site (type and duration) and their corresponding PM (2.5 and 10 $\mu$ m) concentrations ( $\mu$ g/m<sup>3</sup>).

### **P03.4130. Relationship between Blood Lead Levels and Dietary Essential Mineral Intake in Electronic Waste Workers and a Control, in Ghana**

Sylvia Takyi

*Sylvia A. Takyi<sup>1</sup>, Julius Fobil<sup>1</sup>, John Arko-Mensah<sup>1</sup>, Nil Basu<sup>4</sup>, Thomas Robins<sup>3</sup>, Afua A. Amoabeng<sup>1</sup>, Karel G. Houessionon<sup>2</sup>, Augustine Acquah<sup>1</sup>, Lawrencia Kwarteng<sup>1</sup>*

*3. Environmental Health Sciences, University of Michigan, Ann-Abor, MI, United States.*

*4. Natural Resource Sciences, McGill University, Montreal, QC, Canada.*

**Abstract:** Background: Several toxic metals are known to interact with, and affect absorption of micro nutrients in the gastro-intestinal tract. Although studies have reported high levels of lead (Pb) in electronic waste (e-waste) workers, the possible interaction and impact on availability of essential minerals in the body have not been extensively studied. Objectives: The aim of this study was to investigate the relation between blood lead levels (BLL) and dietary essential mineral (Ca, Fe, Mg, Zn, Cu) intakes of e-waste workers and a control group. Methods: This prospective cohort study, which is part of the ongoing West Africa GEOHealth II project, compared 100 e-waste workers at Agbogbloshie (exposed) to 50 controls (unexposed). 10 ml of whole blood was collected and analyzed for Pb using the Inductively Coupled Plasma Mass Spectrometry (ICP-MS). Essential mineral intakes were assessed using a 2 day 24 hour recall and analyzed by the Esha F-Pro nutrition software. Statistical analysis was done using SPSS (Version 22). BLL and essential minerals were reported using means, standard deviations (SD) and ranges. Results: Overall, mean (SD) BLL was higher ( $9.24 \pm 6.37 \mu\text{g/dL}$ ) in e-waste workers, range (2.42-41.60  $\mu\text{g/dL}$ ) than the control group ( $4.10 \pm 1.92 \mu\text{g/dL}$ ), range (1.51-14.04  $\mu\text{g/dL}$ ). BLL levels were mostly above 10  $\mu\text{g/dL}$  at e-waste site (28%), compared to control site (2%). Mean intakes of Ca, Zn, Cu and Mg in the diet were low in both groups, but Fe was adequate. A simple linear regression model showed a positive relationship between BLL and Ca intake ( $r = 0.39$ ,  $p < 0.001$ ). Conclusions: Diet taken lacked adequate levels of Zn, Cu and Mg among all study participants. There was a positive relationship between Ca levels and BLL. This preliminary data suggests the need to supplement existing dietary intake with certain micronutrients. Key Words: Essential minerals, Lead, Whole Blood, E-waste, Ghana
