

ISES-ISEE 2018  
JOINT ANNUAL MEETING

ABSTRACT BOOK

OTTAWA-CANADA  
26-30 AUGUST

Addressing Complex Local and  
Global Issues in Environmental  
Exposure and Health

[www.isesisee2018.org](http://www.isesisee2018.org)

## Table of Contents

<b>PLENARY &amp; ORAL SESSIONS</b> .....	10
Sunday, August 26 .....	10
The Role of Occupational Studies in Expanding Our Knowledge of Environmental Carcinogens.....	10
Monday, August 27 .....	11
Climate Change: the Greatest Public Health Challenge of Our Time .....	11
The Health of the Land and Our Culture: Indigenous Rights as Pathways to Healthy Environments	12
O01.01A. Chemical Exposures and Fish Consumption .....	13
O01.01B. Occupational Exposures and Respiratory Outcomes .....	17
S01.01A. Addressing Complex Local and Global Issues in Environmental Exposure and Health: Addressing the Health of Children and Adolescents .....	21
S01.01B Air Pollution and Physical Activity: Environmental Health Perspective .....	25
S01.01C. Air Pollution Exposure and Metabolomics .....	29
S01.01D. Bronchiolar and Interstitial Lung Disease by Occupational and Environmental Exposure: Their Implication and Future Task to Be Solved for Health Protection.....	33
S01.01E. Climate, Air Pollution, and Environmental Health in Africa 1 .....	37
S01.01F Complex Rural Exposures and Health.....	41
S01.01G. Evaluating High-Throughput New Approach Methods (NAM) for Exposure .....	45
S01.01H. Harmonization of Biomonitoring Measurements: Approaches Used by Laboratory Networks in Canada, Europe and the United States .....	49
S01.01I. Mobilizing Data for Healthy Environments: Platforms Facilitating Health and Environmental Exposure Linkage .....	53
S01.01J. Multi-Response and Multi-Pollutant Models for Environmental Exposure and Health: From Gap-Filling to Decorrelating Structure in Data .....	57
S01.01K. Novel Methods for Assessing Complex Exposure Mixtures in Environmental Epidemiology .....	61
O01.02A. Cancer and the Environment.....	65
O01.02B. Cardiopulmonary Outcomes Associated with Long-Term Exposure to Air Pollution.....	71
O01.02C. Characterizing Near-Road and Point Sources of Air Pollution.....	78
O01.02D. Climate and Health.....	84
O01.02E. Environmental Exposures and Adult Health Outcomes .....	90
O01.02F. Exposures and Health Impacts of Perfluorinated Substances .....	97
O01.02G. Exposures in Contaminated Communities and Children's Health .....	102
O01.02H. Neurodevelopmental Outcomes Associated with Perinatal Exposure to Air Pollution..	108
O01.02I. New Policy Directions in Exposure Assessment and Environmental Epidemiology .....	114
S01.02A. Advances in Air Pollution Exposure Assessment for Population Health Studies in Low and Middle Income Countries: Insights from India and Beyond.....	119

S01.02B. High-Resolution Metabolomics: A Platform Linking the External and Internal Environment .....	124
S01.02C. Investigating Chemical Constituents and Exposure Potential in Recycled Tire Crumb Rubber Infill Used in Playing Fields and Playgrounds: State, Federal, and International Governmental Perspectives .....	130
S01.02D. Sound Off for Environmental Noise Research: Milestones in Exposure Assessment and Health Evidence.....	136
O01.03A. A Closer Look At Exposures to Flame Retardants .....	141
O01.03B. A Global Look at Lead Exposures.....	147
O01.03D. Effects of Heat Waves .....	153
O01.03E. Environmental Exposures and Birth Outcomes.....	159
O01.03F. Natural Environment and Health.....	165
O01.03G. Occupational Exposure and Worker Health.....	171
O01.03H. Panel Studies of Air Pollution, Inflammation, COPD, and Lung Function .....	177
O01.03I. Social, Economic, and Demographic Disparities in Air Pollution Exposure and Health Outcomes .....	183
O01.03J. Transportation System and Health.....	189
O01.03K. Stress, Inflammation, and Cardiopulmonary Outcomes in Scripted and Experimental Air Pollution Exposure Studies.....	195
S01.03A. Effects of Prenatal Exposure to Environmental Neurotoxicants on Health and Neurodevelopment .....	201
S01.03B. Food, Nutrition and Environmental Health among First Nations in Canada.....	208
S01.03C. High Resolution Air Pollution Mapping: Translating Data to Action .....	214
O01.04A. Air Pollution, Asthma and Allergic Disease .....	219
O01.04B. Application of Machine Learning Methods to Develop Spatiotemporal Models of Air Pollution .....	225
O01.04C. Neurological and Cognitive Outcomes Associated with Air Pollution.....	230
O01.04D. Novel Approaches in Environmental Epidemiology .....	233
O01.04E. Prenatal Metals Exposure .....	238
S01.04A. Addressing Complexities through Partnership and Collaboration in the Arctic .....	245
S01.04B. Aggregate Exposure and Cumulative Risk Assessments in the Euromix Project .....	249
S01.04C. Assessing Health and Well-Being Benefits of Exposure to Natural Environments: Methodological Challenges and Opportunities.....	254
S01.04D. Biomonitoring Data from the Canadian Health Measures Survey in Risk Assessment: A Decade of Progress.....	258
S01.04E. Clean Cooking Implementation Science to Understand Complex Determinants of Clean Fuel Technology Adoption.....	263
S01.04F. Climate, Air Pollution, and Environmental Health in Africa 2 .....	268
S01.04G. Emerging Evidence on Exposures to Ultrafine Particles .....	272

S01.04H. Updates on the CKDu Epidemic and New Directions for Coordinated Research .....	276
Tuesday, August 28 .....	280
WHO Global Strategy on Health, Environment and Climate Change.....	280
How Can Birth Cohort Studies Contribute to Knowledge and Policies of the World to Reduce Risks of Emerging Contaminants? .....	281
O02.01A. Air Pollution and Diabetes .....	282
O02.01B. Air Pollution Related Hospitalization, Mortality, and Life Expectancy .....	287
O02.01C. Methods in Occupational Exposure Assessment.....	292
O02.01D. Predicting Indoor Particulate Matter Concentrations .....	297

## PLENARY & ORAL SESSIONS

Sunday, August 26

The Role of Occupational Studies in Expanding Our Knowledge of Environmental Carcinogens

*Paul Demers, Occupational Cancer Care Ontario, Canada*

**Abstract:** Exposure to environmental contaminants are generally orders of magnitude higher in workplaces than in environmental settings. In addition, occupationally exposed populations are often easy to identify and assess levels of exposure. Because of this, environmental health effects are generally recognized much earlier in workers than in the general population. A classic example that is often used is uranium miners and radon, but there are many more and, in fact, much of what we know of environmental cancer was initially identified in workplace studies. The evaluations of the International Agency for Research on Cancer (IARC) present an excellent opportunity to examine this and recent examples include diesel engine exhaust and pesticides. Well over half of all IARC definite (Group 1), probable (Group 2A), and possible (Group 2B) human carcinogens are occupational. These include industrial chemicals, metals, particles, and radiation, most of which can be encountered in community as well as work settings. The classification of almost all Group 1 occupational carcinogens was based on epidemiologic evidence from workplace studies. While many environmental carcinogens are more easily studied in workplaces, there are some situations where occupational evidence does not work. These include situations where exposures are higher, or occur primarily in, communities and not in workplaces, which may be the case with environmental tobacco smoke or some rare exposures, such as erionite. Another situation is where the excess risk is among a susceptible population, such as the old or young or a genetically predisposed sub-population. A last example is where relative risks are small and only the large environmentally exposed populations provide adequate power (e.g. ambient air pollution). It is essential to continue conducting studies of both occupational and community exposure to expand our knowledge of environmental cancer.

Monday, August 27

Climate Change: the Greatest Public Health Challenge of Our Time

*Gina McCarthy, Harvard T.H. Chan School of Public Health, Boston, MA, USA*

Abstract: Public mistrust of scientists is growing, and a broad anti-scientific movement has gained momentum in the United States that has fueled the enactment of policies at the federal, state and even local levels that threaten public health protections, including actions to mitigate and adapt to our changing climate. The causes of mistrust in science are many and include ineffective or absent engagement of scientists with audiences outside academia and the publication of studies with conflicting results, which fosters confusion and doubt about science among the public. At the same time, science is the backbone of innovation and entrepreneurship that has underpinned efforts to protect public health and natural resources, as well as our economic strength. Given the increasingly complex nature of today's challenges, it is more critical than ever that government officials, business leaders and the general public have access to sound science communicated in ways that allows them to see its relevance to our health and wellbeing. This is particularly true for the issue of climate change; addressing climate change affords the greatest opportunity to improve health in this century. The decisions we make now about how we use energy, harness natural resources, and conduct our lives can improve our health today and provide for a more equitable world for generations to come. The profound challenges that come with climate change and other threats to the global environment will not be solved overnight or without sound science, large investments in technology innovation, and actions across all sectors of society.

## The Health of the Land and Our Culture: Indigenous Rights as Pathways to Healthy Environments

*Eriel Deranger, Indigenous Climate Action, Canada*

Abstract: Indigenous communities are often at the forefronts of Environmental racism. While there are increasing trends of Indigenous peoples moving to cities, their culture, identity and rights are intrinsically connected to healthy lands and eco-systems. Heavy resource extraction upstream, or directly adjacent to, Indigenous lands and territories has led to a host of serious violations to the health, safety and survival of Indigenous communities and rights in Canada. The Alberta tar sands poses one of the most striking examples of how Industrial development has led to the degradation of water, lands, food security and the rights of the Cree, Dene and Metis peoples. Resources extraction is just one example of neo-colonialism - continued inaccessibility to adequate resources, housing, food, water, sanitation and decision making processes has allowed environmental racism to continue unabated in the country. Indigenous ways of living model exemplary low carbon lifestyles. By honoring and implementing Indigenous rights and peoples into land management processes we can find ways and means to achieve true environmental justice. This keynote will explore how Indigenous rights and knowledge are key to addressing the most complex challenges related to the health and safety of our communities.

## 001.01A. Chemical Exposures and Fish Consumption

### 001.01.01. Examining Changes in Persistent Organochlorine Pollutants Following High Consumption of Farmed Atlantic Salmon: Results from an 8-Week Dietary Intervention Study

Thorhallur Halldórsson

*Thorhallur I. Halldórsson<sup>1</sup>, Stefan Voorspoels<sup>2</sup>, Ingibjörg Gunnarsdóttir<sup>1</sup>, Inga Thorsdóttir<sup>1</sup>, Alfons Ramel<sup>1</sup>*

- 1. Faculty of Food Science and Nutrition, University of Iceland, Reykjavik, Iceland.*
- 2. Flemish Institute for Technological Research (VITO), Mol, Flanders, Belgium.*

**Abstract:** Background: In 2004 a publication in Science by Hites et al. reported a 10 to 100-fold higher concentrations of persistent organochlorine pollutants (POPs) in farmed Atlantic salmon compared to wild Pacific salmon. These findings generated intense debate on the health-risk-benefits of farmed Atlantic Salmon. Objective: To examine the short-term effect of high consumption of farmed Atlantic salmon on serum POP concentrations. Methods: A 4-arm randomized controlled trial in overweight or obese subjects (BMI: 27.5-32.5 kg/m<sup>2</sup>) assigned to energy-restricted seafood diet over an 8-week period (SEAFOOD-plus, 2004-2005, n=324). Controls were assigned to a fish free diet and one arm was assigned to three meals per week of farmed Atlantic salmon (24 meals), matched for energy. Of these participants 20 male cases (Salmon) and 20 male controls were selected who experienced modest weight loss and concentrations of pp-DDE, HCB and PCBs (congeners no. 118, 138, 153, 170, 180) were measured at baseline and endpoint. Results: Median baseline concentrations for sum of PCBs, pp-DDE and HCB were 1.41, 0.78 and 0.16 ng/mL, respectively. Mean weight loss at endpoint was 4.8kg and 4.5kg in the salmon and control group (p=0.68), respectively. Concentrations of EPA and DHA were significantly increased at endpoint by ~32% in the Salmon group but reduced by ~14% in controls, suggesting compliance to the intervention. At endpoint the mean sum of PCBs was increased by 0.36ng/mL in the salmon group (p=0.22). Lack of significance is unlikely to be explained by weight loss during the intervention as only a minor change of -0.06ng/mL (p=0.84) in PCB concentrations were observed among controls. Individual PCB congeners, pp-DDE and HCB were non-significantly but systematically increased by 6 to 41% of mean levels in the salmon group compared to controls. Conclusion: Our study suggests that high consumption of farmed Atlantic Salmon over a short period does not substantially affect circulating POP levels.

## **001.01.02. Shellfish and Fatty Fish Intake and Fecundability in a North American Prospective Cohort Study**

Lauren Wise

*Lauren A. Wise<sup>1</sup>, Sydney Willis<sup>1</sup>, Amelia K. Wesselink<sup>1</sup>, Katherine Tucker<sup>2</sup>, Ellen M. Mikkelsen<sup>3</sup>, Kenneth J. Rothman<sup>1</sup>, Marco Vinceti<sup>4</sup>, Henrik T. Sorensen<sup>3</sup>, Elizabeth E. Hatch<sup>1</sup>*

*4. Environmental, Genetic, and Nutritional Epidemiology Research Center - CREAGEN, Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy.*

Abstract: Fatty fish and shellfish are important sources of omega-3 fatty acids, which may improve embryo morphology and fecundity. However, they are also sources of persistent organic pollutants and heavy metals, which may adversely affect fecundity. In a French retrospective cohort study of 3,421 pregnant women, shellfish intake  $\geq 2$  times/week (relative to  $< 2$  times/month) was associated with a 21% reduction in fecundability (average per-cycle probability of conception); fish intake showed little association with fecundability. There have been no prospective studies of these associations. We evaluated intakes of shellfish, fatty fish, and marine fatty acids (sum of eicosapentaenoic acid, docosahexaenoic acid, and docosapentaenoic acid) in relation to fecundability in a prospective cohort study of 3,292 female pregnancy planners from the United States and Canada. At enrollment, women completed a baseline questionnaire on sociodemographics, anthropometrics, behavioral factors, and medical history, and a validated food frequency questionnaire (NIH diet history questionnaire II). Pregnancy status was updated bimonthly for 12 months or until pregnancy, whichever came first. We estimated fecundability ratios (FR) and 95% confidence intervals (CI) using proportional probabilities regression models, adjusted for energy, age, body mass index (BMI), smoking, alcohol, physical activity, intercourse frequency and timing, multivitamin use, race/ethnicity, education, marital status, and parity. We restricted analyses to women with  $\leq 6$  menstrual cycles of attempt time at enrollment. Greater shellfish intake was associated with slightly reduced fecundability ( $\geq 4$  servings/month vs. none: FR=0.87, 95% CI: 0.72-1.07). The shellfish association was stronger among non-users of fish oil supplements (FR=0.77, 95% CI: 0.61-0.98), particularly overweight women (BMI  $\geq 25$  kg/m<sup>2</sup>: FR=0.69, 95% CI: 0.48-1.01). Intakes of fatty fish and marine fatty acids were not appreciably associated with fecundability.

### **001.01.03. Seafood Consumption and Mercury Exposure in Chicago Asian Communities**

Mary Turyk

Abstract: The Asian population in the U.S. has an elevated mean blood mercury compared with the non-Asian population due to higher frequency of fish consumption. Methyl mercury (MeHg) crosses the placenta and has been shown to affect neurodevelopment in the fetus as well as cardiovascular risk in adults. However, nutrients in fish, such as omega-3 fatty acids (n-3 FA), have beneficial effects on these health endpoints. Thus, fish consumption advice should balance the risks and benefits. We conducted a community assessment of 367 Chinese, Koreans and Vietnamese in Chicago consisting of a survey of fish consumption and cultural dietary practices; hair sampling for Hg; and Hg testing of commonly consumed seafood purchased in Chicago. Mean participant age was 42 years (range 18, 80); 87% were female; 53% had an annual income of <\$20,000 or were eligible for supplemental food assistance; 95% were born outside of the US; and 41% spoke only non-English at home. Seafood consumption preferences varied among the ethnic groups and included species with a range of contaminant and n-3 FA levels. Mercury intake from fish ( $\mu\text{g}/\text{kg}\text{-day}$ ) differed significantly by ethnicity, with the highest intake in Koreans and the lowest in Vietnamese. n-3 FA intake from fish ( $\text{mg}/\text{kg}\text{-day}$ ) was also highest in the Koreans, predominantly due to anchovy consumption. Elevated hair Hg levels ( $>1\mu\text{g}/\text{g}$ ) were detected in 28% of Vietnamese, 18% of Chinese and 11% of Korean participants. Factors significantly associated with hair mercury levels included mercury intake from consumption of fish with low, moderate and high Hg; consumption of locally caught fish; higher BMI; hair dye use; and a less Western-acclimated dietary pattern. These findings will be used to develop messages to decrease exposure to contaminants while maintaining consumption of healthy nutrients in fish in these communities.

#### **O01.01.04. Biomonitoring of Mercury and Persistent Organic Pollutants in Michigan Urban Anglers and Association with Fish Consumption**

Abstract: The 32-mile Detroit River and surrounding tributaries have been designated as a Great Lakes Area of Concern due to pollution from decades of municipal and industrial discharges, sewer overflows and urban development. Key pollutants in fish samples from the Detroit River include mercury, polychlorinated biphenyls (PCBs), dichlorodiphenyldichloroethylene (DDE), dioxins and furans. A biomonitoring study was conducted to assess exposures to these persistent toxic substances in Detroit urban anglers who may be at higher exposure risk due to consumption of locally caught fish. Using a modified venue-based sampling approach, 287 adult shoreline anglers along the Detroit River were recruited and participated in the program. Study participants provided blood and urine specimens and completed a questionnaire interview. We examined percentile estimates for total blood mercury, PCBs, DDE, and dioxin-like total toxic equivalency (TEQ) concentrations among study participants compared with the general U.S. population. Multiple linear regression was used to identify important predictors of contaminant concentrations. Quantile regression was used to investigate whether eating locally caught fish had a differential effect at various quantiles of each contaminant. Participants reported eating an average of 20 Detroit River caught fish meals in the past year. The Detroit urban anglers' total blood mercury and PCB concentrations were 2 to 3 times higher than the general U.S. population. Elevated levels of DDE and total TEQ concentrations were not observed in the cohort. Eating more locally caught fish was associated with higher total blood mercury and serum PCB concentrations, and this effect had a larger impact at higher quantiles of these biomarkers. The biomonitoring data served to inform public health officials and guide state and local public health actions to reduce harmful exposures.

## O01.01B. Occupational Exposures and Respiratory Outcomes

### **O01.01.05. Personal and Area Exposure Assessment at a Stainless Steel Fabrication Facility: Evaluation of Inhalable, Thoracic, Time-Resolved PM<sub>10</sub>, and Lung-Deposited Airborne Metals**

Ashley Newton

Abstract: Occupational exposure to multivalent transition metals in welding fume is associated with a variety of adverse health outcomes, including respiratory and cardiovascular impairment, lung cancer, and metal fume fever. Welding fume was designated a Group 1 carcinogen by an International Agency for Research on Cancer (IARC) working group in 2017 and a lack of data on deposition and clearance of welding fume was identified as a gap in the scientific literature. We conducted a detailed exposure assessment of 18 welders (monitoring two work shifts per person) in a stainless steel fabrication facility, evaluating personal exposure to inhalable and lung-deposited PM and airborne metals as well as area thoracic PM and time-resolved PM<sub>10</sub> airborne metals. Urinary metals biomarkers were also measured pre and post shift. Mean area thoracic PM exposure in each of the three shops was 30.1, 214, and 164  $\mu\text{g}/\text{m}^3$ , respectively on the first day of sampling. During all sampled shifts, 14 area PM<sub>10</sub> airborne metals were measured with 15 minute time resolution and concentration time-series were produced for each day. In the largest shop, mean area chromium exposure was 19.5  $\mu\text{g}/\text{m}^3$ , mean area manganese exposure was 32.3  $\mu\text{g}/\text{m}^3$ , and mean nickel exposure was 5.8  $\mu\text{g}/\text{m}^3$  over the measured shift. Lead, tungsten, copper, molybdenum, and vanadium exposure were all highly variable, exhibiting short-duration peaks of varying intensities. Although there is currently no quantitative occupational exposure limit for welding fume, the workers at this facility were exposed to high levels of inhalable PM and metal-specific welding fume components within biologically relevant size fractions.

**O01.01.06. Association between Occupational Exposure to Textile Fibre Dusts and Lung Cancer in a Population-Based Case-Control Study in Montreal: A Preliminary Analysis Comparing Results from Three Analytical Methods**

Mengting Xu

*Mengting Xu<sup>1</sup>, Vikki Ho<sup>1</sup>, Mireille Schnitzer<sup>1</sup>, Jack Siemiatycki<sup>1</sup>*

*1. University of Montreal, Montreal, QC, Canada.*

**Abstract:** Objectives: To compare results estimated using two causal inference methods, inverse probability of exposure weighting (IPEW) and G-computation, to that estimated using the conventional multivariable logistic regression, on the association between occupational exposure to textile fibre dusts and lung cancer risk. Methods: A population-based case-control study on lung cancer was conducted from 1996 to 2001 in Montreal, Canada. Cases were individuals diagnosed with incident lung cancer and population controls were randomly selected from electoral lists and frequency-matched to cases by age, sex and electoral district. Questionnaires on lifetime occupational history, smoking and demographic characteristics were collected during in-person interview. Experts reviewed subjects' work history and assessed exposure to 294 agents, including textile fibre dusts. Odds ratios (OR) and their 95% confidence intervals (CIs) for the association between ever exposure to textile fibre dusts and lung cancer risk were estimated using three different methods: 1) IPEW, 2) G-computation, and 3) conventional multivariable regression. Results: The two causal inference methods produced higher point estimates (OR<sub>IPEW</sub>=1.17, 95% CI=0.86-1.57; OR<sub>G-computation</sub>=1.11, 95% CI=0.80-1.49) compared to that estimated using the conventional multivariable logistic regression (OR=0.87, 95% CI=0.68-1.11). However, all three sets of OR results were close to the null value. Conclusion: The different methods provided rather similar results, albeit not identical. They are compatible with a null association between occupational exposure to textile fibre dusts and lung cancer.

## **001.01.07. Chronic Obstructive Pulmonary Disease Mortality in the Diesel Exhaust in Miners Study (DEMS)**

Jacqueline Ferguson

*Jacqueline M. Ferguson<sup>1</sup>, Sadie Costello<sup>1</sup>, Holly Elser<sup>1</sup>, Andreas M. Neophytou<sup>1</sup>, Debra T. Silverman<sup>2</sup>, Ellen A. Eisen<sup>1</sup>*

*2. Division of Cancer Epidemiology & Genetics, Occupational and Environmental Epidemiology Branch, National Cancer Institute, Bethesda, MD, United States.*

Abstract: Miners are routinely exposed to high levels of diesel exhaust emissions from powered equipment. Although biologically plausible, there is little evidence of elevated risk of chronic obstructive pulmonary disease (COPD) in the literature. To fill this gap, we examined COPD mortality and quantitative exposure to diesel exhaust (respirable elemental carbon (REC)) in an existing cohort of highly exposed miners with well characterized long-term exposure history. The Diesel Exhaust in Miners Study (DEMS) included 11,667 male miners who worked at least one year, on the surface or underground, in eight non-metal US mines. We fit Cox proportional hazard models to estimate hazard ratios (HRs) for COPD mortality and 15-year lagged and non-lagged REC exposure. COPD mortality was defined using ICD codes for underlying and contributing causes of death. Based on 130 cases, we categorized cumulative REC exposure into tertiles. Models were stratified by state and adjusted for respirable dust, worker location (surface and underground), race, year of hire, and calendar year, with age as the timescale. Separate models were then fit for all, underground, and surface miners. HRs for 15-year lagged cumulative REC were elevated in the middle (20-463  $\mu\text{g}/\text{m}^3\text{-yr}$ : HR 1.41 (95%CI: 0.80-2.47)) and highest (>463  $\mu\text{g}/\text{m}^3\text{-yrs}$ : HR 1.62 (0.80-3.30)) exposure categories. The HRs in underground workers were slightly stronger (78 cases). Among surface workers (52 cases), those in the highest category (>24  $\mu\text{g}/\text{m}^3\text{-yrs}$ ) had a HR of 3.46 (1.23- 9.74). HRs were attenuated when exposure was unlagged. Our results suggest that REC exposure is associated with increased risk of COPD in both underground and surface workers. The association appears stronger among surface workers, who have exposures far lower than those underground. This may suggest a steeper exposure-response at lower exposures, or the lower HR among underground miners may be due to negative confounding by smoking or healthy worker selection.

## **O01.01.08. Environmental and Biological Monitoring of Volatile Organic Chemicals among Nail Technicians**

Diana Ceballos

*Diana M. Ceballos<sup>1</sup>, Jessica Craig<sup>2</sup>, Xianqiang Fu<sup>3</sup>, Chunrong Jia<sup>3</sup>, Thomas F. Webster<sup>2</sup>, Victoria Fruh<sup>2</sup>, Zoe Petropoulos<sup>2</sup>, Jose Vallarino<sup>1</sup>, MyDzung T. Chu<sup>1</sup>, Joseph G. Allen<sup>1</sup>*

*2. Boston University School of Public Health, Boston, MA, United States.*

*3. University of Memphis School of Public Health, Memphis, TN, United States.*

**Abstract:** The U.S. nail salon industry employs 380,000 workers nationwide, many young Vietnamese women. Numerous solvents are used in nail salons, but no studies have measured personal exposure and biomarkers of nail techs. This study aims to identify key volatile organic compounds (VOCs) in nail salons; explore the relationship between personal exposure and biomarkers; and understand the occupational contribution to VOC biomarkers. Personal and area air samples were collected on 10 nail techs during a work shift in 7 nail salons in the Boston Area (2016-2017). Air samples were collected using thermal desorption tubes and analyzed for 85 VOCs. Whole blood samples were collected for each tech before and after the shift and analyzed for 45 VOCs. Ventilation rates were determined by continuous CO<sub>2</sub> measurements and a steady-state box model. We observed use of personal protective equipment (PPE). Of the VOCs detected in the air and blood samples, toluene and ethyl acetate predominated - which are common ingredients in nail products. The median and range concentrations of toluene and ethyl acetate were, respectively, 12(2-105) and 842(143-2,640)µg/m<sup>3</sup> in indoor air, 39(5-85) and 759(144-2,850)µg/m<sup>3</sup> in personal air, and 0.36(0.028-0.79) and 0.51(0.16-1.48)ng/ml in blood. Blood concentrations and personal exposures displayed moderate but insignificant associations (tol r=0.42 p=0.11; ethyl acetate r=0.43 p=0.21). Blood levels were elevated after the shift (p<0.018), indicating significant contributions from occupational exposure. Ventilation rate median and range were 25(6.4-88)cfm/person, not always meeting the 25 cfm/person guideline for nail salons. Three techs were observed using latex or nitrile gloves throughout their shift; others used latex gloves only for pedicures. Two techs were observed using disposable N95 with charcoal filter sporadically. The results suggest the need for change in nail product formulation, better ventilation, and more effective PPE to reduce exposures

S01.01A. Addressing Complex Local and Global Issues in Environmental Exposure and Health: Addressing the Health of Children and Adolescents

**S01.01.01. Early exposure to environmental pollutants and weight gain in children. Rio de Janeiro city / Brazil**

Ana Oliveira

*Ana N. Oliveira<sup>1</sup>, Carmen F. Asmus<sup>1</sup>, Nataly D. de Figueiredo<sup>1</sup>, Monica Seefelder<sup>1</sup>, Thatiana Fernandes<sup>1</sup>*

*1. Public Health Institute (IESC), Federal University of Rio de Janeiro (UFRJ), Rio de Janeiro, Rio de Janeiro, Brazil.*

**Abstract:** Background/Aim: In utero and early postnatal environmental pollutants exposures, can change the metabolism, predisposing individuals to the development of chronic diseases later in life. To evaluate prenatal exposure and to test viability for a birth cohort study, a pilot study was conducted in newborns at the School Maternity of the Federal University of Rio de Janeiro (ME-UFRJ), from October 2017 until August 2018, aiming to evaluate the exposure to the following environmental pollutants: metals, pyrethroids, organochlorines and organophosphates and plasticizers to investigate exposure to environmental pollutants and weight gain in children during the first six months of life. Methodology: The study was attended by 142 pregnant from Rio de Janeiro city, with delivery at ME-UFRJ. Interviews with exposure data and measurements on maternal samples of blood, urine and hair in the third trimester of gestation were performed, and umbilical cord and urine samples were collected from the newborns. In the follow-up of infants in the first, third and sixth month, neuropsychomotor and cognitive development assessments are performed through the Denver Developmental Screening Test, anthropometric measures and breast milk and baby's urine collected. After laboratory analysis, maternal and child exposure data will be checked, and statistical tests applied. The descriptive analysis of the data will be obtained from simple frequencies, measures of central tendency and variability. Multiple analysis techniques will be used according to the outcomes and exposures, using logistic regression for binary outcomes. Expected results Changes in the developmental patterns of children at birth and up to 6 months of age, represented by impairment of weight and height growth. Conclusions: To date we do not have the laboratory results to correlate with clinical findings. However, clinical exams point in the direction of subtle changes, requiring laboratory data to associate with these findings.

**S01.01.02. Analyze Health Data of Children and Adolescents in the Municipalities with the Highest Consumption of Pesticides in the State of Sao Paulo - Brazil (2000-2015)**

Abstract: Brazil has been the largest consumer of pesticides in the world since 2008. The state of São Paulo, with 645 municipalities and a population of 44 million people stands out as a major consumer. This study presents data on health problems, according to the Ministry of Health (Datasus), of the children and adolescents of the 15 municipalities that use pesticides the most, analyzing the characteristics of pesticides used. The data used are those available at the environmental health observatory and atlases of the geography of agrochemicals in Brazil.

### **S01.01.03. Characteristics of Health and Environment in Santa Gertrudes City: Sao Paulo, Brazil**

Abstract: City with higher levels of environmental pollution in Brazil. Presentation of the main characteristics of health and levels of air pollution in the last 10 years, considering data from the Ministry of Health and the environmental sanitation company. Reviews are made considering the health framework of children up to 15 years of age.

#### **S01.01.04. Birth Cohort Study of Environmental Exposure and Childhood Development: Rio de Janeiro / Brazil**

Carmen Asmus

*Carmen F. Asmus<sup>1</sup>, Monica Seefelder<sup>1</sup>, Nataly D. de Figueiredo<sup>1</sup>, Ana Paula Natividade<sup>1</sup>, Thatiana Fernandes<sup>1</sup>*

*1. Public Health Institute, Federal University of Rio de Janeiro, Rio de Janeiro, RJ, Brazil.*

**Abstract:** This study aims to investigate alterations in childhood development associated to exposure to environmental pollutants, from pregnancy until the age of 4. Its core hypotheses are: 1) the exposure to environmental chemical pollutants determines fetus developmental alterations, birth adverse health effects, and child's neuromotor and cognitive development deficits; 2) these effects of environmental pollutants are modulated by interaction with the sociocultural environment and genetic patterns; and 3) the exposure to violence, as a chronic stressor, alters the susceptibility to the environmental chemical pollutants effects on children's health. **Methodology:** This is a prospective cohort study whose study population will be all children born at the Federal University of Rio de Janeiro Birthing Center (ME-UFRJ), from March 1st, 2019 to February 29th, 2020. All newborns will be followed for 48 months and their landmarks of physical, neurological, psychological, and cognitive development recorded. The study protocol includes interviews, physical exams, and collection of biological samples at the 7th month of pregnancy, birth, and postnatal period until the age of 4. The study will collect: 1) socioeconomic, cultural, leisure and living conditions of the parents 2) Maternal biological samples (blood, urine and hair) 3) Cord blood and urine of the newborn. The Birthing Center performs 2,000 to 2,500 deliveries/year. **Results:** From October 2017 until July 2018, a pilot study has been done. Of 209 pregnant women attended at ME-UFRJ during the period of 2 months, 142 (67,9%) accepted to participate. Until this date, there were 131 births (92.3%), and cord blood was collected from 122 births (85.9%). **Conclusion:** This study may contribute to the increase of knowledge regarding the effects of environmental pollutants exposure, and its predisposing factors or conditions, on newborn and children's health in an urban area in Brazil.

## S01.01B Air Pollution and Physical Activity: Environmental Health Perspective

### **S01.01.05. Air Pollution and Physical Activity Epidemiology: Are Long-Term Benefits of Physical Activity on Health Modified by Exposure to Air Pollution?**

Zorana Andersen

Zorana J. Andersen<sup>1</sup>, Nadine J. Kubesch<sup>1</sup>, Jack Fisher<sup>1</sup>, Mark Nieuwenhuijsen<sup>2</sup>

1. Public Health, University of Copenhagen, Copenhagen, Denmark.

2. ISGlobal, Barcelona, Spain.

**Abstract:** Introduction: Physical activity amplifies respiratory uptake and deposition of air pollutants in the lung, which may augment acute harmful effects of air pollution during exercise. We aimed to examine whether long-term benefits of physical activity on morbidity and mortality are moderated by long-term exposure to air pollution levels in an urban setting. Methods: 57,000 subjects (50-65 years) from the Danish Diet, Cancer, and Health cohort, were recruited in Aarhus and Copenhagen between 1993 and 1999, when they reported data on leisure-time and utilitarian physical activity. We linked the cohort to Danish nationwide registers to extract data on overall- and cause-specific mortality, incidence of asthma and chronic obstructive pulmonary disease (COPD), and incidence of myocardial infarction (MI) and stroke. We used modeled NO<sub>2</sub> levels (high/medium/low) at the residence at the cohort baseline year as proxy for air pollution exposure during physical activity. We modeled association of participation in sports, cycling, gardening, and walking with the above mentioned health outcomes by Cox regression, and introduced NO<sub>2</sub> (low/medium/high) as an interaction term. Results: Of ca. 53,000 subjects, 5,534 died until 2010, 1,151 developed asthma and 3,225 COPD until 2013, 2,936 developed MI and 4,353 stroke until 2015. Participation in sports, cycling, walking and gardening was associated with reduced risk of premature mortality (18-22%), as well as with incident asthma (15-18%), COPD (15-19%), MI (9-15%), and stroke (10-18%), and these were not modified by NO<sub>2</sub>. Conclusions: Increased exposure to air pollution during exercise in urban setting does not outweigh beneficial effects of physical activity on the risk of premature mortality, respiratory and cardiovascular morbidity.

## **S01.01.06. Air Pollution and Physical Activity (APPA): Air Pollution Exposure in Travel Modes**

Juan Orjuela

*Juan P. Orjuela<sup>1</sup>, George Northover<sup>2</sup>, Shahram Heydari<sup>1</sup>, Audrey de Nazelle<sup>1</sup>*

*1. Centre for Environmental Policy (CEP), Imperial College London, London, United Kingdom.*

*2. Royal School of Mines, Imperial College London, London, United Kingdom.*

**Abstract:** Introduction Travel microenvironments are often the most polluted places people encounter in their daily lives. Encouraging walking and cycling may increase physical activity in the population, but also lead to higher intakes of pollutants (due to high inhalations rates in highly contaminated environments). Quantification of exposure contrasts between travel modes is needed to estimate potential risks and benefits of walking/cycling. Method A systematic review of global literature comparing exposures while walking and cycling to other modes (car, bus, overground/underground rail) was conducted. Data from the disparate set of studies was harmonized to estimate ratios of concentrations in active travel vs motorized travel modes for fine particulate matter (PM<sub>2.5</sub>), ultrafine particles (UFP), black carbon (BC) and carbon monoxide (CO). Comparisons were made for ratios obtained in different continents. Results Of 280 articles examined, 27 responding to inclusion criteria were retained for analyses. Most were derived from European studies although all continents except Antarctica were represented. Globally, walking was amongst the least exposed travel modes for BC and CO, with more inconsistent results for PM<sub>2.5</sub> and UFP. Cycling was amongst the most exposed for UFP, and the least exposed for BC (other than walking). Results varied by continent. Conclusion A large variety of study designs and settings makes a unified picture of air pollution contrasts between travel modes difficult. Nevertheless the ratios and associated confidence intervals obtained provide useful metrics for health impact modelling, enabling a comprehensive analysis of risk and benefit tradeoffs of walking and cycling policies in urban environments.

### **S01.01.07. Should You Avoid Cycling and Walking in High Pollution Days?**

Marko Tainio

*Marko Tainio<sup>1</sup>, Giorgos Giallourous<sup>2</sup>, Panayiotis Kouis<sup>2</sup>, Stefania Papatheodorou<sup>2</sup>, James Woodcock<sup>1</sup>*

*1. MRC Epidemiology unit, University of Cambridge, Cambridge, United Kingdom.*

*2. Cyprus International Institute for Environmental & Public Health, Limassol, Cyprus.*

**Abstract:** Background: Regular active commuting, such as cycling and walking to and from workplace, is associated with reduced all-cause mortality through increased physical activity (PA). However, active commuting may increase intake of fine particles (PM<sub>2.5</sub>), causing negative health effects. In this study we estimate the combined risk of PA and PM<sub>2.5</sub> for all-cause mortality among active commuters who, in days with high PM<sub>2.5</sub> levels work from home. Method: We modelled the changes in all-cause mortality by combining risks (exposure to PM<sub>2.5</sub> air pollution) and benefits (PA) for six cities (Helsinki, London, Sao Paulo, Warsaw, Beijing, New Delhi) using daily PM<sub>2.5</sub> concentrations as an input. In each day with PM<sub>2.5</sub> concentration above the threshold current active travellers were assumed to stay home. For threshold we used values 25 µg/m<sup>3</sup>, 50 µg/m<sup>3</sup>, 100 µg/m<sup>3</sup> and 150 µg/m<sup>3</sup> to examine which threshold value provides largest health benefits. The changes in PA and exposure to PM<sub>2.5</sub> in each city with each threshold value were estimated for three different calendar years. Results: Everyday cycling to work resulted in RRs from 0.80 (cycling) and 0.84 (walking) in Helsinki (lowest air pollution levels) to 0.86 (cycling) and 0.88 (walking) in New Delhi (highest air pollution levels). Restricting active commuting in high PM<sub>2.5</sub> days would not improve health in any examined city, but it could reduce health benefits in high air pollution cities (Beijing, New Delhi) if threshold value is below 150 µg/m<sup>3</sup>. Conclusions: Switching to working from home on in days with high air pollution would not lead to any health benefits in any examined city.

## **S01.01.08. Air Pollution, Physical Activity and Health: What Are the Pathways to Healthy Urban Living?**

Mark Nieuwenhuijsen

*Mark Nieuwenhuijsen<sup>1</sup>*

*1. ISGlobal, Barcelona, Spain.*

**Abstract:** Background and aims: Many cities still suffer from high air pollution and many citizens do not do enough physical activity. Physical activity should be promoted by including it into daily lives e.g. through active commuting. Concerns have been raised about the possible risks of being physically active when air pollutions are high. The aim of this presentation is to provide a rapid update on the current status of air pollution, physical activity and health while commuting and suggests solutions to improve the current situation. Method: We conducted a rapid review of the literature on of air pollution, physical activity and health while commuting and suggestions for potential solutions. Results: The presentation will provide a brief overview of the current status on the relationship and interaction of physical activity, air pollution and urban health using a couple of examples of epidemiological and health impact assessment studies, and provide some indications for future research in the area. Initially results suggest that the benefits of physical activity well outweigh the risk of air pollution, but that under some circumstances the full benefits of physical activity are not achieved when air pollution levels are high. It will provide recommendations how to improve urban and transport planning in the light of our current knowledge to promote healthy urban living e.g. through a reduction of car use, increase in active and public transport, greening of cities or a combination of these. Conclusion: healthy urban living can be promoted through an increase in physical activity and reduction in air pollution e.g. through a reduction of car use, increase in active and public transport, greening of cities or a combination of these

## S01.01C. Air Pollution Exposure and Metabolomics

### S01.01.09. Metabolomics Profiling in Response to Air Pollution Levels

Lina Mu

*Lina Mu<sup>1</sup>, Rachael Blair<sup>2</sup>, Richard Browne<sup>2</sup>, Han Yu<sup>2</sup>, Matthew Bonner<sup>1</sup>, Zhongzheng Niu<sup>1</sup>, Furong Deng<sup>3</sup>*

- 2. University at Buffalo, Buffalo, NY, United States.*
- 3. Peking University, Beijing, China.*

**Abstract:** Background: Metabolomics is a powerful tool in identifying metabolites and related pathways response to environmental stress, including air pollution. Epidemiological studies are limited so far. The study aims to identify metabolomics profile in response to air pollution exposure. Methods: We used 54 participants from an existing panel study in which serum from each participant was repeatedly collected before-, during-, and after- the 2008 Beijing Olympic Games when air pollution levels changed drastically. Ultra high-performance liquid chromatography/tandem accurate mass spectrometry (UPLC/MS/MS) was used in untargeted analysis. ANOVA was performed for each of the metabolites to compare their levels at three time points individually. The p-values were adjusted to control false discover rate at 0.05. Cluster analysis via graph partitioning was used to identify modules of metabolites that are regulated in a concerted manner, and investigate for over-represented pathways. Results: Totally 83 metabolites showed significant response among non-smokers after adjustment on individual metabolites analysis. Twenty modules were identified, among which the few largest modules represent pathways of fatty acids, lipid metabolism and peptides/amino-acids. Enrichment testing identified sub-pathways including Fatty Acid Metabolism (Acyl Carnitine), Gamma-glutamyl Amino Acid, Methionine, Cysteine, SAM and Taurine Metabolism, Glutathione Metabolism, Eicosanoid, Fatty Acid, Amino, Purine Metabolism, (Hypo)Xanthine/ Inosine containing, Leucine, Isoleucine and Valine Metabolism. Among smokers, 142 metabolites showed significant response to the changes of air pollution level, with larger observed changes than non-smokers. Module analysis suggested very similar pathways to that among non-smokers. Conclusion: Both smokers and non-smokers showed significant response to the changes in air pollution levels, especially in the pathways of fatty acids, lipid metabolism and peptides/amino-acids.

## **S01.01.10. Non-Targeted Metabolite Profiling of Dried Blood Spots in a Field-Based Epidemiologic Study of Household Air Pollution**

Abstract: Household air pollution (HAP), primarily from solid fuel combustion in cookstoves, is a leading risk factor for the global burden of disease; however, direct evidence linking HAP with chronic disease endpoints is limited. Obtaining clinical chronic disease measures in rural settings of low- and middle-income countries is logistically challenging; consequently, focus has been placed on subclinical indicators of risk. The ability to conduct non-targeted metabolomics profiling from dried blood spots (DBS) represents an innovative approach with potential for biomarker discovery and characterization. We conducted a cross-sectional study among 107 women, aged 25-55 years, using wood-burning cookstoves in rural Honduras. Kitchen and personal 24-hour fine particulate matter (PM<sub>2.5</sub>) concentrations were collected via gravimetric sampling. DBS were collected via finger-stick. Global non-targeted metabolite profiling was performed using reverse phase ultra performance liquid chromatography and high resolution mass spectrometry. In separate linear models, we evaluated the association between 24-hour PM<sub>2.5</sub> concentration and each metabolite, adjusting for age, body mass index, physical activity, and socio-economic status, using a correction for multiple testing. PM<sub>2.5</sub> exposures were associated with 27 out of 1,395 metabolites; five metabolites were annotated (e.g., phenylalanine, terpene). Lysophosphatidylcholine 18:2, a metabolite previously identified as being protective for incident coronary heart disease, was inversely associated with kitchen PM<sub>2.5</sub> concentrations. We will evaluate standards for annotated metabolites to quantify the PM<sub>2.5</sub> relationships. The use of DBS could have far-reaching impacts on field-based sciences, such as HAP research, by expanding the ability to characterize environmental impacts on metabolomic profiles in rural populations where relevant measurements were previously not feasible.

### **S01.01.11. Ambient Air Pollution Exposure Is Changing Metabolomics Profiles: A Link to Disease Development**

Cavin Ward-Caviness

*Annette Peters<sup>1</sup>, Cavin Ward-Caviness<sup>2</sup>, Susanne Breitner<sup>1</sup>*

*1. Helmholtz Zentrum München, Neuherberg, Germany.*

*2. Environmental Protection Agency, Chapel Hill, NC, United States.*

Abstract: Metabolomics offers an unbiased approach to characterize the metabolism and organ cross talk based on serum or plasma samples. It is potentially able to demonstrate systemic impacts of environmental exposures such as ambient air pollution beyond the lung. The presentation will discuss analyses linking ambient air pollution to changes in metabolomics profiles. It will consider both short-term and long-term exposures to ambient air pollution. It will further discuss the need for additional data analyses tools to capture fully the potential of the high-dimensional data. It will consider the challenges associated with measurement errors and intra-individual variability. Finally, the potential to unravel pathways linking ambient air pollution to the development and exacerbation of disease will be discussed.

## **S01.01.12. Module Detection in Attributed Networks for the Association with Outcomes**

Rachael Blair

*Rachael Blair<sup>1</sup>*

*1. Biostatistics, University at Buffalo, Buffalo, NY, United States.*

Abstract: Networks are widely used to model associations, direct and indirect relationships between a complex set of variables. Mining networks for modules/clusters of nodes (e.g., patients or samples) is an open and challenging problem. This problem is referred to as module (community) detection. The majority of approaches to the rely solely on the network structure. However, in biological networks, it is often the case that the nodes in a network have attributes (aka metadata) associated with them. Utilizing attribute information for the detection of communities is important to fully leverage the data but requires bridging the structural network with attribute data. In this talk, I will introduce the module detection problem in networks with complex attributes, and how to link these modules with outcome variables (e.g., exposure or survival) for prioritization. A novel method the Weighted Fast Greedy (WFG) algorithm will be introduced for attribute-based community detection that addresses this challenge in a scalable manner. WFG leverages logistic regression modeling and is used to bridge the structural and attribute spaces by regressing vectorized attribute similarities on the structural data. In this setting, weights are estimated that naturally emphasize (or dampen) attributes that associate with structure. WFG couples these weights with an existing fast greedy algorithm designed for large networks. The model also allows for mixed attributes and enables the prioritization of inferred modules through coefficient ranking, which directly captures attribute homogeneity. WFG shows good performance over a range of simulations for networks with varying levels of structure, in networks with missing links, and in networks where the community sizes are severely unbalanced. Examples will be presented that highlight applications in proteomics, metabolomics and transcriptomics.

## S01.01D. Bronchiolar and Interstitial Lung Disease by Occupational and Environmental Exposure: Their Implication and Future Task to Be Solved for Health Protection

### **S01.01.13. Outbreaks of Severe Lung Injury Caused by Agents that Were Deemed Safe: From Air-Sprayed Paints to Humidifier Disinfectants**

Benoit Nemery

*Benoit Nemery*<sup>1</sup>

*1. Public Health and Primary Care, KU Leuven, Leuven, Belgium.*

Abstract: In 1992, outbreaks of severe organizing pneumonia occurred in Spain among textile workers who had been air-spraying supposedly non-toxic paints (Moya et al. Lancet 1994, 344, 498-502; Romero et al. Eur Respir J 1998, 11, 265-71). The disease was named "Ardystil syndrome" after the factory where most casualties occurred. A smaller outbreak was caused by the same products in Algeria (Ould Kadi et al. Lancet 1994, 343, 962-3; Eur Respir J 1999, 13, 940-1). Experimental studies in vivo and in vitro demonstrated that the incriminated paints (Acramin FWR and Acramin FWN) were highly toxic for the respiratory tract (Clottens et al. Occup Environ Med 1997, 54, 376-87; Hoet et al. Toxicol Sci 1999, 52, 209-216), probably on account of their polycationic character (Hoet et al. Toxicol Appl Pharmacol 2001, 175, 184-190). The outbreaks of severe interstitial lung disease that occurred during spring among children and adults in South Korea between 2006 and 2011 were attributed to disinfectants added to domestic humidifier systems. The biocide that has been most consistently associated with the disease is polyhexamethyleneguanidine (PHMG), a polycationic agent of low oral or dermal toxicity, with structural similarity to the polycationic paints that caused the Ardystil syndrome (Nemery and Hoet. Am J Respir Crit Care Med 2015, 191, 116-7). PHMG eventually also proved to exhibit high respiratory toxicity in experimental animals and in vitro test systems. Several other examples exist of serious respiratory disease caused by chronic inhalation of supposedly safe agents (butter flavour, nylon microfibres) for which toxicity by inhalation was only demonstrated experimentally many years after epidemiological studies had shown that they could cause lung injury in humans. Potentially inhaled agents must be deemed hazardous until proven innocent.

#### **S01.01.14. Bronchiolar and Interstitial Lung Disease by Humidifier Disinfectant Syndrome in Korea**

Jong Han Leem

*Jong Han Leem*<sup>1</sup>

*1. Occupational and Environmental Medicine , Inha University, Incheon, Korea (the Republic of).*

Abstract: The outbreaks of severe interstitial lung disease that occurred during spring among children and adults in South Korea between 1994 and 2011 were attributed to disinfectants such as polyhexamethyleneguanidine (PHMG), added to domestic humidifier systems. Several papers reported that these interstitial lung diseases have the following characteristics: nonsuppurative necrotizing and obliterative bronchiolitis with various stages of peribronchiolar organizing alveolar damage, Relative sparing of subpleural and paraseptal parenchyma. But following studies showed many other interstitial pneumonitis are also associated with the exposure of humidifier disinfectants by big data analysis. Our studies showed that there are clear dose-response relationships between many other interstitial pneumonitis and the exposure of humidifier disinfectants in humidifier disinfectants victims and some general groups. Different exposure patterns and underlying diseases made diverse types of bronchiolar and interstitial lung disease. What is toxicologic mechanism of humidifier disinfectants? ROS (Reactive Oxygen Species), decreased T cell and pro-inflammatory cytokine release from macrophage could raise the possibilities of causing interstitial fibrosis, asthma and many other diseases. . All adverse health effects byhumidifier disinfectants can be called as humidifier disinfectants syndrome. Our survey also showed that the magnitude potential victims with adverse effects from humidifier disinfectants are from two million to 0.4 million. We only found the tip of an iceberg about the humidifier disinfectants syndrome. We can explore the real adverse outcomes by epidemiologic study using big data such as National Health Insurance Data and toxicologic studies. Toxicokinetic studies will support the results of toxicologic studies such as in-vitro, in vivo, adverse outcome pathways (AOPs) studies.

### **S01.01.15. Health Damage of Humidifier Disinfectant by Big Data Analysis in Korea**

Hae-Kwan Cheong

*Jaiyong Kim<sup>2</sup>, Hae-Kwan Cheong<sup>3</sup>, Jong Han Leem<sup>1</sup>*

- 1. Occupational and Environmental Medicine , Inha University, Incheon, Korea (the Republic of).*
- 2. Health and Society Institute, Hanyang University , Seoul,, Korea (the Republic of).*
- 3. Social and Preventive Medicine, Sungkyunkwan University, Seoul, Korea (the Republic of).*

Abstract: The accident of humidifier disinfectants found in 2011 was one of the biggest man-made environmental disaster in South Korea. It was estimated that at least 5 million people was exposed and 5 hundreds of thousands people experienced health problems. However, the governmental countermeasures focused mainly on the differential diagnosis and compensations for the voluntary registered victims of 6,000 people. So, the epidemiologic studies to uncover the size of health problems were insufficient. We tried to estimate the correlation between humidifier disinfectants consumption with some target diseases (interstitial pulmonary diseases, asthma, etc.) in South Korea using the National Health Insurance Research Database Study. Claims data of 50 million people over 15 years (January 2002~September 2017) were reconstructed to extract episodes of care with target diseases diagnosis including residence district and SES. Relative risk estimates from age-period-cohort and difference in difference analysis were compared with humidifier disinfectant consumptions (1994~2011). In 282,114 interstitial pulmonary diseases patients, correlation coefficients between relative risk estimates of 'period effect' and humidifier disinfectant consumption were 0.942 in male and 0.930 in female with 1 year latent period assumption. Correlation coefficients between relative risk estimates of 'cohort effect' and humidifier disinfectant consumption were 0.854 in male and 0.797 in female. And, we found a specific rise and fall pattern among 2003~2011 birth cohorts. We could find high correlation and specific rise & fall patterns of health care episodes with humidifier disinfectant consumption using national total population cohort data. These kinds of big data system can make relatively objective epidemiologic evidences for environmental health problems.

### **S01.01.16. Characteristics of Exposure to Humidifier Disinfectant (HD) among Patients with Lung Injury**

Dong-Uk Park

*Dong-uk Park<sup>2</sup>, Jong Han Leem<sup>1</sup>*

*1. Occupational and Environmental Medicine , Inha University, Incheon, Korea (the Republic of).*

*2. Department of Environmental Health, Korea National Open University, Seoul, Korea (the Republic of).*

Abstract: Since around the year 2000, hundreds of people in Korea have developed humidifier disinfectant associated lung injury (HDLI). We evaluated the association of HD use with LI among the 1,199 people who had registered with the Humidifier-associated with Lung Injury Investigation and Decision Committee (HLI IDC) up to the third round. Through clinical examinations by a team consisting of pediatric pulmonologists, radiologists, and pathologists, the level of association of lung injury with the use of HD was sorted into definite, probable, possible, and unlikely. Lung injury patients with an association with the use of HD ranked as possible and higher were all categorized as HDLI patient groups. Among the registered people, 38% (1st round=214, 2nd =73, 3rd=166) were confirmed as HDLI patients. Children aged under eight years old made up the highest proportion of HDLI cases (n=279, 62%), followed by pregnant women (n=31, 7%). One hundred thirty (29%) of the HDLI patients died. Fifty-seven percent of HDLI patients (n=259) developed HDLI after less than one year of HD use. The number of HDLI patients who used only the Oxy Saksak HD brand was found to be 176 (39%), followed by the brands Cefu (n=27, 6%). HD products containing only PHMG were the most frequently used among HDLI patients (n= 234, 52%), followed by PGH (n=27, 6%) and a mixture of CMIT and MIT (n=26, 6%). In conclusion, the development of HDLI was evaluated to be associated with the use of 11 HD products containing PHMG, PGH, and CMIT/MIT.

## S01.01E. Climate, Air Pollution, and Environmental Health in Africa 1

### S01.01.17. Short Term Seasonal Effect of Ambient Air Pollutants and Airborne Fungal Spores on the Lung Function of School Children in Western Cape, South Africa: A Panel Study

Toyib Olaniyan

*Toyib Olaniyan<sup>1</sup>, Mohamed Jeebhay<sup>1</sup>, Martin Rössli<sup>2</sup>, Rajen Naidoo<sup>3</sup>, Nino Küenzi<sup>2</sup>, Kees de Hoogh<sup>2</sup>, Dilys Berman<sup>1</sup>, Bhawoodien Parker<sup>4</sup>, Joy Leaner<sup>4</sup>, Mohamed A. Dalvie<sup>1</sup>*

*1. Public Health, University of Cape Town, Cape Town, South Africa.*

*2. Swiss Tropical and Public Health Institute, Basel, Switzerland.*

*3. University of KwaZulu-Natal, Durban, South Africa.*

*4. Department of Environmental Affairs and Developmental Planning, Cape Town, Western Cape, South Africa.*

**Abstract:** Background: Only 3 previous epidemiological studies have investigated the combined effect of short-term ambient air pollutants and fungal spores on individual level children's lung function. These studies did not investigate respiratory effects beyond 1-day lag nor investigated interaction effects. We aimed at investigating the combined effect of short-term air pollutant and fungal spore exposure on individual level lung function of school children. Methods: A panel study was conducted incorporating testing for 2 consecutive school-weeks each in summer and winter on 553 grade-4 school children from 4 informal settlements in the Western Cape Province of South Africa. Outcomes were measured using peak flow meters obtained 3-times daily concurrently at all schools. Daily PM10 levels was available from a stationary monitor near 2 of the study areas, while daily levels of fungal spores was measured using spore traps in all 4 study areas throughout the year. The effects were analysed using single- and multi-pollutant distributed lag linear and non-linear model for lags up to 5-days. Results: Daily *Alternaria* and *Cladosporium* was significantly associated with FEV1 deficit and increased PEF intraday variability, especially in winter. The strongest adverse effect was on FEV1 (-369.34 ml, 95% CI: -650 to -87.77 ml) resulting from an overall cumulative increase of 50 spores/m<sup>3</sup> in *Cladosporium* from lag day-0 through lag day-5. There was significant interaction between PM10 and *Alternaria* on reduced FEV1 ( $p < 0.001$ ) and increased intraday-variability in PEF ( $p < 0.001$ ), including PM10 - *Cladosporium* interaction on increased intraday variability in PEF ( $p < 0.01$ ), all during winter. Conclusion: The study provides evidence that daily exposure to ambient fungal spores, *Alternaria* and *Cladosporium* results in lung function deficits especially in winter. The adverse effect on lung function by the fungal spores can occur beyond the day of exposure and is modified by ambient PM10 exposure.

## **S01.01.18. Closing Research Gap on Climate Change and Health in Africa**

Adetoun Mustapha

*Adetoun Mustapha<sup>1</sup>*

*1. Epidemiology and Biostatistics, MRC-HPA Centre for Environment and Health , Imperial College London, Lagos, Nigeria.*

Abstract: The effects of climate change are felt in many parts of Africa with the alteration of intensity and seasonal nature of the rains; elevation of average annual temperatures; and increased frequency of high impact weather phenomena including drought and flooding. The resulting health risks will particularly affect vulnerable and poorly resourced populations. A review of literature was conducted on Google Scholar to explore research available on awareness of climate change among populations that depends on climate sensitive resources for livelihood in Africa and effectiveness of adaptive measures on public health at regional level. The search was carried out on 28 March 2018 and limited to articles that were published in English Language since 2008. Additionally, the reference lists of relevant articles were manually checked. Some 20,100 records were retrieved, out of which 120 full papers were assessed and 21 reviewed. The number of published literature retrieved for the whole of the African continent is about the same for developed countries like United Kingdom and United States of America. There were more studies on vulnerability assessments of natural environment than awareness of climate change by socioeconomically disadvantaged populations and effectiveness of adaptive interventions on public health. Research are primarily being driven by international institutions, national governments, NGOs and were mainly from those nations receiving adaptation funds. There is minimal involvement of lower levels of government and local academic institutions or collaboration across nations or African professionals. Gaps in knowledge of effective local adaptation actions and adaptation policy are particularly notable. Future research needs to address these gaps through regional collaboration and involvement of local institutions and network of African researchers to be able to promote proactive adaptation actions that is beneficial to public health at regional level.

## **S01.01.19. No More Disciplinary Silos in Tackling Climate Change Impact on Health: Lessons from an Ecohealth Research Project in West Africa**

Brama Kone

*Brama Kone<sup>1</sup>, Mouhamadou S. Chouaibou<sup>2</sup>, Sid'Ahmed Dahdi<sup>3</sup>, Kristie L. Ebi<sup>4</sup>, Gueladio Cisse<sup>5</sup>*

*1. Centre Suisse de Recherches Scientifiques en Côte d'Ivoire & University Péléforo Gon Coulibaly of Korhogo, Abidjan 01, Abidjan, Côte d'Ivoire.*

*2. Centre Suisse de Recherches Scientifiques en Côte d'Ivoire, Abidjan, Abidjan 01, Côte d'Ivoire.*

*3. University of Sciences and Technologies of Medicine, Nouakchott, Mauritania.*

*5. Swiss Tropical and Public Health Institute and University of Basel, Basel, Switzerland.*

Abstract: Vector-borne diseases contribute significantly to the burden of disease in Africa and climate changes is adding new pressures. However, the complex impacts in terms of related hazards, vulnerabilities and exposure are not adequately understood. We used an Ecohealth research methodology to develop community-based interventions against malaria and schistosomiasis in Korhogo and Kaédi, two west African cities. We collected field data during rainy and dry season on each site by cross-sectional surveys: household questionnaire and parasitological surveys, entomological, malacological and geographical survey. In addition, weather and climate data have been generated. In Korhogo, malaria prevalence was 17 % (583/3422) and 8,1% (280/3446) during rainy and dry seasons respectively, while 0,07% (3/4297) and 0,6% (23/3863) during the same seasons in Kaédi. An increment in rainfall of 1 Cm during two month before was on average associated with a 1.0% (95%-CI: 0.4% to 1.6%) increase in malaria incidence in Korhogo. Anopheles larvae were 19,44% (3803/19560) and 0,3% (4/1056) of all larvae collected respectively in Korhogo and Kaedi. Dissolved oxygen (OR =1.20; p=0.029), Conductivity (OR =0.99; p=0.003) and Turbidity (OR = 0.99 ; p=0.007) have strong correlations with presence of Anopheles larvae in water bodies. Urinary schistosomiasis was more prevalent in Kaédi 3,44% (88/2554) than in Korhogo (0,4% (9/2373)) while Intestinal schistosomiasis was mainly observed in Korhogo (4,6% (102/2211)). Three snail species were collected in each site: *Bulinus truncatus*, and *B. forskalii* in both, *B. senegalensis* in Korhogo and *Biomphalaria pfeifferi* in Kaédi. There is a strong propensity to self-medication by the use of traditional plants. People practiced a care syncretism for malaria while for schistosomiasis, they mainly use local traditional strategies. Results were presented to all stakeholders and community-based interventions were implemented to face the two diseases.

## **S01.01.20. Evaluating the Effectiveness of a Community-Based Adaptation Strategy for Dengue Vector Control in Burkina Faso**

Tarik Benmarhnia

*Tarik Benmarhnia<sup>1</sup>, Samira Ouédraogo<sup>2</sup>, Valery Ridde<sup>3</sup>*

*1. Family Medicine and Public Health, UCSD, La Jolla, CA, United States.*

*2. EBOH, McGill University, Montreal, QC, Canada.*

*3. IRD, Paris, France.*

**Abstract:** Dengue outbreaks have occurred in several sub-Saharan African countries since 2010 and are expected to increase in the context of climate change. The success of efforts for prevention and control of dengue relies on the effectiveness of initiatives related to control of *Aedes* mosquito breeding sites, improving population mobilization, engagement knowledge, and improving household environmental sanitation, through sustained modification of human behavior. We developed and implemented an experiment for dengue vector control in Ouagadougou, the capital of Burkina Faso. Households in the intervention (n=287) and control (n=289) neighborhoods were randomly sampled and the outcomes collected before the intervention (October 2015) and afterwards (October 2016). The primary outcomes included: blood samples from residents to evaluate their exposure to *Aedes aegypti* (DV) bites and the density of pre-imaginal stages of the vector in water-holding containers. Data analysis included propensity score stratification approaches. The intervention reduced residents' exposure to DV bites (vector saliva biomarker difference= -0.08, 95% CI=-0.11; -0.04). The pupae index, a key entomological indicator for adult mosquitoes, declined in the intervention neighborhood (from 162.14 to 99.03) while it increased in the control (218.72 to 255.67). Well-planned, evidence-based community-based adaptation strategy for dengue vector control are feasible in West African urban settings and can be effective in controlling and reducing exposure to DV.

## S01.01F Complex Rural Exposures and Health

### **S01.01.21. Assessment of Exposure and Health Outcomes in Rural Settings**

Meghan Davis

*Meghan F. Davis<sup>1</sup>, Ana Rule<sup>1</sup>*

*1. Environmental Health and Engineering, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States.*

Abstract: Exposures to toxicants and infectious agents in rural settings often differ from those in urbanized areas, and the link between these complex exposures and health outcomes has been given less attention at both the research and the regulatory levels. The goals of this presentation, which will introduce and provide an overview of the "Complex Rural Exposures and Health" symposium, are to offer examples of why linkage of exposure and health in rural settings is important, discuss emergent tools and approaches for measurement of exposure, examine the challenges of both exposure and health outcome assessment in these settings, and discuss how interdisciplinary and multi-institutional efforts can be used to overcome these challenges. Examples will focus on measurement of biological exposures (pathogens, microbiome, allergens) and gases (ammonia, hydrogen sulfide). Quantitative (epidemiologic) methods, qualitative methods and One Health approaches will be offered. Engagement of stakeholders will be emphasized. Through this presentation, the symposium organizers will provide the unifying principles for the symposium and introduce formal methods that catalyze or support interdisciplinary approaches to link exposure assessment and health outcomes in rural settings.

## **S01.01.22. Object Based Image Analysis (OBIA) Methods for Mapping Poultry Farm Locations**

Beth Feingold

*Beth Feingold<sup>1</sup>, Sean MacFaden<sup>2</sup>, Dylan Nagy<sup>1</sup>, Jarlath O'Neill-Dunne<sup>2</sup>*

*1. School of Public Health, University at Albany, State University of New York, Rensselaer, NY, United States.*

*2. Spatial Analysis Lab, University of Vermont, Burlington, VT, United States.*

**Abstract:** Background: Livestock production is a major industry in the United States. Though livestock farms are associated with community exposures to pathogens and environmental pollutants, conducting exposure assessments and epidemiological analyses are often hindered by the difficulty of ascertaining their geographic locations. While county and watershed level counts of animal operations are available through the US Department of Agriculture's Agricultural Census, a publicly available dataset of livestock farm locations does not exist. Objective: The presentation will explore a novel method employing object based image analysis (OBIA) to map farm locations, highlighting a case study of poultry farms in the state of Delaware (DE), USA. Methods: Briefly, a rule-based expert system to identify poultry houses was designed in eCognition Developer and deployed using eCognition Server (Trimble, Inc. Westminster, CO) that employs OBIA techniques to conduct a feature extraction of poultry farms from a combination of high-resolution imagery, LIDAR (light detection and ranging), and ancillary vector datasets, yielding a proposed geospatial database of poultry farm locations. Results were imported into ArcGIS (ESRI Corp, Redlands, CA) for subsequent analysis. Accuracy of poultry operation locations was assessed visually and in comparison to an animal operation facilities dataset from the DE's publicly available land use / land cover dataset and the Delaware Environmental Navigator. Results: Producer's accuracy for identifying poultry farms was 90%. While user's accuracy was 50%, this was improved significantly by utilizing ancillary datasets. 3% of operations identified as poultry operations were non-poultry animal operations. Conclusion: Object based image analysis, especially when used in conjunction with ancillary data, is a promising tool for mapping poultry operations. Further study is needed to determine its generalizability to other animal operation types and geographic areas.

### **S01.01.23. Electronic Health Records for Population Health Research in Rural Communities**

Joan Casey

*Joan A. Casey<sup>1</sup>*

*1. School of Public Health, UC Berkeley, Berkeley, CA, United States.*

Abstract: Most healthcare systems now use electronic health records (EHRs) to catalog clinical care and track patient health over time. EHR-derived data offers a unique and particularly useful resource for epidemiologists to study populations and individuals distributed across a range of environments. In contrast to classic cohort studies, usually deployed from urban centers, EHR databases provide a low-cost means of accessing rich longitudinal data on diverse populations in rural communities. Access to this data has allowed researchers to evaluate research questions of importance to rural communities, including potential associations between high-density livestock production and unconventional natural gas development and population health. Patient health data from Geisinger in Pennsylvania previously revealed associations between high-density poultry production and *Campylobacter* diarrheal infection and unconventional natural gas development and preterm birth. In fact, when stratifying analyses by community type (i.e., rural, suburban, and urban), associations between high-density poultry production and *Campylobacter* diarrheal infection strengthened. Using these two prior studies as scaffolding, this talk will provide an overview of the content and accessibility of EHR data. It will cover source population identification, cohort assembly, exposure assessment, how to extract health and social data from the EHR, and how to link these data with publicly-available data outside the EHR to better understand diseases in rural U.S. communities.

## **S01.01.24. Implementation of a Panel Exposure and Health Study in a Rural Setting**

Meredith McCormack

*Meredith McCormack<sup>1</sup>, Kirsten Koehler<sup>1</sup>, Nadia Hansel<sup>1</sup>, Phillip Scheuerman<sup>2</sup>, Ying Li<sup>2</sup>, Mildred Maisonet<sup>2</sup>*

*1. Medicine, Johns Hopkins University, Baltimore, MD, United States.*

*2. Epidemiology, East Tennessee State University, Johnson City, TN, United States.*

Abstract: Drivers of environmental health disparities may differ between urban, suburban, and rural regions. The CURE COPD Program focuses on environmental determinants of COPD with a goal of identifying approaches to reduce harmful exposures and improve health among those living in poverty with COPD in rural and urban settings. The CURE COPD Appalachia project is a collaboration between East Tennessee State University and Johns Hopkins University. Through this partnership, we have designed and implemented a longitudinal study focused on identifying sources of indoor air pollution and measuring the impact of exposure on respiratory morbidity in COPD. The study includes detailed home inspection and continuous air monitoring for one week at baseline, 3, and 6 months with simultaneous assessment of respiratory health outcomes. The successful implementation of this study has required that we address challenges through community engagement, intensive training of study staff, frequent communication between study teams, and with the assistance of community based champions of the project. We discuss lessons learned through our partnership and the conduct of this longitudinal environmental cohort study.

## S01.01G. Evaluating High-Throughput New Approach Methods (NAM) for Exposure

### S01.01.25. Evaluation of High-Throughput Chemical Functional Use Models

Katherine Phillips

*Katherine Phillips<sup>1</sup>, Kristin Isaacs<sup>1</sup>, Daniel Chang<sup>2</sup>, Kristan Markey<sup>3</sup>*

- 1. National Exposure Research Laboratory, US EPA, RTP, NC, United States.*
- 2. Office of Pollution Prevention and Toxics, US EPA, Washington, DC, United States.*
- 3. Office of Science Coordination and Policy, US EPA, Washington, DC, United States.*

Abstract: The United States Environmental Protection Agency's Office of Research and Development has generated high-throughput quantitative structure-use relationship (QSUR) models that predict the probability of a chemical fulfilling a specific functional use in consumer products and chemical processes, through knowledge of that chemical's structure. Identification of a chemical's functional use provides clues to both its expected concentration and the intentionality of its presence in a product. Information on the presence or amount of chemicals in products can be used as inputs to exposure models but is often lacking. For these data-poor chemicals, predictions of functional use can be used to parameterize high-throughput exposure models and support rapid prioritization of chemicals for risk and alternatives assessments. The QSUR models were built using a training set of functional use data derived primarily from the consumer product sector. Publicly available functional uses reported for chemicals in the industrial sector by manufacturers under the Chemical Data Reporting (CDR) Rule of the Toxic Substances Control Act were used to evaluate the QSUR model predictions for industrial chemicals. A total of 5153 chemicals in CDR had reported functional uses that could be compared to QSUR predictions. Only 2689 of these are single compounds with a definite, disclosed structure. Of those 2689, 1603 had predictions with a high probability ( $\geq 80\%$ ) of having a functional use and were within a model's domain of applicability. In addition, sector information (industrial or consumer) reported in the CDR was used to explore structural differences in chemicals having the same function in different sectors showing that chemicals with certain functional uses (solvents, preservatives) can differ drastically in structure from one sector to another, while others (emulsifiers, surfactants) can have similar structures in both sectors. This abstract does not necessarily reflect US EPA policy.

## **S01.01.26. Comparison of High-Throughput Exposure Predictions to Traditional Exposure Assessments under Canada's Chemicals Management Plan**

Angelika Zidek

*Angelika Zidek<sup>1</sup>*

*1. Health Canada, Ottawa, ON, Canada.*

Abstract: Under Canada's Chemicals Management Plan, over 3000 substances have been assessed and concluded on under the Canadian Environmental Protection Act (1999). As part of these conclusions, hundreds of assessments have been published over the last 10 years. These assessments include quantitative exposure estimates for the general population from a wide range of sources such as food, indoor and outdoor air, water, soil, dust as well as products available to consumers (e.g. cosmetics, textiles, paints, cleaners, toys). This presentation will compare results from high-throughput exposure models with exposure estimates from recently completed assessments under Canada's Chemical Management Plan. High-throughput exposure models such as SHEDS-HT will be compared to exposure estimates generated using 'traditional' exposure tools as well as available environmental monitoring and human biomonitoring data. The role of route as well as duration of exposure will also be discussed. This presentation will also look at drivers of exposure and risk, including the role of near and far-field exposures, as well as the relationship between types of product uses, and reported volumes for both human health risk assessment and chemical priority setting.

## **S01.01.27. Evaluating NAMs for Toxicokinetics**

John Wambaugh

*John Wambaugh<sup>1</sup>, Barbara A. Wetmore<sup>2</sup>, Robert G. Pearce<sup>1</sup>, Gregory S. Honda<sup>1</sup>, Risa R. Sayre<sup>1</sup>, Katie P. Friedman<sup>1</sup>, R. W. Setzer<sup>1</sup>, Russell S. Thomas<sup>1</sup>*

*1. National Center for Computational Toxicology, US Environmental Protection Agency, Research Triangle Park, NC, United States.*

*2. National Exposure Research Laboratory, US Environmental Protection Agency, Research Triangle Park, NC, United States.*

Abstract: Toxicokinetics (TK) is required information for chemical risk assessment. Unfortunately, TK data are not available for most chemicals in commerce and the environment. New approach methodologies (NAMs) have been developed to predict time course concentrations in relevant tissues or plasma based upon in vitro experimental data and physico-chemical properties. These high throughput TK (HTTK) data and models are made freely available through an add-on ("httk") to the free statistical software R as well as through the US EPA CompTox Chemistry Dashboard (<http://comptox.epa.gov>). Using HTTK, data from high throughput screening projects such as Tox21 and ToxCast can be compared to exposure estimates to generate risk-based prioritizations. HTTK NAMs are being evaluated through 1) uncertainty analysis and 2) comparison between in vitro predictions and in vivo measurements of both plasma concentrations and doses associated with the onset of effects (i.e., "points of departure"). Bayesian methods allow chemical-specific uncertainty estimates for in vitro TK data. Monte Carlo simulation can propagate both measurement uncertainty and biological variability into risk predictions, indicating that for most chemicals, variability contributes substantially more than uncertainty. Comparisons between in vitro predictions and in vivo observations have relied on two approaches: comparison between HTTK predicted time course concentrations in plasma and in vivo data indicate that some properties (e.g. average and maximum concentration) can be predicted with confidence. Second, comparison between in vitro bioactivity data and HTTK-adjusted internal dose predictions for in vivo points of departure has refined assumptions of the HTTK NAMs. NAMs for TK could allow risk-based prioritization of large numbers of chemicals. The views expressed here are those of the authors and do not necessarily reflect the views or policies of the U. S. EPA

## **S01.01.28. Evaluation of High-Throughput Chemical Exposure Models: Case Study of Matched Environmental and Biological Measurements**

Kristin Isaacs

*Kristin Isaacs<sup>1</sup>, R. W. Setzer<sup>1</sup>, Robin E. Dodson<sup>3</sup>, Ruthann Rudel<sup>3</sup>, Derya Biryol<sup>2</sup>, John Wambaugh<sup>1</sup>*

- 2. Oak Ridge Institute for Science and Education, Research Triangle Park, NC, United States.*
- 3. Silent Spring Institute, Boston, MA, United States.*

Abstract: U.S. EPA, under its ExpoCast program, is developing high-throughput near-field modeling methods to estimate chemical exposure and to provide real-world context to high-throughput screening (HTS) data. These novel modeling methods include reverse methods, which infer parent chemical exposures from biomonitoring measurements, and forward models to predict multi-pathway exposures from chemical use information and/or residential media concentrations. Both modeling methods were used to characterize the relationship between near-field environmental and biomarker measurements. Indoor air, house dust, and urine samples of 120 females (aged 60 to 80 years) were analyzed. In the measured data, 78% of the residential media measurements and 54% of the urine measurements were below the limit of quantification. Due to the degree of censoring in both air and dust data, we applied a latent variable estimation approach based on an expected relationship between air and dust concentrations. Using the partitioning model of Weschler and Nazaroff (Atmos. Env., 2010) and assumptions about the variance in concentrations within homes, we jointly estimated chemical-specific geometric mean air and dust concentrations from the observed measurements. This resulted in 14 chemicals with matched air, dust, and urine metabolite data. The indoor air and dust concentrations were compared to population median exposures inferred from urine metabolite concentrations using a reverse-dosimetry approach. Median air and dust concentrations were found to be correlated with inferred exposures; forward model predictions were used to characterize pathway contributions to aggregate exposures. These results demonstrate that the forward and reverse methods being developed in ExpoCast can predict intake amounts and routes of exposure, and that these models can also identify exposure pathways that contribute to biomarker concentrations in the general population. This abstract does not reflect EPA policy.

## S01.01H. Harmonization of Biomonitoring Measurements: Approaches Used by Laboratory Networks in Canada, Europe and the United States

### **S01.01.29. Harmonization of Biomonitoring Measurements in the Canadian Health Measures Survey: An Overview of Approaches, Challenges, and Successes**

Annie St-Amand

*Kathy Nguyen<sup>1</sup>, Julie Yome<sup>1</sup>, Ellen Lye<sup>1</sup>, Alain LeBlanc<sup>2</sup>, Audra Nagasawa<sup>3</sup>, Patrick Bélanger<sup>2</sup>, Ciprian-Mihai Cirtiu<sup>2</sup>, Eric Gaudreau<sup>2</sup>, Scott Mclean<sup>3</sup>, Annie St-Amand<sup>1</sup>*

- 3. Statistics Canada, Ottawa, ON, Canada.*

**Abstract:** The generation of high-quality biomonitoring data is essential for human exposure assessment and health effects research. The Canadian Health Measures Survey (CHMS) is the most comprehensive, direct health measures survey conducted in Canada and includes a biomonitoring component to measure exposure to environmental chemicals. Since its initiation in 2007, the program has successfully measured more than 250 chemicals in the blood, urine, and hair of Canadians. CHMS biomonitoring data have been used to establish baseline human biomonitoring concentrations in Canadians, inform public health, regulatory risk assessment and management decisions, and fulfill national and international chemical reporting requirements. These achievements required efforts to harmonize this program with other national and international programs on various areas of biomonitoring. This study provides an overview of the harmonization approaches in different practical aspects of the Canadian national biomonitoring program, including chemical selection, laboratory implementation and coordination (including method development, validation, and QA/QC processes), and data reporting (including LOD/LOQ and report format). Harmonization of approaches in Canada's program ensures consistency across programs, comparability of data from one cycle to the next and with other populations, and enables tracking of exposure over time. Continued coordination of approaches will provide opportunities for the development of a biomonitoring network to enhance collaboration and cooperation among national and international biomonitoring programs.

### **S01.01.30. Harmonization of Human Biomonitoring and Untargeted Exposure Analysis in Children's Health**

David Balshaw

*David M. Balshaw<sup>1</sup>*

*1. National Institutes of Environmental Health Sciences, Durham, NC, United States.*

Abstract: The NIEHS Children's Health Exposure Analysis Resource (CHEAR; <https://chearprogram.org/>) is a network of laboratories and a data analysis center providing harmonized analysis of environmental exposures in NIH studies focused on children's health. The Consortium provides three layers of analyses; traditional, hypothesis driven, biomonitoring; untargeted, discovery driven, Exposomics, and mechanistic anchoring through biological response indicator profiling. In an effort to ensure the highest quality of analyses and greatest comparability between laboratories CHEAR has implemented a hierarchy of strategies to standardize and harmonize the analyses. These include internal and external proficiency testing, common quality assurance standards and randomization schemes which will be discussed in detail. CHEAR has also undertaken a cross validation of targeted and untargeted methods to assess the reliability of untargeted methods as a tool for exposure assessment.

**S01.01.31. Harmonization of Human Biomonitoring Measurements in the National Biomonitoring Network (United States): Learning from the Experiences of Others**

Julianne Nassif

*Julianne Nassif<sup>1</sup>*

*1. Environmental Health, Association of Public Health Laboratories, Silver Spring, MD, United States.*

Abstract: The assessment of community environmental exposures, evaluation of public health interventions and the development of effective environmental health policy are all reliant on high quality biomonitoring data. The newly formed National Biomonitoring Network (NBN) aims to harmonize biomonitoring measurements determined in local, state and federal government laboratories with the goal of data comparability and sharing to inform public health practice. The NBN is a performance based network affording flexibility in the use of analytical methods and platforms but increasing the need for robust quality management programs and demonstrations of technical proficiency. By researching the approaches to measurement harmonization used in other biomonitoring networks and assessing the strengths and challenges presented by each, the NBN Steering Committee will refine the harmonization protocols developed for study design, specimen collection, analytical testing, data analysis and data management.

## **S01.01.32. Harmonization of Human Biomonitoring in Europe: The European Human Biomonitoring Initiative HBM4EU**

Marike Kolossa-Gehring

*Marike Kolossa-Gehring<sup>1</sup>, Ulrike Fiddicke<sup>1</sup>, Holger M. Koch<sup>2</sup>, Marta Esteban<sup>3</sup>, Argelia Castaño<sup>3</sup>*

*2. Institute for Prevention and Occupational Medicine of the German Social Accident Insurance, Institute of the Ruhr-Universität Bochum (IPA), Bochum, Germany.*

*3. Centro Nacional de Sanidad Ambiental (CNSA), Instituto de Salud Carlos III (ISCIII), Madrid, Spain.*

Abstract: HBM4EU follows an innovative approach to generate the knowledge policy makers need to improve policy in the field of environment and health. Successful chemical policy also relies on sound human biomonitoring data. At the European level data from different countries must be comparable between countries to be used for regulatory purposes at EU level and for elucidating potential regional differences. HBM4EU consists of 109 partner organisations from 28 countries -27 European countries plus Israel - and is organised around 16 work packages led by key players of national HBM studies and research programmes. Major fields of activities are the science policy transfer, Human Biomonitoring (HBM) studies, and research to elucidate the impact of exposure on health. HBM reveals extent and quality of multiple chemicals exposures. Harmonisation is needed at all phases of HBM studies: e.g. study design, data protection and ethical issues, study information materials, informed consent, field work, selection of appropriate biomarkers and matrices, comparability of chemical analysis, QA/QC programs, mixtures, novel biomarkers and screening approaches, sample storage and transport and data analysis. This project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 733032.

## S01.01I. Mobilizing Data for Healthy Environments: Platforms Facilitating Health and Environmental Exposure Linkage

### S01.01.33. Enhancing Environmental Data Resources in Cohort Studies: ALSPAC Exemplar (ERICA)

Andy Boyd

*Andy Boyd<sup>1</sup>, Anna Hansell<sup>2</sup>, Richard Thomas<sup>1</sup>, John Gulliver<sup>2</sup>, Joshua Vande Hey<sup>3</sup>, John Macleod<sup>1</sup>*

*1. ALSPAC, University of Bristol, Bristol, United Kingdom.*

*2. SAHSU, Imperial College London, London, United Kingdom.*

*3. Earth Observation Science Group, University of Leicester, Leicester, United Kingdom.*

**Abstract:** Introduction Novel platforms are needed to link spatially determined environmental data with longitudinal population study data. However, the relationship between spatial data and disclosure risk raises confidentiality concerns that need addressing. Methods Within the Avon Longitudinal Study of Parents And Children (ALSPAC) birth cohort, we aimed to establish generalisable mechanisms for spatial linkage using a 'Data Safe Haven' framework (Burton et al. 2015). Technical processes (e.g. geocoding participants' address records, developing an 'engine' for linking to exposure data) were tested for acceptability with participant advisors in focus-groups and tuned to meet regulatory requirements (e.g. ISO27001 security accreditation). We are applying this in an exemplar investigation assessing in utero NO<sub>2</sub> exposure with later childhood respiratory outcomes. Results Participants' viewed location based research as acceptable, but expressed clear expectations that location data processing should be restricted to trusted study staff. Concerns were raised regarding GPS location tracing data. This necessitates a 'split stage' protocol, where personal identifiers are handled separately from exposure data and epidemiological analysis. Daily NO<sub>2</sub> exposure from pregnancy onwards was estimated from modeled concentrations using an ensemble approach and validated using contemporaneous sensors. Participants' location data was geocoded and linked to NO<sub>2</sub> at spatial locations using the new open source ALGAE privacy-preserving geocoding engine; creating a lifetime residential and exposure history for study participants. Conclusions Participants expect that confidentiality risks introduced by spatial research are controlled. Software tools with aligned governance controls can facilitate linkage of spatial environmental data in large cohorts, to support large-scale epidemiological studies of environmental exposures.

### **S01.01.34. The Canadian Urban Environmental Health Research Consortium (CANUE)**

Dany Doiron

*Dany Doiron<sup>1</sup>, Eleanor Setton<sup>2</sup>, Evan Seed<sup>3</sup>, Mahdi Shooshtari<sup>2</sup>, Jeffrey Brook<sup>3</sup>*

*1. Research Institute of the McGill University Health Centre, Montreal, QC, Canada.*

*2. Geography, University of Victoria, Victoria, BC, Canada.*

*3. Dalla Lana School of Public Health, University of Toronto, Toronto, ON, Canada.*

Abstract: CANUE is a Canadian Institutes of Health Research-funded platform for supporting environmental health research. CANUE collates and generates standardized environmental data on air and noise pollution, land use, green/natural spaces, climate change/extreme weather, and socioeconomic conditions for every postal code in Canada and makes them freely available to researchers. A dozen national exposure databases and related metadata files are now available through CANUE, and new regional and national datasets are regularly added to a central database. Streamlined processes for data sharing and integration have been developed to facilitate easy merging with existing observational cohorts and administrative health databases from across Canada. Substantial consultation has also taken place with a wide range of health data holders to establish appropriate processes for receiving and managing environmental data, with particular focus on addressing challenges presented by differing ethics, consent and confidentiality requirements. The CANUE collaborative model illustrates how the scientific potential and cost-effectiveness of environmental health research can be improved through better coordination among researchers and data holders. Processes facilitating the merging of area-level environmental exposure datasets with some of Canada's largest cohort and health databases help accelerate the research process by making analysis-ready data available to investigators, create unprecedented opportunities to study how multiple environmental factors are linked to a wide range of health outcomes, and generally increase the use of health and population databases for environmental health research.

### **S01.01.35. Harmonisation of Air Pollution Exposures in the European ELAPSE Study**

Kees de Hoogh

*Kees de Hoogh<sup>1</sup>, Maciej Strak<sup>2</sup>, Jie Chen<sup>2</sup>, John Gulliver<sup>3</sup>, Ole Hertel<sup>4</sup>, Bert Brunekreef<sup>2</sup>, Gerard Hoek<sup>2</sup>*

- 1. Swiss Tropical and Public Health Institute, Basel, Switzerland.*
- 2. Institute for Risk Assessment Sciences, Utrecht University, Utrecht, Netherlands.*
- 3. MRC-PHE Centre for Environment and Health, Imperial College London, London, United Kingdom.*
- 4. Department of Environmental Science, Aarhus University, Aarhus, Denmark.*

Abstract: Epidemiological cohort studies have consistently found associations between long-term exposure to outdoor air pollution and adverse health effects. However, uncertainty about the shape of the concentration response function exists at low concentrations. Effects of Low-Level Air Pollution: A Study in Europe (ELAPSE) is a Europe-wide multi-centre collaboration addressing the issue of health effects at low air pollution. Fine scale hybrid LUR models, for PM<sub>2.5</sub>, NO<sub>2</sub>, Black Carbon and O<sub>3</sub> were developed incorporating land use and traffic data plus satellite observations and dispersion model estimates as additional predictor variables. Models were applied to 100x100m grids across Europe and transferred to each cohort, and linked to participants on the basis of address-level geocodes. Strict protocols were set up harmonising the linkup between exposure databases and the 11 individual and 7 administrative cohorts in 10 countries for a total of 35 million participants, dealing with cohort-specific requirements (e.g. georeferencing, governance procedures, data transfer, quality control etc.). A pooled analysis will be conducted of the 11 individual cohorts; data from the administrative cohorts are being analysed locally and combined by meta-analysis. Harmonised European-wide models for PM<sub>2.5</sub>, NO<sub>2</sub>, BC and O<sub>3</sub> were developed and explained respectively 71%, 58%, 51% and 62% of spatial variation in measured concentrations. Kriging proved an efficient technique to explain part of residual spatial variation for PM<sub>2.5</sub> and O<sub>3</sub>. To facilitate further harmonisation, the cohorts implemented the ELAPSE codebook, including specified definitions for socio-economic status. We successfully pooled data and assigned exposure for several of the individual cohorts, and assigned exposure to most of the administrative cohorts. Analyses of associations between low-level air pollution and morbidity and mortality endpoints are ongoing.

### **S01.01.36. U.S. Centers for Disease Control and Prevention's (CDC) National Environmental Public Health Tracking Program**

Fuyuen Yip

*Fuyuen Yip<sup>1</sup>*

*1. US Centers for Disease Control and Prevention, Atlanta, GA, United States.*

Abstract: The mission of the United States Centers for Disease Control and Prevention's (CDC) National Environmental Public Health Tracking Program (Tracking Program) is to provide information from a nationwide network of integrated health and environmental data that drives actions to improve the health of communities. In collaboration with partners, the Tracking Program identifies priority environmental health issues, determines key surveillance questions, and evaluates the utility of existing data for answering the question and informing the issue. Selected data are integrated into the National Environmental Public Health Tracking Network and used to (1) describe temporal and spatial trends in disease and potential environmental exposures, (2) identify populations most affected, (3) generate hypotheses about associations between health and environmental exposures, and (4) develop, guide, and assess the environmental public health policies and interventions aimed at reducing or eliminating health outcomes associated with environmental factors. Gaps in data are addressed by developing standards for new data collections, models, or new methodologies for using existing data, or by expanding the utility of non-traditional public health data. Current data challenges include the need for more temporally and spatially resolved data to better understand the complex relationships between environmental hazards, health outcomes, and risk factors at a local level. National standards are in development for systematically generating, analyzing, and disseminating small area data and real-time data that will allow for comparisons between different datasets over geography and time.

## S01.01J. Multi-Response and Multi-Pollutant Models for Environmental Exposure and Health: From Gap-Filling to Decorrelating Structure in Data

### **S01.01.37. Identification of Problematic Data Sections and Interpolation of Air Pollution Time-Series**

Dave Riegert

*Dave Riegert<sup>1</sup>, David J. Thomson<sup>1</sup>, Aaron Springford<sup>2</sup>*

*1. Mathematics and Statistics, Queen's University, Kingston, ON, Canada.*

*2. Weyerhaeuser, Seattle, WA, United States.*

**Abstract:** Obtaining reliable results from time-series analysis requires complete and error free data and many statistical tools require contiguous data to be usable at all. In the context of measurements from the National Air Pollution Surveillance (NAPS) network we discuss obtaining a data set for use in analysis. We focus on first identifying problematic sections of data and correcting these problems through interpolation, if applicable. A major concern during this process is that because this data is used in decision making it is especially important to avoid introducing new problems while attempting to repair other identified problems. In order to begin addressing any issues present we first must identify that a problem exists, quantify the problem, and flag the points in the data to be corrected. The simplest problem section to identify is one where the data are completely missing. More difficult to identify are sudden or gradual baseline shifts, runs of zero values, runs of saturated values, timing shifts in the data, quantization changes over time, and changes in the autocovariance structure of the data. If a section is to be interpolated we use an interpolation algorithm that is a hybrid Weiner interpolation and consists of an initial interpolation followed by filling each gap individually. This process is iterated until convergence. We discuss: 1) the framework used to allow reproducibility of correction routines and the ability to traceback which operations were performed in the case that any questions of validity arise; 2) the approaches used to identify problematic sections of data; and 3) the interpolation algorithm used.

### **S01.01.38. 15 Years of Air Quality (AQ) Objective Analysis Mapping over North America Using Real-Time Observations and Canadian Operational AQ Forecast Models**

Sylvain Ménard

*Sylvain Ménard<sup>1</sup>, Alain Robichaud<sup>1</sup>, Richard Ménard<sup>1</sup>, Didier Davignon<sup>1</sup>*

*1. Environment Canada, Dorval, QC, Canada.*

Abstract: The Regional Deterministic Air Quality Analysis (RDAQA) is a mapping of surface air pollutant concentration which combines numerical forecasts from the Regional Air Quality Deterministic Prediction System (RAQDPS) and hourly AQ observational data from monitoring surface networks over North America. These include Canadian measurement networks operated by the provinces, territories, and some municipalities and those networks covering the continental United States under the umbrella of EPA's national AIRNow program. The model forecasts and observations are combined based on an optimal interpolation algorithm. The current RDAQA has a horizontal spatial resolution of 10 km and is issued every hour. It provides our best knowledge of the current state of the atmosphere for surface pollutant concentration for chemical species like: ozone, NO<sub>2</sub>, NO, SO<sub>2</sub>, PM<sub>2.5</sub>, PM<sub>10</sub>. The RDAQA also provide a mapping of the Air Quality Health Index (AQHI) in quasi-real time and can be used by meteorologists in Environment Canada's regional forecast offices to inform the public on a daily basis about the health risk associated to short term exposure to air pollution. The RDAQA products available over an extended period of time can also be used by Health Canada and health consortium partners to study how Air Quality and other multiple environmental factors are linked to a wide range of health outcomes. A description of the RDAQA will be presented as well as data access and future plans.

### **S01.01.39. Geometric and Statistical Methods for Aggregating Predictors in Pollutant Risk Models**

Wesley Burr

*Wesley S. Burr<sup>1</sup>, Hwashin H. Shin<sup>2</sup>*

*1. Mathematics, Trent University, Peterborough, ON, Canada.*

*2. EHSRB, Health Canada, Ottawa, ON, Canada.*

Abstract: Multiple pollutant models are increasingly being researched for estimating population health risk due to air pollution while integrating the effects of more than one pollutant at a time. These models have varying approaches for dealing with the inherent correlated structure of air pollutants. In this talk, we examine two new methods for combining such correlated air pollutant predictors in risk models: A geometric and a statistical approach. In the geometric approach we consider the correlated structure of the pollutants embedded in a higher-dimensional space, and combine and interpret the risk estimates as existing on a surface in this space. In the statistical approach, we use the recently developed synthetic lag algorithm for estimation of the phase lag of individual components of the series, and de-correlate the air pollutants so as to make their risks approximately independent. The two methods are then compared and contrasted using several real-world air pollutant and health effect data sets.

## **S01.01.40. Correlated Responses in Air Pollution Regression Models**

Glen Takahara

*Glen Takahara<sup>1</sup>, Wesley S. Burr<sup>2</sup>*

*1. Mathematics and Statistics, Queen's University, Kingston, ON, Canada.*

*2. Mathematics, Trent University, Peterborough, ON, Canada.*

Abstract: Bivariate time series responses, specifically daily mortality and morbidity outcomes, in environmental air pollution regression models are of interest in population health studies for at least 2 reasons: (1) for combining risk measures spatially to form regional or national level risk estimates; the correlation between local risk estimates for the two responses can shape the local priors used in hierarchical Bayesian models, which are typically used for combining spatially differentiated estimates. (2) accounting for the two responses explicitly in the regression modeling can allow us to differentiate between pollutant effects on one response, e.g., mortality, that we may classify as "direct" and "indirect", the indirect effects being through the effect of the second response on the first. The current method for accounting the correlation between two responses is to fit each response separately, in two separate models using the same predictors, and then estimating the correlation between the two resulting risk estimates, as both are functions of the same predictors. This approach of estimating the correlation between risk estimates is tailored to address (1). However, it does not address (2). We propose estimating the correlation between the two time series responses in the spectral domain, where it is more commonly referred to as "coherence". In the frequency domain we determine the frequencies at which the two responses are coherent (i.e., correlated). Once this is done we use estimates of the coherent frequencies to estimate periodic structure that is common to both responses. In this way we can decompose one or both responses in the time domain, by inverting the decomposition in the frequency domain back to the time domain, into two or more series where each pair of series are either essentially uncorrelated or one series is a structural part of the other series. We will discuss how this can be used to address the issues raised in points (1) and (2) above.

## S01.01K. Novel Methods for Assessing Complex Exposure Mixtures in Environmental Epidemiology

### S01.01.41. Using Bayesian Shared Mean and Mixture Priors to Study Prenatal Endocrine Disrupting Chemical Mixtures and Neurodevelopment

Ghassan Hamra

*Ghassan Hamra<sup>1</sup>, Kristen Lyall<sup>2</sup>, Gayle Windham<sup>3</sup>, Antonia Calafat<sup>4</sup>, Andreas Sjodin<sup>4</sup>, Heather Volk<sup>5</sup>, Lisa Croen<sup>6</sup>*

- 1. Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States.*
- 2. Drexel University, Philadelphia, PA, United States.*
- 3. California Department of Public Health, Richmond, CA, United States.*
- 4. National Center for Environmental Health, Centers for Disease Control and Prevention, Atlanta, GA, United States.*
- 5. Mental Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States.*
- 6. Division of Research, Kaiser Permanente, Oakland, CA, United States.*

**Abstract:** Background: Exposure to endocrine disrupting compounds (EDCs) is unavoidable. Many EDCs are suspected to impact neurological development of children, especially when exposure is experienced during gestation. However, it is difficult to identify which EDCs are etiologically relevant, which is partly due to the fact that these exposures co-occur. EDC exposures must be studied within a single regression framework, but this task is often complicated by limitations in traditional statistical tools. Methods: We applied Bayesian statistical tools to study the association of a group of EDCs and ASD diagnosis in the Early Markers of Autism cohort, a population based case control study that took place in Southern California. There were 545 children who were diagnosed with Autism Spectrum Disorders based on DSM-IV-TR criteria, 181 with intellectual disability, and 418 general population controls. We applied a shared mean prior and a mixture prior to study the effects of a group of PCB and PBDE congeners, PFAS, and organochlorine pesticides. Chemicals were considered individually, or as a class of compounds (ie, summed PCBs). All models were adjusted for matching factors (child sex, month and year of birth), maternal age, race/ethnicity, parity, and maternal weight at the time samples were collected. Results: We estimated the change in ASD risk per 10-unit increase (ng/g) in EDC exposure. ASD risk was not elevated for any specific EDC. In both the case where we applied a shared mean or a mixture prior, the effect estimates were centered on or near the null. Equally, when we considered summed groups of PBDEs, PCBs, PFAS, and OC pesticides and applied a shared mean, the results were null for all chemical groups. Conclusion: Our results do not suggest a relationship for the EDCs considered here with ASD risk.

## **S01.01.42. A Bayesian Approach to Assess Prenatal Exposures to Metal Mixtures and Associations with Latent Patterns of Neurodevelopmental Trajectories**

Shelley Liu

*Shelley H. Liu<sup>1</sup>, David Bellinger<sup>2</sup>, Martha M. Téllez-Rojo<sup>3</sup>, Lourdes Schnaas<sup>4</sup>, Brent A. Coull<sup>5</sup>, Robert Wright<sup>6</sup>*

- 5. Harvard T.H. Chan School of Public Health, Boston, MA, United States.*
- 6. Icahn School of Medicine at Mount Sinai, New York, NY, United States.*

**Abstract:** Due to the rise of exposomic research, there is increasing interest in complex mixtures which reflect real life exposure scenarios. Currently, there is limited literature on how exposure to metal mixtures affect neurodevelopmental trajectories. Furthermore, the few existing studies typically do not account for heterogeneity of response to exposure among children, and instead assume that exposure to metal mixtures impacts each child's health to the same degree. In reality, there may be latent subgroups of children with distinct neurodevelopment trajectories, and the impacts of exposure to metal mixtures may differ across these subgroups. We investigate these questions by developing a two-stage statistical model combining growth mixture modeling and Bayesian kernel-learning methods. This novel statistical approach first identifies latent subgroups with growth mixture modeling using time-varying neurodevelopment scores. In a second step, we use a new statistical model called Bayesian varying coefficient kernel machine regression (BVCKMR), to separately analyze each latent subgroup to determine how metal mixture exposures at a single exposure window affect neurodevelopmental trajectories, while adjusting for covariates. BVCKMR can handle dozens of metal mixture components, allowing us to visualize interactions between up to four metal mixture components, while existing studies typically only focus on pairwise interactions. We illustrate this approach by applying it to the Programming Research in Obesity, Growth, Environment and Social Stressors (PROGRESS) prospective cohort study based in Mexico City. We will present the association between prenatal metal mixtures and child neurodevelopment, as assessed using the Bayley Scales of Infant and Toddler Development. We demonstrate that the relative importance and interaction patterns between metal mixture components differs by latent class, and show that latent classes may be differentially vulnerable to metal mixtures.

### **S01.01.43. Applying the Bayesian G-Formula to Estimate Impacts of Public Health Actions on Environmental Exposure Mixtures**

Alexander Keil

*Alexander Keil<sup>1</sup>, Amy Kalkbrenner<sup>3</sup>, Jessie Buckley<sup>2</sup>*

- 1. Epidemiology, UNC Chapel Hill, Chapel Hill, NC, United States.*
- 2. Department of Environmental Health & Engineering, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States.*
- 3. Environmental Health Sciences, Joseph J. Zilber School Of Public Health, University of Wisconsin Milwaukee, Milwaukee, WI, United States.*

Abstract: Environmental exposures do not occur in isolation. Studying environmental mixtures is of great importance, but presents many methodological difficulties. Epidemiological models are specified to estimate exposure-response surfaces, and must make necessary tradeoffs between interpretability and complexity to address aspects of mixtures such as co-exposure confounding and chemical interactions. Furthermore, the conventional approach does not often correspond to public health actions, where policies or regulations may impact a group of exposures within a given mixture. We demonstrate an alternative approach, using the Bayesian g-formula within a causal inference framework to estimate effects of public health actions on exposure mixtures, which allows for flexible models to control confounding and address interaction while also generating easily interpretable results. Additionally, this approach allows incorporation of prior information from toxicologic or epidemiologic studies. We demonstrate our approach in a study of birth outcomes in Milwaukee, Wisconsin in 2005-06 and 2011-12. We linked birth data (using maternal address) with census tract level air toxics data from an EPA emissions-based model, the National-scale Air Toxics Assessment. We estimated the expected prevalence of low birth weight and preterm birth that theoretically would have been observed following a hypothetical intervention to decommission 3 coal-fired power plants in Milwaukee County at the beginning of 2005, to reduce or eliminate several air toxics known to be emitted by coal-fired power plants. While our example is simplified, we demonstrate the utility of this approach for using observational data to directly evaluate policy choices and contrast possible public health actions. Additionally, our analytic approach offers a strategy to reduce the problems of large data demands and statistical assumptions currently required to resolve the epidemiological study of environmental mixtures.

#### **S01.01.44. Characterizing Exposure to Complex Environmental Mixtures with Self-Organizing Maps**

John Pearce

*John L. Pearce<sup>1</sup>*

*1. Public Health Sciences, Medical University of South Carolina, Charleston, SC, United States.*

Abstract: The complexity and dynamic nature of environmental pollution creates many challenges for health investigators seeking to illuminate health effects involving exposure to complex environmental mixtures. This presentation will introduce a statistical learning tool known as the self-organizing map (SOM) as a framework for developing exposure metrics that facilitate the estimation of joint health effects of multipollutant exposure. The first part of the talk will describe the SOM learning approach and will discuss tailoring the technique for epidemiological research. This will include detail on strategies for determining the number of mixtures for subsequent testing and general presentation of results. The second part of the talk will illustrate SOM through examples that center on using results for application within air pollution epidemiologic studies. This will include examples based on EPA's NCORE multipollutant monitoring data and application within an acute health effects study. At the end of the talk, viewers will better understand the benefits and limitations of using a self-organizing map framework for identifying, characterizing, and estimating joint health effects of complex exposures to multiple risk factors.

## 001.02A. Cancer and the Environment

### **001.02.01. Population Attributable Risk and Projected Population Impact Fractions for Lung Cancer and Outdoor Air Pollution in Canada**

Priyanka Gogna

- 3. Department of Health Sciences, Carleton University, Ottawa, ON, Canada.*
- 4. Dalla Lana School of Public Health, University of Toronto, Toronto, ON, Canada.*

**Abstract:** Introduction: Outdoor air pollution is classified as a carcinogen by IARC primarily on the basis of a relationship between PM<sub>2.5</sub> and NO<sub>2</sub> and lung cancer risk. This study evaluates the population attributable risk (PAR) and population impact fractions (PIFs) for counterfactual exposure distributions for PM<sub>2.5</sub> and NO<sub>2</sub> on lung cancer risk in Canada. In addition, census dissemination area-level PM<sub>2.5</sub> and NO<sub>2</sub> exposure measures from 1980-2014 were used to calculate PAR estimates, analysis of PM<sub>2.5</sub> and NO<sub>2</sub> trends overtime, and counterfactual PIFs. Methods: Using relative risk estimates calculated from a Canadian-specific meta-analysis, the relationship between PM<sub>2.5</sub> and NO<sub>2</sub> and lung cancer risk was modeled. This analysis assumed a log-linear dose response for a continuous exposure, representing levels during the relevant window of 20 years, with a 5-year lag. Exposure at the dissemination-area level, and a geographically weighted regression model was used to calculate PM<sub>2.5</sub> and NO<sub>2</sub> distributions from 1990-2009, allowing for PAR calculation for 2015, change in PM<sub>2.5</sub> and NO<sub>2</sub> levels overtime, and PIF counterfactuals. Results: Meta-analyses of four Canadian studies for PM<sub>2.5</sub> and NO<sub>2</sub> and lung cancer risk resulted in pooled relative risk estimates of 1.07 (95% CI: 1.03-1.10) per 10 µg/m<sup>3</sup> for PM<sub>2.5</sub>, and 1.05 (95% CI: 1.02-1.09) per 10 ppb for NO<sub>2</sub>. Calculated PAFs for PM<sub>2.5</sub> and NO<sub>2</sub> were 5.4% and 7.9% respectively. Analysis of trends overtime suggested levels have decreased by 0.27 per 10 µg/m<sup>3</sup> for PM<sub>2.5</sub> and 0.56 per 10 ppb for NO<sub>2</sub> per year from 1980-2014. In light of observed trends, a 50% reduction in PM<sub>2.5</sub> and NO<sub>2</sub> is considered feasible. Counterfactuals reducing exposure by 50% are associated with a PIF of 5.6% for PM<sub>2.5</sub>, and 4.0% for NO<sub>2</sub>. Conclusion: These results quantify the proportion of incident cancer cases in Canada that could be prevented through changes in modifiable environmental exposures. Planned analysis will calculate PIFs based on projected exposure scenarios.

## 001.02.02. Outdoor Particulate Matter (PM10) Exposure and Lung Cancer Risk in the EAGLE Study

**Abstract:** Background. Several cohort studies in Europe showed an association of outdoor PM10 exposure with lung cancer risk. Overall, cohort studies in North-America showed no association. Only a case-control study on lung cancer and PM10 in South Korea has so far been performed. Objectives. In this study we evaluated the association between exposure to particulate matter with aerodynamic diameter  $\leq 10 \mu\text{m}$  (PM10) and lung cancer risk within the Environment And Genetics in Lung cancer Etiology (EAGLE) study, a population-based case-control study performed in the Lombardy Region, north-west Italy, in 2002-2005, which enrolled 2100 cases and 2120 controls frequency-matched for area of residence, gender, and age. Methods. We included subjects living in the same city since 1980 with complete histories of smoking (active and passive). Fine resolution annual PM10 estimates obtained by applying land use regression modeling to satellite data calibrated with fixed site monitor measurements were used. We assigned each subject the PM10 annual average estimates for year 2000 based on enrollment address. We used logistic regression to calculate odds ratios (OR) and 95% confidence intervals (CI) adjusted for area, gender, age, education, smoking, diet, and exposure to occupational lung carcinogens. Results. We included 3473 subjects, 1665 cases (1318 men, 347 women) and 1808 controls (1368 men, 440 women), with annual average levels of PM10 ranging from 37.6 to 48.6  $\mu\text{g}/\text{m}^3$ . We found increasing lung cancer risk with increasing PM10 category (P-value for trend: 0.03). The OR per 10  $\mu\text{g}/\text{m}^3$  was 1.29 (95% CI: 0.95-1.72). The association appeared stronger for squamous cell carcinoma (OR 1.45). Conclusions. In a population living in highly polluted areas in Italy, our study added evidence to the existence of a positive association between PM10 exposure and risk of lung cancer. This study emphasizes the need to strengthen policies to reduce airborne pollution.

### **001.02.03. Ambient NO2 Exposure and Respiratory Cancer Risk in São Paulo, Brazil**

Abstract: The International Agency for Research on Cancer (IARC) has classified outdoor air pollution as carcinogenic to humans (Group 1). This evidence has been based on predominantly studies from the global North. However, there is a dearth of evidence from low-middle income countries, including those within South America. We studied the association between exposure to ambient air pollution and mortality of respiratory cancers in the city of São Paulo, Brazil. Mortality data (between 2002 and 2013) for all individuals above the age of 20 years was derived from the Municipal Department of Health. Outcomes of interest were coded by the International Classification of Diseases (ICD-10). A total of 19,500 deaths attributable to respiratory cancers (12,826 in men, 6,674 in women) were geocoded by residential zip code. Annual estimates of NO<sub>2</sub> (between 1997 and 2011) were obtained from the global NO<sub>2</sub> land use regression model. Study population was divided in five exposure groups based on centiles of exposure: 0-25, 26-50, 51-75, 76-90 and > 90. Age-adjusted Binomial Negative Regression models were developed, stratifying by deprivation index and gender. We observed an increased risk of respiratory mortality in association with increased NO<sub>2</sub> concentrations. The IRRs for all individuals ranged from 1.10 (95% CI 1.03-1.18), in the lower exposed group, to 1.30 (95% CI 1.20-1.41) in the highest exposed group. The IRRs among men ranged from 1.07 (95% CI 0.98-1.16) to 1.26 (95% CI 1.14-1.39) and women ranged from 1.16 (95% CI 1.04-1.30) to 1.36 (95% CI 1.20-1.55). Our results showed that exposure to ambient NO<sub>2</sub> were associated with an increased risk of mortality of respiratory cancers in the city of São Paulo. These results strengthen the observation on air pollution and lung cancer risk by extending the evidence base to South-America aiding to a more refined estimate of the Global Burden of Disease of air pollution to health.

## **001.02.04. Cancer Incidence in the Agricultural Health Study Farmers: Is the Lung Cancer Deficit Due to Endotoxin?**

Catherine Lerro

*Catherine C. Lerro<sup>1</sup>, Stella Koutros<sup>1</sup>, Gabriella Andreotti<sup>1</sup>, Lydia M. *3. Department of Epidemiology, University of Iowa, Iowa City, IA, United States.*

*4. Division of Cancer Epidemiology and Genetics, Biostatistics Branch, National Cancer Institute, Rockville, MD, United States.*

Abstract: Compared to the general population, agricultural populations have lower incidence of overall cancer, in part driven by lower lung cancer rates. This deficit is partially due to lifestyle factors (e.g. lower smoking rates). Endotoxin, a component of gram-negative bacterial cell walls, is a common exposure among farmers and is associated with lower lung cancer risk. In Agricultural Health Study (AHS) farmers, we evaluated overall cancer incidence, and the contribution of endotoxin to the observed lung cancer deficit. We calculated age, year, sex, and race-adjusted standardized incidence ratios (SIR) and 95% confidence intervals (CI) for individual cancer sites in the AHS relative to the general population in Iowa and North Carolina. For lung cancers, we stratified SIRs by AHS-reported smoking and likely endotoxin exposure (raise animals or handle stored grain  $\geq$ once/year). Overall AHS cancer incidence was lower than the general population (n=8256, SIR=0.91, CI:0.89-0.93), with deficits for lung, bladder, pancreas, and liver cancer, and excesses for lip and prostate cancer, B-cell lymphoma, and acute myeloid leukemia. Lung cancer incidence in the cohort was about half of that in the general population (SIR=0.51, CI:0.48-0.55). Comparing AHS smokers to the general population (smokers and non-smokers), we still observed fewer than expected lung cancers (SIR=0.84, CI:0.78-0.91). The deficit of lung cancers remained for endotoxin exposed smokers (SIR=0.74, CI:0.67-0.81), while among endotoxin unexposed smokers we observed a lung cancer excess (SIR=1.15, CI:1.01-1.30). AHS cancer incidence patterns may give us clues to farm exposures' relevance to cancer etiology. Lung cancer incidence was lower than expected in the general population; smoking did not entirely explain the deficit. Endotoxin exposure is protective against lung cancer, and along with lower rates of smoking may contribute to the low lung cancer incidence in our agricultural study population.

## **001.02.05. Prostate Cancer Characteristics Are Associated with Overall Environmental Quality**

Jyotsna Jagai

*Jyotsna Jagai<sup>1</sup>, Achal Patel<sup>2</sup>, Danelle Lobdell<sup>2</sup>, David Greenwald<sup>3</sup>, Michael Abern<sup>3</sup>*

**Abstract:** Prostate cancer (PC) is one of the most common cancer types in the United States (US). Cumulative environmental exposures have been associated with PC incidence. However, the impact of cumulative environmental exposures on PC aggressiveness is not well understood. To address this gap, we utilize the U.S. Environmental Protection Agency's (USEPA) Environmental Quality Index (EQI) to estimate county-level environmental quality in the US. The EQI captures exposures to  $\geq 200$  environmental factors across five domains (air, water, land, sociodemographic, and built) for 2000-2005. For persons diagnosed with PC from 2010-2014 ( $n=252,313$ ), prostate specific antigen (PSA), biopsy Gleason score (bGS), and individual level covariates (age, sex, race, etc) from the Surveillance, Epidemiology, and End Results Program (SEER) were linked to the EQI based on place of residence. PSA, a measure of protein produced by the prostate gland and used as a screening tool, was dichotomized ( $PSA \geq 20$  vs.  $< 20$ ) and bGS, a score used to assess the aggressiveness of PC, was also dichotomized (high grade vs. low grade). We used mixed effects logistic regression to model EQI and domain-specific indices as quartiles (Q4; worst environment) to estimate odds ratio (OR) and 95% confidence interval (CI) for PC characteristics adjusting for individual-level covariates. PSA at diagnosis was not associated with overall environmental quality (EQIQ4:  $OR=0.96(0.86,1.06)$ ). Overall environmental quality was positively associated with increased odds of more aggressive PC as measured by bGS (EQIQ4:  $OR=1.14(1.02,1.28)$ ) with the strongest associations seen in the sociodemographic (SDQ4:  $OR=1.26(1.14,1.39)$ ) and built (BQ4:  $OR=1.14(1.02,1.27)$ ) domains. These results suggest associations between poor environmental quality and more aggressive PC at diagnosis. However, additional research is required to understand specific environmental drivers of PC aggressiveness. This abstract does not necessarily reflect USEPA policy.

## **O01.02.06. Public Health Ontario's Environmental Burden of Disease Project**

*2. Cancer Care Ontario, Toronto, ON, Canada.*

**Abstract:** Previous estimates of the portion of disease attributable to exposure to environmental hazards range from 3% to 23%. Public Health Ontario (PHO), a Crown corporation that provides scientific and technical advice to decision-makers in order to protect and promote the health of Ontarians, is working to estimate the environmental burden of disease (EBD) for its ~14 million residents. Due to methodological and operational considerations, we separated the diseases into cancer and "non-cancer" categories and generated the estimates sequentially. First, PHO collaborated with Cancer Care Ontario to assess cancer risk from population-level exposure to 23 carcinogens found in indoor and outdoor air, food, drinking water, and indoor dust using predominantly a risk assessment framework. The work, published in 2016, identified exposure to sunlight, radon, and air pollution as the top contributors to the environmental burden of cancer in Ontario. Since then, PHO has focused on estimating non-cancer diseases attributable to 11 environmental exposures including air pollution, foodborne and waterborne pathogens, aeroallergens, temperature, noise, and radiation. Leveraging exposure, census, and health administrative data, we conducted a probabilistic EBD analysis to estimate the physician office visits, emergency department visits, hospitalizations, and deaths attributable to the first four exposures listed above. Based on our approach, for example, we attributed approximately 2,000 hospitalizations and 6,000 premature deaths to air pollution and 7,000 hospitalizations and 100 premature deaths to foodborne pathogens (mean values). We plan to rank the burden across all environmental exposures, including the 23 carcinogens. Knowledge translation products and activities will continue to be tailored to reach decision-makers with the ultimate aim of reducing population-level exposure to high priority environmental hazards in Ontario.

## 001.02B. Cardiopulmonary Outcomes Associated with Long-Term Exposure to Air Pollution

### 001.02.07. Long-Term Exposure to Air Pollution and the Incidence of Chronic Obstructive Pulmonary Disease (COPD) and Asthma: A Population-Based Cohort Study in Ontario, Canada

**Abstract:** Background. Air pollution affects respiratory health, particularly children's lung development and exacerbation of chronic obstructive pulmonary disease (COPD). As the role of low air pollution levels in the development of COPD and adult-onset asthma remains uncertain, we examined their associations and characterized the shapes of concentration-response (CR) relationships in Ontario, Canada. Methods. We conducted a population-based cohort study of ~5.1 million adults, who were aged  $\geq 35$  years and free of asthma or COPD at baseline. From 2001 to 2015, we estimated 3-year average exposures of fine particles (PM<sub>2.5</sub>), nitrogen dioxide (NO<sub>2</sub>), and ozone (O<sub>3</sub>) from satellite-derived data, land-use regression models, and fusion-based methods, respectively, at residential postal codes. Oxidant capacity (Ox) was the redox-weighted average of NO<sub>2</sub> and O<sub>3</sub> (Ox). We used Cox proportional hazards models to estimate associations between air pollutants and outcomes, while controlling for individual and contextual covariates. We also conducted sensitivity analyses, such as further adjusting for deprivation. The shape of the CR relationship was examined using newly developed non-linear risk models based on optimal transformation of exposure concentrations. Results. 340,733 and 218,005 individuals developed COPD and asthma, respectively. Each interquartile range increase of PM<sub>2.5</sub> was associated with a 7% increase in the incidence of COPD (95% CI: 1.06-1.08). Similarly, NO<sub>2</sub>, O<sub>3</sub>, and Ox were significantly associated with 3-4% increased risk of COPD. We did not detect any strong evidence linking air pollution to asthma. Similar results were observed in most sensitivity analyses. When adjusting for deprivation, the association between PM<sub>2.5</sub> and COPD attenuated slightly (HR 1.04; 1.03-1.05), whereas O<sub>3</sub> and Ox attenuated to the null. The CR relationships for COPD showed sublinear associations. Conclusions. Exposure to air pollution was associated with increased COPD incidence, but not with asthma.

## 001.02.08. Associations between Ambient Air Pollution Exposure, Lung Function and COPD: Results from the UK Biobank Cohort

Dany Doiron

*Dany Doiron<sup>1</sup>, Anna Hansell<sup>2</sup>, Nicole Probst-Hensch<sup>3</sup>, Kees de Hoogh<sup>3</sup>*

*1. Research Institute of the McGill University Health Centre, Montreal, QC, Canada.*

*2. Small Area Health Statistics Unit, MRC-PHE Centre for Environment and Health, Department of Epidemiology and Biostatistics, Imperial College London, London, United Kingdom.*

*3. Swiss Tropical and Public Health Institute, Basel, Switzerland.*

**Abstract:** Introduction Ambient air pollution increases the risk of respiratory mortality but evidence for impacts on lung function and obstructive lung disease is less well established. Methods Modeled ambient particulate matter (PM<sub>2.5</sub>, PM<sub>10</sub> and PM<sub>coarse</sub>) and nitrogen dioxide (NO<sub>2</sub>) concentrations were linked to residential addresses of 242 159 UK Biobank Cohort participants. Cross-sectional analyses were performed to examine the relationship between air pollutant concentrations and forced expiratory volume in 1 second (FEV<sub>1</sub>), forced vital capacity (FVC), and COPD (FEV<sub>1</sub>/FVC < lower limit of normal), controlling for relevant confounding factors. Stratified analyses were performed for sex, age, obesity, smoking status, household income, 'ever had asthma' status, and occupation associated with increased COPD risk. Results Mean annual PM<sub>2.5</sub> and NO<sub>2</sub> exposures were 9.92 µg/m<sup>3</sup> (SD: 1.04) and 26.23 µg/m<sup>3</sup> (SD: 7.54), respectively. NO<sub>2</sub> concentrations were highly correlated with PM<sub>2.5</sub> (r=0.87), but less so with other PM metrics. Higher exposure to all pollutants showed significant negative associations with lung function. A 5 µg/m<sup>3</sup> increase in PM<sub>2.5</sub> exposure was associated with lower FEV<sub>1</sub> (-77.86 mL [95%CI: -87.85, -67.87]) and FVC (-61.09 mL [95% CI -73.15, -49.03]). For each 10 µg/m<sup>3</sup> increase in NO<sub>2</sub>, lower FEV<sub>1</sub> (-32.26 mL [95%CI: -34.90, -29.62]) and FVC (-32.77 mL [95%CI: -35.96, -29.59]) were also observed. COPD prevalence was associated with higher concentrations of PM<sub>2.5</sub> (OR 1.42 [95%CI: 1.32 to 1.52], per 5 µg/m<sup>3</sup>) and NO<sub>2</sub> (1.10 [95%CI: 1.07, 1.12], per 10 µg/m<sup>3</sup>), but not with PM<sub>10</sub> or PM<sub>coarse</sub>. In lung function analyses, stronger association were seen for males, lower income households, and individuals with 'at-risk' occupations. COPD associations were stronger amongst obese, lower income and non-asthmatic participants. Conclusion Air pollutant concentrations were clearly associated with decreased lung function and increased COPD prevalence in this large cross-sectional analysis.

## **001.02.09. Ambient Air Pollution Exposure and Risk and Progression of Interstitial Lung Abnormalities: The Framingham Heart Study**

Mary Rice

*Mary B. Rice<sup>1</sup>, Wenyuan Li<sup>2</sup>, Elissa H. Wilker<sup>1</sup>, Joel D. Schwartz<sup>2</sup>, Qian Di<sup>2</sup>, Petros Koutrakis<sup>2</sup>, Diane Gold<sup>2</sup>, George R. Washko<sup>3</sup>, George T. O'Connor<sup>4</sup>, Gary M. Hunninghake<sup>3</sup>, Murray A. Mittleman<sup>2</sup>*

- 1. Department of Medicine, Beth Israel Deaconess Medical Center, Boston, MA, United States.*
- 2. Harvard T.H. Chan School of Public Health, Boston, MA, United States.*
- 3. Brigham and Women's Hospital, Boston, MA, United States.*
- 4. Boston University School of Medicine, Boston, MA, United States.*

**Abstract:** Background: Ambient air pollution accelerates lung function decline among adults, but few have examined if pollution affects risk and progression of interstitial lung disease. Aims: To evaluate associations of long-term exposure to fine particulate matter (PM<sub>2.5</sub>), elemental carbon (EC, an indicator of combustion-related pollution), and major roads with odds of interstitial lung abnormalities (ILA) and progression of ILA on repeated computed tomography (CT) imaging. Methods: We ascertained ILA on chest CT obtained from 2,618 Framingham participants from 2008-2011. Among 1,846 who completed a cardiac CT in 2002-2005, we determined interval ILA progression. We assigned distance from home address to major roadway, 2004-2008 PM<sub>2.5</sub> average estimated by a spatio-temporal model that uses satellite data, and 2004-2008 EC using a spatio-temporal prediction model. Logistic regression models were adjusted for age, sex, height, weight, cigarette smoking, second-hand tobacco, neighborhood household value, cohort, and date. Results: Among 2,618 chest CT's, 176 (6.7%) had ILA, 1,361 (52.0%) had no ILA, and 1,081 (41.3%) were indeterminate. Among 1,846 with preceding cardiac CT's, 118 (6.4%) had interval ILA progression, 956 (51.8%) had no ILA progression, and 772 (41.8%) were indeterminate. Median (interquartile range, IQR) 5-year exposure was 9.9 (1.3)  $\mu\text{g}/\text{m}^3$  for PM<sub>2.5</sub> and 0.44 (0.14)  $\mu\text{g}/\text{m}^3$  for EC. In fully adjusted models, an IQR difference in 5-year EC exposure was associated with a 1.26 (95% CI 1.03, 1.55) times greater odds of ILA, and a 1.33 (95% CI 1.02, 1.73) times greater odds of ILA progression. Associations were similar in multinomial regression models including indeterminate CT scans. We did not observe consistent associations of PM<sub>2.5</sub> or proximity to roadway with odds of ILA or ILA progression. Conclusions: Exposure to combustion-related pollution may increase risk of progressive ILA, however, associations with other measures of particulate pollution were inconclusive.

**Abstract:** Background: Atrial fibrillation (AF) is the most common heart rhythm disorder and is associated with substantial morbidity and mortality. Established risk factors explain only 50%-60% of AF cases, therefore identification of novel population-level risk factors is vital. Short-term exposures to air pollution have been associated with AF triggering, however, only a single study has examined associations between long-term exposures and AF incidence. Methods: We used information from the Women's Health Initiative to explore the association between annual average exposures to PM<sub>10</sub>, PM<sub>2.5</sub>, NO<sub>2</sub>, SO<sub>2</sub>, O<sub>3</sub>, and risk of incident AF. Exposures were estimated at each address from nationwide spatiotemporal models and distance to road was calculated. Cases of AF were identified through linkage with Centers for Medicare & Medicaid Services data. Time-varying Cox proportional-hazards regression models were adjusted for known AF risk factors and splines were used to assess deviations of the exposure-response functions from linearity. Results: Among 78,060 eligible participants, there were 15,288 incident cases of AF. Only associations with PM<sub>2.5</sub> were linear. Increasing exposures to PM<sub>2.5</sub>, PM<sub>10</sub>, and SO<sub>2</sub> were not associated with higher risk of AF. NO<sub>2</sub>, and living closer to a roadway, however, were associated with higher risks of AF. For example, women with annual average NO<sub>2</sub> exposures in the top quartile (17.1-48.4 ppb) had an HR=1.23 (95% CI: 1.17, 1.29) compared to those in the bottom quartile (0.4-8.0 ppb) and women living furthest from the

largest roads (>5,070m) had an HR=0.96 (95%CI:0.91, 0.99) compared to those living within 1,007m. Findings were similar in sensitivity analyses additionally adjusted for neighborhood SES. (N=70,962; NO2 top quartile HR=1.24 (95% CI: 1.17, 1.31); >5,070m HR=0.97 (95%CI: 0.92, 1.01)). Conclusions: Among this nationwide study of postmenopausal women, increases in traffic-related air pollution exposures were associated with an increased risk of AF.

## **O01.02.11. Associations between Outdoor Fine Particulate Matter Air Pollution and Cardiovascular Disease: Results from the Prospective Urban and Rural Epidemiology Study**

Andrew Larkin

*Perry Hystad<sup>1</sup>, Andrew Larkin<sup>1</sup>, Michael Brauer<sup>2</sup>*

- 1. College of Public Health and Human Sciences, Oregon State University, Corvallis, OR, United States.*
- 2. School of Population and Public Health, University of British Columbia, Vancouver, BC, Canada.*

**Abstract:** Background: Globally, outdoor fine particulate matter (PM<sub>2.5</sub>) air pollution is estimated to account for a substantial proportion of morbidity and mortality from Cardiovascular disease (CVD), yet few prospective studies have examined the full range of global PM<sub>2.5</sub> air pollution exposures. Methods: We evaluated the relationship between outdoor PM<sub>2.5</sub> and CVD for 152,115 adults aged 35-70 from 27 countries within the Prospective Urban and Rural Epidemiology (PURE) study. We estimated outdoor PM<sub>2.5</sub> concentrations (range: 2-103 µg/m<sup>3</sup>) for 721 urban/rural communities (representing neighborhood in urban areas and small villages in rural areas) using satellite estimates calibrated with available ground based monitoring data. Cox proportional hazard frailty models were used to examine relationships between community PM<sub>2.5</sub> and CVD events, controlling for a comprehensive set of individual, household and geographic covariates. Findings: After a median follow-up period of 8.7 years, we recorded 7,030 CVD events (CVD death or non-fatal myocardial infarction, stroke or heart failure) and 1,710 CVD deaths. We observed an adjusted hazard ratio of 1.08 (95% CI: 1.06-1.10) for CVD events per 10 µg/m<sup>3</sup> increase in PM<sub>2.5</sub>. A larger association was observed for stroke [HR: 1.14 (1.11-1.17)] compared to myocardial infarction [HR: 1.05 (1.02-1.09)] events. Results for CVD events were robust to all sensitivity analyses. There was no evidence of an association [HR: 0.98 (0.92-1.04)] for CVD mortality alone. Interpretation: Outdoor PM<sub>2.5</sub> was associated with increased CVD risk in this diverse global prospective cohort study.

## 001.02.12. Long-Term Exposure to Air Pollution and Incidence of Myocardial Infarction: A Danish Nurse Cohort Study

Zorana Andersen

Zorana J. Andersen<sup>1</sup>, Jeanette T. Jørgensen<sup>1</sup>, Matthias Matthias<sup>2</sup>, Jørgen Brandt<sup>2</sup>, Ole Hertel<sup>2</sup>, Claus Backalarz<sup>3</sup>, Jens Elgaard Laursen<sup>3</sup>, Mette Kildevæld Simonsen<sup>4</sup>, Elvira Vaclavik Brauner<sup>5</sup>

4. Diakonissestiftelsen and Parker Institute, Frederiksberg Hospital, Frederiksberg, Denmark.
5. Department of Growth and Reproduction, Juliane Marie Center, Capital Region, Copenhagen, Denmark.

**Abstract:** Background: Exposure to air pollution has been linked to coronary heart disease, yet still evidence on PM<sub>2.5</sub> and myocardial infarction (MI) incidence has been mixed. Here, we examined the association between long-term exposure to air pollution and incidence of MI. Methods: We used the data from a nationwide Danish Nurse Cohort on 22,438 female nurses (age > 44 years) who at recruitment in 1993 or 1999 reported information on CVD risk factors. We obtained data on incidence of MI from the Danish National Patient Register until end of 2014. Annual mean concentration of PM<sub>2.5</sub> and NO<sub>2</sub> at the nurse's residence since 1970 (1990 for PM<sub>2.5</sub>) was estimated using Danish USBM/AirGIS dispersion model, while road traffic noise levels since 1970 were estimated using Nord2000 model, as the annual mean of a weighted 24h average (Lden). We used time-varying cox regression models to examine the association between 1- and 3-year moving averages of PM<sub>2.5</sub> and 1-, 3-, 10-, and 23-year moving averages of NO<sub>2</sub> with MI incidence. Results: Of the 22,438 women, 590 developed MI during a mean follow-up of 18.3 years. We found statistically significant and positive association between 3-year mean of PM<sub>2.5</sub> and MI in crude model (hazard ratio; 95% confidence interval: 1.22; 1.08-1.37), which attenuated in a fully adjusted model (1.10; 0.95-1.27), per IQR of 5 µg/m<sup>3</sup>. Results were similar for 1-year mean PM<sub>2.5</sub> (1.09; 0.96-1.25) and unchanged after adjustment for road traffic noise (1.10; 0.95-1.27). We found statistically significant positive association between 23-year mean levels of NO<sub>2</sub> and MI in fully adjusted model without (1.10; 0.99-1.22) and with (1.14; 1.01-1.29) adjustment for road traffic noise, per IQR of 9 µg/m<sup>3</sup>. Associations were weaker with shorter exposure windows for NO<sub>2</sub> (1-, 3-, and 10-year moving averages). Conclusion: We found associations between long-term exposure to PM<sub>2.5</sub> and NO<sub>2</sub> and MI incidence, independent of road traffic noise.

## 001.02C. Characterizing Near-Road and Point Sources of Air Pollution

### **001.02.13. Estimating Exposures to Unconventional Oil and Gas Flaring Using Satellite Observations**

Meredith Franklin

- 2. University of Southern California, Los Angeles, CA, United States.*
- 3. San Francisco State University, San Francisco, CA, United States.*

**Abstract:** In recent years there has been a rapid rise in unconventional oil and gas (UOG) extraction, commonly known as fracking. Excess natural gas resulting from UOG extraction is disposed of through flaring, potentially leading to a major source of hazardous air pollution. Quantifying exposures from flaring is very difficult due to the irregularity in production, limited regulation of flaring activities, and sheer number of drilling sites. The Eagle Ford Shale in Southern Texas is one such region that has experienced a nearly tenfold increase in UOG activity since 2010, having a dramatic impact on the residents of this large but mostly rural community. Compounding the issue is the paucity of air quality monitoring, making it near impossible to estimate the impact of the UOG activities in the region. To overcome these issues, we harnessed satellite observations from the Visible Infrared Imaging Spectroradiometer (VIIRS) satellite, which through the recently developed Nightfire algorithm provides identification of locations of flaring sources along with estimates of radiant heat and source area. We applied hierarchical spatial clustering to estimate hotspots of satellite-identified flaring activity, and cross-referenced the clusters with drilling permit data. Seasonal estimates of VIIRS flaring frequency and mean radiant heat intensity were calculated to quantify the amount of flaring at the cluster locations. We identified approximately 47,000 nightly flares from April 2012 through December 2016 in the Eagle Ford Shale, and area of approximately 75,000 km<sup>2</sup>. Nearly 800,000 people live in this region, indicating the extent of flaring that is occurring in close proximity to populated areas. This work has shown that through careful processing of VIIRS Nightfire observations we can generate novel and objective exposure estimates of flaring from UOG activities in areas where traditional exposure assessment is not possible.

## **001.02.14. Strategic Communication of Exposure Science and Environmental Epidemiology**

Virginia Guidry

- 1. Office of Communications and Public Liaison, National Institute of Environmental Health Sciences, Research Triangle Park, NC, United States.*
- 2. National Center for Computational Toxicology, U.S. Environmental Protection Agency, Research Triangle Park, NC, United States.*
- 3. Office of Environmental Health Hazard Assessment, California Environmental Protection Agency, Sacramento, CA, United States.*

**Abstract:** Background: Complex environmental health problems require multidisciplinary solutions and public support. Exposure scientists and environmental epidemiologists can use a range of tools to expand the reach of their work and help translate research findings into informed decisions. We will describe how to manage an online presence, including social media profiles, with a professional lens. Objective: Engaging with traditional media and social media can be daunting, so we will share guidance and concrete examples of how to be effective practitioners. Discussion: Traditional media is still a key source of public information. Effective media interviews require understanding what journalists need, including a timely response and clear, plain language explanations. Describing your science in a non-technical way can be challenging and takes preparation. Social media must be used strategically to maintain high quality and value. We will share examples of message development, for research and related purposes, across social media platforms like Facebook and Twitter. LinkedIn, the premier networking tool, helps to form connections and expose your career to potential employers and collaborators. ResearchGate and Academia provide ways to share manuscripts, presentations, posters, and other communication formats. Such online tools can keep the work alive for much longer than the limited conference presentation time, with a broader audience. We will review environmental health-related examples from active practitioners, common pitfalls, and recommendations for best practices with these platforms. Conclusions: Strategic engagement between scientists and public stakeholders can increase the power and efficiency of science. Engaging in traditional and social media can facilitate the formation and growth of partnerships, increase public awareness of environmental health topics, and inform decisions that can help address environmental health issues on local and global scales.

## **001.02.15. The Mobile Observations of Ultrafine Particles (MOV-UP) Study: Winter 2018 Sampling**

Elena Austin

*Elena Austin<sup>1</sup>, Timothy Gould<sup>2</sup>, Jeff Shirai<sup>1</sup>, David Hardie<sup>1</sup>, Michael Yost<sup>1</sup>, Timothy V. Larson<sup>2</sup>, Edmund Seto<sup>1</sup>*

*1. Department of Environmental and Occupational Health Sciences, University of Washington, Seattle, WA, United States.*

*2. Department of Civil & Environmental Engineering, University of Washington, Seattle, WA, United States.*

Abstract: The Mobile Observations of Ultrafine Particles (MOV-UP) Study is a two-year project intended to quantify air quality impacts of air traffic for communities located near, and below the flight paths of the SeaTac airport. The study aims to assess ultrafine particle concentrations within 10 miles of the airport in the directions of aircraft take-offs and landings over the course of 4 seasons. To date, sampling has been completed for Winter 2018. Over this time period, 16 days of mobile sampling were conducted using a suite of mobile instruments capable of detecting particles between 10-20, 20-36 and >36 nm in diameter on a 10 second time-scale. Black carbon (BC) particle concentration was collected on the 10 second scale as well as the full range of particle size distribution from 10 nm to 1  $\mu$ m on the 1 minute time scale. The mean wind direction during the drives was from the SW. There were two days with wind from the NW, which resulted in reversal of the landing and take-off direction at the airport. A varimax rotated principal component analysis was performed on the 1 minute particle size distribution data and BC concentration, normalized to total particle count. Three components accounted for 74% of the variance observed. The first component, explaining 33% of the variance, shows high loadings of particles with median diameter of less than 20.5 nm. The second component, explaining 23% of the variance, shows high loadings of particles with median diameter of greater than 20.5 nm. The third component, explaining 18% of the variance, shows high proportion of black carbon. The geographic distribution of the component scores suggests that the first component is associated with the aircraft flight path. This study demonstrates the ability of mobile monitoring to detect variations in on-road particle size distribution that may be associated not only with vehicular traffic, but also with distance to flight path within 10 miles of an urban airport.

## **O01.02.16. Characterizing Urban Particulate Matter Vehicle Emission Spatial Distributions with On-Road Black Carbon and Particle Number Observations**

David Miller

Abstract: Distributed urban emissions contribute to spatially variable air pollutant exposures from neighborhood block to city-wide scales. It is challenging to attribute fine particulate matter (PM-2.5) exposure patterns associated with important public health impacts to specific sources. Tracking primary traffic PM emissions is essential due to diesel emission control policies with uncertain impacts as control technologies age across the vehicle fleet. We investigate spatiotemporal variations in on-road vehicle black carbon (BC), particle number (PN), nitrogen oxide (NO and NO<sub>2</sub>) emission factors to fingerprint the influence of heavy diesel vehicle emissions. Two Google Street-View vehicle platforms performed simultaneous daily mobile measurements in Houston, Texas across 38 census tract communities with a range of socioeconomic status and emission sources. These observations have unprecedented spatiotemporal coverage (~160 km per day from July 2017 to March 2018) and 1-5s time resolution, enabling characterization of exposures and vehicle emission factors aggregated across road segments (30-120m), hours and days of the week. We derive vehicle plume enhancements above background (~10s timescales) and fuel-based emission factors with enhancements relative to carbon dioxide (CO<sub>2</sub>). First, we quantify BC emission factors and their contributions to PM-2.5 enhancements to fingerprint diesel source plumes. Second, we assess the influence of diesel vehicles equipped with particulate filters that exhibit both higher NO oxidation to NO<sub>2</sub> and ultrafine mode particle numbers via NO<sub>2</sub> and PN emission factor distributions respectively. Our approach demonstrates the value of mobile monitoring to characterize vehicle PM source patterns and to evaluate their contributions relative to stationary sources (e.g. cement batch plants) in Houston. These insights are valuable to attribute spatial exposure patterns to specific sources and inform health impact studies and emission mitigation strategies.

## **O01.02.17. Variations in Roadside Gradients of Nitrogen Dioxide Observed in a Range of Urban and Rural Settings**

Ian Longley

Abstract: Although several previous studies have characterised roadside gradients in traffic-related air pollutants through intensive observational studies, and particularly nitrogen dioxide, it has been difficult to combine results to determine the role of the study setting (particularly climate and local built environment) on those gradients and therefore create a generalised model that can be used for exposure assessment beyond those study settings, or to investigate the role of urban planning in mitigating impacts. This paper combines analysis of 9 different observational studies conducted at different locations in the cities of Auckland and Wellington in New Zealand, and measurements for isolated roadside locations extracted from a national long-term monitoring dataset. Each observational study consisted of repeated roadside transects of passive samplers, whereas the national dataset consists of monthly samples for up to 10 years. Together, these data covered varied settings ranging from open rural sites to more built-up urban sites. Analysis showed that all observational data could be summarised using an exponential decay function. A steeper decay was found for sites that were more built-up or near roads with more congested traffic, but also at the rural study site. A shallower decay was found for more low-rise suburban locations and for roads with smoother traffic flow. Our simple generalised model tended to under-predict observed roadside concentrations in the Wellington region. Ongoing analysis is exploring whether this is related to this region's windy climate.

## **001.02.18. Errors Associated with the Use of Roadside Monitoring in the Estimation of Acute Traffic Pollutant-Related Health Effects**

Donghai Liang

*Donghai Liang<sup>1</sup>, Rachel Golan<sup>2</sup>, Jennifer Moutinho<sup>3</sup>, Howard Chang<sup>4</sup>, Roby Greenwald<sup>5</sup>, Stefanie Sarnat<sup>1</sup>, Armistead Russell<sup>3</sup>, Jeremy A. Sarnat<sup>1</sup>*

- 5. Environmental Health, Georgia State University, Atlanta, GA, United States.*

**Abstract:** Background. Near-road monitoring creates opportunities to provide direct measurement on traffic-related air pollutants (TRAPs) and to better understand the changing near-road environment. However, how such observations represent TRAP exposures for estimating adverse health effect in epidemiologic studies remains unknown. Methods. As part of the Dorm Room Inhalation to Vehicle Emission (DRIVE) study, we measured several common traffic indicators at six indoor and outdoor sites ranging from 0.01 to 2.3 km away from a heavily-trafficked highway artery in Atlanta. We examined spatiotemporal variability trends and assessed the potential for bias and errors when using a roadside monitor as a primary traffic pollution exposure surrogate, in lieu of more spatially-refined, proximal exposure indicators. Results. Primary pollutant species, including NO, CO, and BC declined to near background levels by 20 to 30 m from the highway source. Patterns of correlation among the sites also varied by pollutant and time of day. NO<sub>2</sub>, specifically, exhibited spatial trends that differed from other single-pollutant primary traffic indicators. Notably, roadside monitoring of NO, CO, and BC tended to be more strongly correlated with sites, both near and far from the road, during morning rush hour periods, and more weakly correlated during other periods of the day. We found pronounced attenuation of observed changes in health effects (ranging from 18.1 % near to 49.2% far from highway) when using roadside monitoring as a surrogate for true exposure, and the magnitude varied substantially over the course of the day. Conclusion. Epidemiologic studies using near-road monitoring stations as exposure metrics for individuals living in near-road settings, may be prone to substantial exposure measurement errors. Our findings indicate that near-road monitors should be used along with more spatially-resolved metric to accurately capture biologically-relevant exposure to primary traffic pollution.

- 6. Harvard University, Cambridge, MA, United States.*

**Abstract:** There is growing evidence that temperature increases associated with tropical deforestation are having negative impacts on human health and productivity. These changes are projected to disproportionately affect poor, rural populations. We report selected findings from a larger study that aims to characterize heat exposure in primary forest and cleared areas, describe how rural communities are adapting to deforestation, and investigate the impacts of increased heat exposure on human health and productivity. A total of 361 participants from ten villages in East Kalimantan, Indonesia were in the study. Continuous measurements in forested and cleared areas were collected in each village using 3MT heat stress monitors. Households completed surveys that included demographics, health status and medical conditions, and time-use modules. Mean maximum temperatures were 33°C and 37°C in forest and open areas, respectively, and mean forest temperatures were 2.6°C cooler than open areas. We find 74% of participants work only in open areas, while 26% work in forests and open areas. Self-reported heat-related illness symptoms in the past week were 4.1% higher among those working only in open areas. Participants reported modifying work schedules to adapt to heat, with nearly 75% of participants working less than in previous years and 37% unable to work the hours they would like in a day. Participants working only in open areas took longer midday breaks and worked longer afternoon shifts. Questions on future adaptation to hotter temperatures indicate more than a third of participants will work less or shift work schedules to avoid the hottest periods of the day. Our findings indicate that heat exposure is higher in deforested areas and adaptation strategies to avoid heat will impact work and productivity in this population.

## 001.02.20. Disappearing Seas: Assessing Dust and Respiratory Health in a Changing Climate

Jill Johnston

*Jill Johnston<sup>1</sup>, Shohreh F. Farzan<sup>1</sup>, Luis Olmedo<sup>2</sup>, Humberto Lugo<sup>2</sup>, Benjamin Steines<sup>3</sup>, Peter S. Thorne<sup>3</sup>*

*2. Comite Civico del Valle, Brawley, CA, United States.*

*3. University of Iowa, Iowa City, IA, United States.*

Abstract: Across the southwestern US, particulate matter (PM) in the form of wind-blown dust is emerging as an increasingly prevalent exposure of public health concern. Changing weather patterns, droughts and competing water demands are dramatically altering the landscape and creating conditions conducive to the production of wind-blown dust. In California, such factors are leading to the rapid shrinking of the Salton Sea, a 350-square mile land-locked "sea" situated near the southeastern rural border region known as the Imperial Valley. A regional water transfer agreement will accelerate the Sea's drying and it is anticipated that large swaths of the lakebed will become exposed, leaving behind highly emissive salt flats containing toxic metals, pesticides, and other contaminants. Through a community-academic partnership with Comite Civico del Valle and local elementary schools, we developed a children's respiratory health survey among 1st and 2nd graders to assess baseline health conditions in a rural environmental justice community and collected PM filters at schools to assess the composition of respirable dust. 292 families at four schools participated in the 2017 baseline survey (73% participation) of which 93% identified as Latino/a and 56% reported a household income below \$30,000 per year. 45% of children reported wheezing and 42% had allergy symptoms. Over one-quarter of the children (range 16-30% by school) reported having doctor diagnosed asthma and had used rescue medication in the past year. Preliminary analyses of filter samples during 3 sampling periods showed variability in PM levels by location and by sampling period. Highest average PM<sub>10</sub> and PM<sub>2.5</sub> levels were observed in May 2017. Filter samples also contained detectable levels of biological contaminants, including endotoxin and glucans, which also varied spatially and temporally, independent of PM levels. This work suggests a population vulnerable to the potential impacts of a disappearing Sea.

## **001.02.21. Climate Change and Health: A Historical Analysis of Vivax Malaria Outbreak in Moscow (Russia) during 1999-2008**

Natalia Shartova

*Natalia Shartova<sup>1</sup>, Varvara Mironova<sup>1</sup>, Mikhail Varentsov<sup>1</sup>, Mikhail Grischenko<sup>1</sup>, Viktor Krainov<sup>1</sup>, Pavel Konstantinov<sup>1</sup>*

*1. Geography, Lomonosov Moscow State University, Moscow, Russian Federation.*

**Abstract:** In the early 1990s vivax malaria resurged in Russia affecting the areas that had been malaria-free since 1960s. In total, at least 525 cases of local transmission were recorded during 1999-2009 in the European part of Russia alone. Moscow region consisting of two member states of Russian Federation, Moscow city and Moscow oblast', was most seriously affected with 386 autochthonous malaria cases, including 90 within the city of Moscow alone. The sources of infection were mostly labour migrants from Central Asian countries. The aim of this study is to analyze long-term climatic trends in respect to malaria transmission and to identify natural indicators characterizing the risk of vivax malaria reintroduction in a temperate climate using meteorology, remote sensing and geospatial analysis. Using meteorological data from 16 stations located in Moscow region for 1977-2016 we assessed the elements of malaria season by Moshkovsky's method. The distribution of malaria cases was analysed using Landsat and Spot 5 satellite imagery. The calculation of different environmental variables (including NDVI, LST, LULC etc.) derived from satellite images was conducted for almost 300 water bodies of Moscow city that had been identified as anopheline breeding places by malaria control programme. As a result, environmental indicators for territory typization in relation to malaria have been selected. An increasing trend of two indicators over the last 40 years has been observed: (1) the sums of effective temperatures (otherwise known as growing degree days, GDDs), and (2) the duration of the season of mosquito's effective infection. The most pronounced changes relate to the 2000s. Spatial heterogeneity of other indicators and their trends has been observed. An urban heat island of Moscow city affects malaria epidemiological parameters and became more intense during the period under study.

## 001.02.22. Climate Variability, School Calendar Pattern and Pertussis Epidemic

Yuzhou Zhang

*yuzhou zhang<sup>1</sup>, Hilary Bambrick<sup>1</sup>, Kerrie Mengersen<sup>1</sup>, Shilu Tong<sup>1</sup>, Lei Feng<sup>2</sup>, Li Zhang<sup>2</sup>, Guifang Liu<sup>2</sup>, Aiqiang Xu<sup>2</sup>, Wenbiao Hu<sup>1</sup>*

*1. QUT, Brisbane, QLD, Australia. 2. Shandong CDC, Jinan, China.*

**Abstract:** Pertussis remains endemic in many areas of the world as a vaccine preventable disease. Little research has been undertaken to discover the correlations between climate, socio-environmental factors and pertussis. This study aims to identify the potential risk factors of pertussis infection and develop an early warning model based on the identified predictors through a case study in China, which has seen a significant increase in cases since 2013. Weekly data on pertussis cases in Jinan from January, 2013 to December, 2017 were obtained from Chinese Infectious Disease Automated alert and Response System. Weather (ie., temperature and rainfall), school calendar pattern (SCP) and search metrics (SM) data in the same period were obtained from National Oceanic and Atmospheric Administration, Jinan Education Department and Baidu Index respectively. A time series decomposition procedure was used to discover the seasonal variations in pertussis. Time series seasonal autoregressive integrated moving average (SARIMA) and regression tree models were then used to combine climate data, SCP and SM to predict pertussis counts. A clear seasonal pattern of pertussis cases was observed with a peak in summer (July-September) and winter (November-January). The time series cross correlation analysis showed pertussis strongly correlated with SM at 2-week lag ( $r=0.75$ ;  $p<0.05$ ), temperature at 7-week lag ( $r=0.31$ ;  $p<0.05$ ) and rainfall at 0-week lag ( $r=0.28$ ;  $p<0.05$ ). The SARIMA model revealed the combination of weather and SM data improved the predictive performance ( $\beta_{temp}=0.14$ ,  $\beta_{rain}=0.08$ ,  $\beta_{SM}=0.06$ ,  $p < 0.05$ ). The regression tree model returned a relative risk (RR) of 2.1 for SCP periods, while the RR almost doubled to 3.9 for temperature $\geq 21$ o C and rainfall $\geq 0.4$ mm. This study offers insight into pertussis transmission dynamics and may facilitate decisions on future preventive strategies. Moreover, weather with SM may enhance pertussis surveillance as they can detect epidemics in real-time.

## **001.02.23. Impact of Climate Change Policies on Environmental Inequalities in Great Britain**

Heathen Walton

*Daniela Fecht<sup>1</sup>, Martin L. Williams<sup>2</sup>, Sean D. Beevers<sup>2</sup>, David Dajnak<sup>2</sup>, Nutthida Kitwiroon<sup>2</sup>, Heather Walton<sup>2</sup>, Melissa C. Lott<sup>3</sup>, Mireille B. Toledano<sup>1</sup>*

*2. Environmental Research Group, MRC-PHE Centre for Environment and Health, King's College London, London, United Kingdom.*

*3. University College London, London, United Kingdom.*

Abstract: The UK Climate Change Act of 2008 requires an 80% reduction in carbon dioxide-equivalent emissions by 2050 compared with 1990. Strategies implemented to achieve this target offer the opportunity to improve public health and reduce environmental inequalities across Great Britain. We investigated the effect of alternative pathways to achieve the carbon dioxide reduction target on particulate and gaseous air pollution levels across different subpopulations in Great Britain. We linked the sophisticated air quality model CMAQ-Urban with the energy systems model UK TIMES to predict air pollution concentrations in 2035 and 2050 for different scenarios (two scenarios meet the emissions reduction target, two do not). We aggregated model outputs (fine particulate matter [PM<sub>2.5</sub>], nitrogen dioxide [NO<sub>2</sub>] and ozone) to the small-area level (ward ~6000 people) and compared concentrations by ethnicity and socioeconomic status. We used data on ethnicity from the 2011 census to classify wards according to their ethnic composition as White or Non-White and a composite small-area socioeconomic indicator to rank wards from the most to least deprived 5th of wards. Both NO<sub>2</sub> and PM<sub>2.5</sub> concentrations were higher in Non-White compared to White wards (9.3 µg/m<sup>3</sup> NO<sub>2</sub> difference) in all scenarios, less so for ozone. In 2011, mean concentrations in the most deprived 5th of wards were 4.3 µg/m<sup>3</sup> higher compared to the least deprived (ratio = 1.37). This difference decreased by 2050 in all scenarios, for example, to 2.8 µg/m<sup>3</sup> in the baseline scenario, showing a narrowing in the air pollution inequality gap (ratio = 1.31). This general pattern varied by region. PM<sub>2.5</sub> and O<sub>3</sub> showed smaller differences. Despite significant reductions in NO<sub>2</sub> and modest reductions in PM<sub>2.5</sub> and ozone in 2050, air pollution inequalities still persist in all scenarios.

## **O01.02.24. Ethical Issues in Climate Change and Health: How Can Environmental Health Research Facilitate Transformative Changes?**

Mathilde Pascal

*Mathilde Pascal<sup>1</sup>*

*1. Santé publique France, Saint Maurice, France.*

**Abstract:** Our world is facing ecological and biological system changes of unprecedented speed, magnitude and extent. Climate change and biodiversity loss, together with other planetary changes, threaten human societies, and illustrate key frailties of our current approach through the applied sciences. First, its incapacity to trigger rapid actions based on scientific knowledge. It took three decades of scientific dissemination to obtain the political consensus of the Paris agreement. Yet, while numerous studies prove that human health is directly relevant to four key aspects of current climate negotiations (mitigation, adaptation, financing, and capacity development) it is seldom discussed as such. Second is the difficulty of thinking in terms of non-linear responses and tipping points. Indeed, the 2°C target of the Paris agreement does not guarantee that some tipping points will not be exceeded. Third is recognition of the impossibility, with current science, to capture the totality of the health impacts of planetary issues. "There is no planet B" emphasizes that there is no control population for research purposes. This problem is solved by considering the puzzle, piece by piece, but few studies explicitly recognize the limitations of this fragmented approach. Facing these frailties, and in the context of limited resources and time, we need to find new ways of thinking. Some researchers claim that critical research questions are no longer about the problems, but about how to facilitate the transformation of society to solve them, considering that we now are in a post-cautionary world. Perspectives include new forms of interdisciplinary collaborations, emphasis on practical knowledge, experiments, and the recognition of values. How can environmental health researchers introduce these perspectives into their work, and contribute to the shaping of new sustainable societies?

**Abstract:** Background: Exposure to pesticides has been associated with neurobehavioral deficits and structural brain anomalies in animals and humans. We examined the association between pesticide exposure and brain activity in 48 farm workers from the Zarcero County, Costa Rica. Methods: In May-August 2016, we collected urine samples from each worker and quantified concentrations of urinary metabolites for mancozeb (ethylenethiourea, ETU), chlorpyrifos (trichloropyridinol, TCPy), and pyrethroids (3-phenoxybenzoic acid, 3-PBA). We assessed brain activity throughout bilateral prefrontal cortices using functional near-infrared spectroscopy (fNIRS) while participants completed tasks related to verbal working memory (Sternberg test), executive function (Wisconsin Card Sort Test), and attention (go/no-go test). We estimated exposure-outcome associations using linear regression models adjusted for age and education. Results: Median (P25-P75) urinary ETU, TCPy, and 3-PBA creatinine-adjusted concentrations were 1.0 (0.5-1.8), 7.2 (3.3-13.6), and 1.4 (0.7-1.7) µg/L, respectively. We observed that higher urinary TCPy and 3-PBA creatinine-adjusted concentrations were associated with decreased working memory-related brain activity in all eight regions of interest. For example, brain activity at the most posterior region in the prefrontal cortex of the left hemisphere decreased 2.3 (-4.1, -0.5) and 3.3 (-5.5, -1.1) per two-fold increase in urinary TCPy and 3-PBA creatinine-adjusted concentrations, respectively. We also found that executive function-related brain activity at the most posterior region in the prefrontal cortex of the left hemisphere decreased 2.3 (-4.5, -0.1) and 3.6 (-6.7, -0.4) per two-fold increase in urinary ETU and 3-PBA creatinine-adjusted concentrations, respectively. Conclusion: Our findings indicate that farm workers with higher pesticide exposure levels may be under-recruiting neural resources compared to those with lower exposure levels.

## **001.02.26. Organophosphate Pesticide Exposure, Differential Genome-Wide DNA Methylation, and Biologic Function**

Kimberly Paul

Abstract: Organophosphates (OP) are widely used insecticides that acutely inhibit acetylcholinesterase enzyme activity. In our population-based of Parkinson's disease (PD), we have shown differential DNA methylation levels associated with OP exposure. Here we aim to describe the OP exposure related epigenetic profile using the PANTHER gene ontology classification system. We measured genome-wide DNA methylation levels (Illumina 450k) in 839 participants. We then first performed an epigenome-wide association study to assess the relationship between OP exposure (GIS-based) and methylation. After we assessed the associations between genome-wide methylation markers and OPs, we generated two sets of gene lists. First, genes from the significantly OP-associated CpGs (70 CpGs,  $p < 10e-07$ , 41 genes), and second, genes of CpGs less strictly associated ( $p < 5e-04$ ; 1077 CpGs, 662 genes). Using the PANTHER software, we compared these gene lists with the human gene database (21,042 genes) to test for overrepresentation of molecular functions, biologic processes, and PANTHER pathways using a Fisher's exact test with false discovery rate (FDR) correction. We found among both PD patients and controls, OP exposure was associated with acetylcholine pathways. From the top 41 genes, the most enriched pathway was nicotinic acetylcholine receptor signaling pathway, fold enrichment=15.63,  $p$ -value=1.01e-03, FDR=1.64e-01. From the 662 genes, the top pathway was muscarinic acetylcholine receptor 1 and 3 signaling, fold enrichment=3.90,  $p$ -value=5.36e-04, FDR=4.73e-02. A number of other molecular functions, biological processes, and cellular components were also enriched in the group of 662 genes. These include pyrophosphatase related catalytic activity ( $p$ -value=2.75e-05, FDR=2.64e-03) and postsynaptic membrane components ( $p$ -value=1.33e-03, FDR=2.13e-02). In this investigation, our results suggest that OP exposure influences DNA methylation levels in genes specifically related to acetylcholine pathways.

## **001.02.27. Epigenetic Effects of Gestational Smoking on Developmental Origin of Lung Function Trajectories from Age 10 to 26 Years**

Wilfried Karmaus

Abstract: Gestational smoking is known to effect DNA-methylation (DNAm) at epigenetic loci (CpGs) in offspring. The objective was to investigate whether these CpGs predict long-term health effects in offspring such as reduced lung function from childhood to adulthood (lung function trajectories). To this end, we tested associations of smoking-related CpGs with the trajectories. A population-based birth cohort was established in 1989 on the Isle of Wight, U.K. The study enrolled 1,456 children between 1989 and 1990. Longitudinal monitoring with lung function measurements (forced vital capacity - FVC, forced expiratory volume in 1 second - FEV1) was conducted at ages 10, 18, and 26 years. The FEV1/FVC ratio was calculated. DNAm was measured in Guthrie cards collected after birth and in peripheral blood at age 10 and 18 years. Due to large differences in lung function between males and females, statistical analyses were stratified by gender, adjusting for blood cell counts. Risk ratios for adverse trajectories were estimated using log-linear models, applying false discovery rates. Trajectories and DNAm at birth were available for 385 females and 395 males. For each outcome (FVC, FEV1, and FEV1/FVC) and in males and females, the trajectory analyses show two main profiles, of which one was with reduced function. In females, multiple CpGs of the PRDM8 gene (coding methyltransferases that predominantly act as negative regulators of transcription) were statistically significantly related to trajectories with reduced FVC, FEV1, and FEV1/FVC levels. In males, multiple CpGs on the NPR2 gene, coding membrane receptors for natriuretic peptides, were associated with reduced lung function trajectories. From birth to age 18, these CpGs seems to be characterized by a more stable methylation pattern. The results suggest that CpGs related to maternal smoking seems to establish a link between intra-uterine smoking exposure and reduced lung function trajectories from childhood to early adulthood.

## **001.02.28. The Association between Urinary Naphthol Level and Structural Change of the Brain - Brain Cortical Thinning and Ventricular Enlargement: A Cross-Sectional Study**

**Abstract:** Background: Dementia is one of the most common disease in South Korea. Active researches are underway for the early prediction of dementia, and image analysis is one of them. Among the structural changes in the brain caused by Alzheimer's disease, this study focused on cortical atrophy and changes related to ventricular enlargement, which are mainly observed at the early stage of onset. Finally We tried to explore that naphthol, one of the PHA(Polycyclic aromatic hydrocarbons), could be a factor in brain structural changes. Methods: A total of 769 subjects from a community-based cohort in South Korea were used in analysis. All subjects measured cortical thickness(mm), brain volume(m<sup>3</sup>), and ventricular volume(m<sup>3</sup>) for all areas of the brain by brain 3T MRI. To show a correlation between urinary naphthol level and structural change of the brain, the multiple linear regression method was used. The model was adjusted by age, sex, education level, body mass index, drinking, smoking, Physical activity, intracranial volume, family history of dementia, and other cardiovascular comorbidity. Subjects with neurological disorders, dementia and MCI(mild cognitive impairment) were excluded from the study. Results: In multiple linear regression models, higher naphthol level showed a decline right entorhinal cortex- One of the biomarkers of early dementia prediction-( $\beta=-0.0273$ , p-value : 0.0089), right superior parietal cortex( $\beta=-0.0079$ , p-value : 0.0328), and left inferior parietal cortex( $\beta=-0.0078$ , p-value : 0.0369). On the other hand, higher urinary naphthol level was associated with lateral ventricle( $\beta=22.9236$ , p-value : 0.0248) and third ventricular( $\beta=28.9807$ , p-value : 0.0325) size. Conclusions: The results of this analysis indicate that urinary naphthol level was partially related with brain cortex thinning and ventricular enlargement in subjects without neurological disease, or cognitive disorder.

**001.02.29. Mendelian Randomization of Arsenic Metabolism as a Risk Factor for Hypertensive- and Diabetes-Related Traits among Adults in the Hispanic Community Health Study/Study of Latinos (HCHS/SOL) Cohort**

Abstract: Much of the research that connects hypertension and diabetes to arsenic has been conducted in populations exposed through drinking water. Recently, dietary rice has been recognized as a significant source of arsenic. The objective of this analysis was to evaluate whether arsenic metabolism efficiency is associated with hypertension and diabetes using a Mendelian randomization framework in a population with high rice consumption but no known water arsenic exposure. Using 12,689 participants from the Hispanic Community Health Study/Study of Latinos, this study examined the relationship between estimated arsenic metabolism efficiency (defined as the percentages of inorganic arsenic, monomethylarsenate (MMA), and dimethylarsinate (DMA) species) and three hypertensive traits and seven diabetes-related traits. The analyses implemented a two-stage Mendelian randomization approach, with the genotype-arsenic metabolism relationships extracted from published literature, and the genotype-trait relationships estimated from a mixed-effect linear model within the HCHS/SOL population that controlled for the complex survey design and admixed ancestry. The analysis was stratified by rice consumption, dichotomized at the top 10th percentile. Among high consumers of rice, each estimated percentage point increase in MMA was associated with increases of 1.08 mmHg in systolic blood pressure and 0.82 mmHg in diastolic (p=0.047 and 0.0167, respectively). Inorganic arsenic was similarly associated with increased diastolic blood pressure (1.1 mmHg/percentage point; p=0.021). DMA, which represents more efficient arsenic metabolism, was associated with lowered diastolic blood pressure (-0.5 mmHg/percentage point; p=0.017). Among low rice consumers, no associations were observed. Evidence for a relationship with diabetes was equivocal. This suggests that dietary arsenic exposure through rice may be a contributor to high blood pressure in the Hispanic/Latino community.

### **O01.02.30. Neurocognitive Function in Adult Residents of a Mining District in Mexico after Reduction of Manganese Exposure**

Horacio Riojas Rodriguez

*Marlene Cortez-Lugo<sup>1</sup>, Horacio Riojas Rodriguez<sup>1</sup>, David Hernández-Bonilla<sup>1</sup>, Astrid Schilman<sup>1</sup>, Rodolfo Solís-Vivanco<sup>2</sup>, Sandra Rodríguez-Dozal<sup>1</sup>, Yaneth Rodríguez-Agudelo<sup>2</sup>, Sergio Montes<sup>2</sup>, Camilo Ríos<sup>2</sup>*

*2. National Institute of Neuology a, Ciudad de Mexico, Mexico.*

**Abstract:** Background.. Little is known on chronic air manganese exposure and its neurotoxic effects once the exposure has diminished. In 2002 adults residents living in communities located in a mining area were identified with adverse neurological effects associated with exposure to manganese in air. Given these results, an Environmental Program Management was designed and implemented.. Four years after the implementation same populations was evaluated with the same neuropsychological tests Objective. The aim of this study was to analyze changes in neurocognitive performance in adults exposed to air Mn and after an intervention and compared with a reference group. Methods. Motor function was evaluated using an adaptation of Luria-Nebraska test; for attention and working memory retention digit tests was used. Both tests was applied before and after the intervention in the same population (58 adults in the mining zone and 30 controls outside this zone) A Cumulative Exposure Index was built for pre and post intervention periods (2002 and 2013). The index was divided in three categories: 0= reference ( ; 1=Below the median and 2= equal or higher the median value. Logistic regression and lineal models for different tests considering age, scholarship, and lead levels were adjusted. Odds Ratios and mean scores on cognitive performance were compared according with exposure levels. Results. Eleven years after the first evaluation and four years after the intervention, significant reduction in air manganese was found. Regarding neuropsychological evaluation, exposed population showed similar performance compared with controls in some motor tests such as verbal regulation (significant improvement). However, this improvement was not observed in other areas such as dynamic organization of motor act, attention and memory work Conclusions. After reducing significantly air Mn concentrations in this areas, the adults show improvement in some of the neuropsychological test while other showed no changes

### **O01.02.31. Urine and Serum Biomarkers of Per- and Polyfluoroalkyl Substances (PFAS) and Fluorinated Alternatives for Human Exposure Assessment**

Antonia Calafat

*Antonia Calafat<sup>1</sup>, Kayoko Kato<sup>1</sup>, Xiaoyun Ye<sup>1</sup>*

*1. US Centers for Disease Control and Prevention, Atlanta, GA, United States.*

Abstract: Per- and polyfluoroalkyl substances (PFAS), man-made chemicals with highly fluorinated carbon chains, are used in many commercial applications. Trace levels of several long-chain PFAS, including perfluorooctane sulfonate (PFOS) and perfluorooctanoate (PFOA), have been detected in the blood of almost every American, while short-chain PFAS are seldom detected. These findings may reflect lower exposure to short-chain PFAS or that, in humans, short-chain PFAS eliminate efficiently in urine. Because of changes in manufacturing of long-chain PFAS, short-chain PFAS and fluorinated alternatives, including perfluoroalkyl ether carboxylic acids (e.g., GenX, ADONA), are increasingly used. Moreover, detection of PFAS and fluorinated alternatives in drinking water has raised concerns about potential implications to human health from exposure through contaminated water. We developed an analytical method adequate for large biomonitoring programs like the National Health and Nutrition Examination Survey (NHANES), and report concentrations of 15 C3-C11 PFAS, GenX, and ADONA in urine and serum collected in 2016 from a convenience sample of 50 American residents with no known exposure to these chemicals. In serum, we did not detect GenX or ADONA; detection frequency and concentration patterns of other PFAS agreed with those from NHANES. In urine, we did not detect fluorinated alternatives, and rather infrequently short-chain PFAS (e.g., perfluorobutanoate in 56% of samples, median=0.2 µg/L; 95th percentile=0.6 µg/L). Despite widespread presence in serum, long-chain PFAS in urine were non-detectable (<0.1 µg/L). These results suggest limited exposure to both short-chain PFAS and select fluorinated alternatives in this convenience population, and stress the relevance of selecting the correct biomonitoring matrix to characterize exposure. Disclaimer: The findings and conclusions in this report are those of the authors and do not necessarily represent the official position of the CDC.

## 001.02F. Exposures and Health Impacts of Perfluorinated Substances

### **001.02.32. Setting Bench Mark Dose Limits for Perfluorinated Substances with Epidemiological Data**

Tony Fletcher

*Tony Fletcher<sup>1</sup>, Thorhallur I. Halldórsson<sup>2</sup>*

*1. CEE, Public Health England, Chilton, United Kingdom.*

*2. University of Iceland, Reykjavik, Iceland.*

**Abstract:** Background/Aim: Limits set for exposure to PFOA (perfluoro-octanoic acid) and other perfluorinated alkyl substances (PFAS), whether as daily intake, water concentrations or serum concentrations, have mostly relied on extrapolation from animal experimental data, with attendant uncertainties. Using the largest available database with a wide range of serum PFOA concentrations, Bench Mark Doses (BMD) as a basis for limits are proposed using the epidemiological data directly. The European Food Standards Authority is also proposing BMDs for these chemicals drawing on epidemiological data. Methods: Using the most replicated health effect associated with serum PFOA - increased lipids, BMD methods have been applied to the largest suitable dataset, the C8 study. With no strong evidence of a threshold, at the lower end of the range (1 to 30 ng/ml) the relation between lipids and serum PFOA is close to linear, so a benchmark limit for hypocholesteremia (total cholesterol > 240 mg/dl) can be established for a given additional risk of this condition. A benchmark response rate (BMR) of a 1% change in response has been used for some epidemiological data and is used here. Results: Serum PFOA in 54,000 adults was median 28 ng/ml (1-99 pctile range 3 to 889). The BMD for PFOA at a 1% BMR, from models not including other PFAS, in terms of serum concentration of PFOA was 4.1 ng/ml, with corresponding BMDL at the lower confidence level of 2.8 ng/ml. PFOA and other PFAS are correlated and models with both exposures yielded shallower slopes and higher BMD values. Conclusions: A BMDL for PFOA of 2.8 ng/ml is close to population background average serum levels, although the BMDL is sensitive to several factors: selecting either change in average cholesterol or risk of high cholesterol, the arbitrary choice of BMR which should reflect the severity of the outcome (other have chosen 5%), and whether other PFAS are included. The inclusion of other PFAS leads to substantially higher BMDL values.

### **O01.02.33. Derivation of the Agency for Toxic Substances and Disease Registry's (ATSDR's) Provisional Minimal Risk Levels (MRLs) for PFOA, PFOS, PFHxS, and PFNA**

Melanie Buser

*Melanie C. Buser<sup>1</sup>*

*1. DTHHS/ETB, ATSDR, Atlanta, GA, United States.*

Abstract: An MRL is an estimate of daily exposure to a hazardous substance that is likely to be without appreciable risk of adverse health effects over a specified route and duration of exposure. Perfluoroalkyls are ubiquitous chemicals in the environment; they are readily absorbed but are not metabolized in humans or animals. The primary health effects of concern include hepatic, developmental, and immunotoxic effects. Limitations in the database precluded the use of human studies for MRL derivation, so laboratory animal studies were used. Because of interspecies differences in the toxicokinetics of perfluoroalkyls, there is uncertainty associated with extrapolation of external dose-response relationships from animals to humans. Therefore, rather than using dose as the point of departure (POD), we estimated PODs using animal serum perfluoroalkyl levels. An empirical pharmacokinetic model specific for animal species/strain/sex was used to estimate serum concentrations of perfluorooctanoic acid (PFOA) and perfluorooctane sulfonic acid (PFOS). Serum concentrations for perfluorohexane sulfonic acid (PFHxS) and perfluorononanoic acid (PFNA) were estimated using measured levels. Assuming that a serum concentration resulting in an effect in a laboratory animal would also result in an effect in humans, we calculated human equivalent doses (HEDs), which are defined as the continuous ingestion dose (mg/kg/day) that would result in steady-state serum concentrations of the perfluoroalkyl species equal to the serum concentration ( $\mu\text{g/mL}$ ) selected as the POD. MRLs were calculated by dividing the HEDs by uncertainty and/or modifying factors. The oral databases were considered adequate for derivation of provisional intermediate-duration MRLs for PFOA, PFOS, PFHxS, and PFNA. Hepatic, immune, and developmental endpoints were the most sensitive targets for PFOA and PFOS. The most sensitive targets were hepatic and thyroid endpoints for PFHxS, and body weight and developmental endpoints for PFNA.

## **001.02.34. Epidemiological Risk Assessment for PFOA**

Scott Bartell

*Scott M. Bartell<sup>1</sup>*

*1. Program in Public Health, University of California, Irvine, Irvine, CA, United States.*

**Abstract:** Introduction: Experimental studies of perfluorooctanoic acid (PFOA) and perfluorooctanesulfonic acid (PFOS) exposure in animals have reported developmental effects, liver and kidney toxicity, immune effects, and cancer. The US EPA performed dose-response modeling with some of those data to derive a health advisory of 70 parts per trillion (ppt) for the sum of PFOA and PFOS in drinking water. Relatively high quality human epidemiology studies are also available, particularly for PFOA, allowing risk estimation for communities with chronic exposure at 70 ppt in drinking water. Methods: Expected serum and cumulative serum PFOA concentrations due to long-term consumption of PFOA contaminated drinking water were calculated using a previously published one-compartment pharmacokinetic model. US incidence rates and selected epidemiological findings including several published C8 Science Panel studies were used to assess health risks for those exposures. For studies in which continuous dose-response analysis was not conducted, inverse variance weighted regression was used to interpolate health effect estimates across exposure categories. Results: Long-term consumption of 70 ppt PFOA in drinking water is expected to contribute about 8 ng/mL to serum PFOA above background contributions from other sources. Based on the previously published epidemiological findings, for lifetime exposure the expected number of excess cases of ulcerative colitis is about 5 per 10,000 exposed individuals, and the expected number of excess cases of thyroid cancer is about 2 per 100,000 exposed individuals. For prenatally exposed children, 8 ng/mL of PFOA in maternal serum has been associated with increased frequency of common colds and gastroenteritis, and decreased vaccine antibody concentrations. Conclusions: Biomarker-based epidemiological findings and pharmacokinetic models can be combined to inform health risk assessment for environmental contaminants.

## **O01.02.35. An Updated Meta-Analysis of the Association of Serum PFOA and Birthweight, with an Evaluation of Potential Biases**

Kyle Steenland

*Kyle Steenland<sup>1</sup>, Vaughn Barry<sup>1</sup>, David Savitz<sup>2</sup>*

*1. Environmental Health, Rollins School of Public Health, Emory U., Atlanta, GA, United States.*

*2. Epidemiology, Brown U., Providence, RI, United States.*

**Abstract:** Background: A recent meta-analysis of 15 studies of PFOA and birthweight found a change of -12.8 grams (95% CI -23.1, -2.38) per ng/ml in maternal or cord blood, and -27.1 grams (95% CI -50.6, -3.6) per log ng/ml PFOA. Almost all studies were done in low-exposed populations. There are now nine new studies, adding 6019 births to the 6937 births in the prior studies. Methods: We conducted a meta-analysis of 24 studies. We approximating untransformed results for study using log transformed PFOA, to allow combining all studies. We also included another large study, excluded from previous analyses, in a sensitivity analysis. Results: We found a change of birthweight of -10.5 grams (-16.7, -4.4) for every ng/ml of maternal or cord blood. After inclusion of one additional large study, we found virtually no evidence of a PFOA effect (-1.0 grams, 95% CI -2.4, 0.4). Restricting to studies in which blood was sampled from mothers early in the pregnancy or shortly before conception (5393 births), we found little association of PFOA with birthweight (-3.3 grams (-9.6, 3.0)). In studies when blood was sampled late in the pregnancy (7563 pregnancies), there was a lower birthweight with higher PFOA (-17.8 (-25.0, -10.6)). Conclusion: Current human evidence provides only modest support for decreased birthweight with increasing PFOA. Studies with a wide range of exposure, and studies with blood sampled early in pregnancy, showed little or no association of PFOA with birthweight. These are studies in which confounding and reverse causality would be of less importance.

### **001.02.36. Serum Per- and Polyfluoroalkyl Substances Levels and Their Predictors in a San Francisco Bay Area Chinese Community**

Kathleen Attfield

*Kathleen Attfield<sup>1</sup>, Farmmary Saephan<sup>2</sup>, Juan VillaRomero<sup>3</sup>, Nerissa Wu<sup>1</sup>*

*1. Environmental Health Investigations Branch, California Department of Public Health, Richmond, CA, United States.*

*2. APA Family Services, San Francisco, CA, United States.*

*3. California Department of Toxic Substances Control, Berkeley, CA, United States.*

**Abstract:** Background: Per- and poly-fluoroyl alkylsubstances (PFAS) have been widely detected in the environment, food, drinking water, and indoor dust, and are associated with adverse health effects. While some PFAS compounds are decreasing in human biomonitoring samples, some populations, such as Asian Americans, have been observed to have higher levels. Method: In 2016, Biomonitoring California and the APA Family Support Services collaborated on the Asian/Pacific Islander Community Exposures (ACE) Project to biomonitor Chinese adults in the San Francisco Bay Area. We recruited 100 participants and collected exposure information, urine, and blood samples. Sera were analyzed for 32 PFASs by liquid-liquid extraction high-performance liquid chromatography tandem mass spectrometry. Descriptive statistics were calculated and compared to 2013-2014 National Health and Nutrition Examination Survey (NHANES) levels. Additionally, we performed univariate and multivariable linear regression to identify demographic factors predicting increased exposure. Results: Fourteen PFAS were detected with 11 detected in over half of participants. ACE participants' geometric means were higher for perfluorooctane sulfonic acid (PFOS) (24%) and perfluorononanoic acid (PFNA) (43%) compared to all adults in the 2013-2014 NHANES but comparable to the subset of non-Hispanic Asians. For perfluorooctanoic acid (PFOA) and perfluorohexane sulfonic acid (PFHxS), our participants' levels were lower than both NHANES participants as a whole and the Asian subgroup. Demographic characteristics that were positively associated with several of the four most frequently detected chemicals included younger age, smaller portion of life spent in the US, and male sex. Percent of variance explained ranged from 10- 31%. Conclusion: This study illustrates the changing landscape of PFAS compound prevalence and the need for sub-population investigations to identify disparities in exposure for policy and education needs.

## 001.02G. Exposures in Contaminated Communities and Children's Health

### 001.02.37. In Utero Dioxin Exposure and Age at Menarche in the Seveso Second Generation

Marcella Warner

*Marcella Warner<sup>1</sup>, Stephen A. Rauch<sup>1</sup>, Jennifer Ames<sup>1</sup>, Paolo Mocarelli<sup>2</sup>, Paolo Brambilla<sup>2</sup>, Brenda Eskenazi<sup>1</sup>*

*1. School of Public Health, University of California Berkeley, Berkeley, CA, United States.*

*2. Department of Laboratory Medicine, Hospital of Desio, Desio-Milano, Italy.*

**Abstract:** Introduction: In utero exposure to 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD), a widespread environmental contaminant and potent endocrine disrupting compound, is associated with delayed pubertal development in animal studies. On July 10, 1976, an explosion at a chemical plant near Seveso, Italy exposed nearby residents to high levels of TCDD. The Seveso Women's Health Study (SWHS), initiated in 1996, is the only study to date of TCDD's health effects in a female population with the unique benefit of individual TCDD measured in blood collected near the time of the explosion. In 2014, we enrolled SWHS offspring (those exposed in utero to TCDD) in the Seveso Second Generation study. We examined the relationship of in utero TCDD exposure with reported age at onset of menarche among SWHS daughters. Methods: Age at onset of menarche (in years) was collected by maternal or self-report at interview in 341 SWHS daughters. We defined in utero TCDD exposure as initial (1976) maternal serum TCDD level and TCDD extrapolated to pregnancy. Data were analyzed using Cox proportional hazards models. Results: At interview, 287 daughters were postmenarche, averaging 25.6 ( $\pm 8.0$ ) years of age. The mean reported age at menarche was 12.1 ( $\pm 1.3$ ) years. Overall, we found no change in risk of menarche onset with a 10-fold increase in initial maternal TCDD (Hazard Ratio (HR) = 0.91, 95% CI 0.79, 1.06) or TCDD estimated at pregnancy (HR = 0.86, 95% CI 0.72, 1.03). When we considered maternal menarche status at explosion as a potentially sensitive developmental exposure window, TCDD estimated at pregnancy (log<sub>10</sub>) was associated with later age at menarche among daughters whose mothers were premenarche at explosion (HR = 0.71, 95% CI 0.50, 1.00) but not postmenarche at explosion (HR = 0.87, 95% CI 0.71, 1.07). Conclusions: These results suggest in utero exposure to TCDD may alter pubertal timing among daughters of women who were prepubescent at the time of the Seveso accident.

## **001.02.38. Peripubertal Urinary Arsenic Concentrations and Subsequent Insulin Resistance among Russian Boys**

**Abstract:** Introduction: Inorganic arsenic (iAs) has been associated with type 2 diabetes in adults, but there are few studies in children. We assessed the associations of peripubertal urinary iAs concentrations with insulin resistance (IR) at adolescence among boys in Chapaevsk, Russia. Methods: 516 8-9 year-old boys were enrolled from 2003-2005 in a prospective cohort study of environmental exposures, growth and puberty. At study entry, parents/guardians completed medical history and demographic questionnaires, and speciated urine As concentrations ( $\mu\text{g/L}$ ) were measured with ion chromatography coupled to ICP-MS; LOD=0.5, except arsenate (AsV) =1.0. Follow-up included annual physical exams and biennial collection of fasting blood samples. At ages 10-13 years, 430 boys had IR calculated by the homeostatic model.  $\Sigma\text{iAs}$  was calculated as the sum of arsenite (AsIII) + AsV, and levels were categorized as low (<1.0), medium (1.0-2.0), or high (>2.0). AsIII and AsV were also dichotomized as high vs. low ( $\geq$  vs. < LOD). Total As (tAs), calculated as  $\Sigma\text{iAs}$  + monomethylarsonic acid + dimethylarsenic acid, was categorized by quartiles. Associations of As species with IR were examined by multivariable generalized estimating equations for repeated measures, adjusted for urine specific gravity, age, and BMI. Results: 9.1% of boys had IR. The medians (max) of tAs, AsIII, AsV, and  $\Sigma\text{iAs}$  were 5.9 (254), 0.4 (57), 0.2 (15.7) and 0.7 (62)  $\mu\text{g/L}$ , respectively. In multivariable models, compared to low  $\Sigma\text{iAs}$ , the OR (95% CI) associated with medium and high  $\Sigma\text{iAs}$  were 1.90 (0.85, 4.28) and 2.42 (0.90, 6.52), p-trend=0.06. Of the iAs species, only AsV was associated with significantly increased odds of IR, with OR=2.75 (95% CI: 1.17, 6.47). tAs was not associated with IR. Conclusion: In this Russian cohort, higher peripubertal iAs was associated with increased odds of IR over four years of follow-up. Funded by EPA R82943701, NIEHS ES014370, ES000002 & ES024907.

## **001.02.39. Association between Maternal Psychosocial Stress during Pregnancy and Gestational Age in Puerto Rico**

Stephanie Eick

*Stephanie M. Eick<sup>5</sup>, Rafael E. Rios-McConnell<sup>2</sup>, Zaira Rosario<sup>2</sup>, Carmen Vélez-Vega<sup>2</sup>, John Meeker<sup>3</sup>, Akram Alshawabkeh<sup>4</sup>, Jose Cordero<sup>5</sup>, Kelly Ferguson<sup>1</sup>*

**Abstract:** Preterm birth (PTB), the leading cause of infant morbidity and mortality worldwide, disproportionately impacts infants in Puerto Rico (PR). Psychosocial stress may be an important risk factor for PTB and hasn't been examined in PR. We examined associations between stress and gestational age continuously and PTB (<37 weeks gestation) using multiple dimensions of stress in order to optimally define exposure. Stress was measured using the Perceived Stress Scale (PSS), Life Experiences Survey (LES), Center for Epidemiologic Studies-Depression (CES-D), and ENRICH Social Support Instrument (ESSI). We included 922 mother-infant pairs of the Puerto Rico Testsite for Exploring Contamination Threats (PROTECT) Cohort, which examines environmental risk factors for PTB in the Northern Karst region of PR. Data on stress measures was collected during the 3rd trimester visit, except for LES, which was collected at the 2nd trimester. Responses on each scale were scored to create a continuous measure. Higher scores on each scale, except the ESSI, were indicative of increased stress. There were 93 PTBs in this analysis. Lower maternal education, unemployment, and public insurance were more common among women who delivered preterm and were associated with higher scores on all stress measures. Higher scores on the PSS ( $\beta$ : 0.00; 95% CI (confidence interval): -0.02, 0.01), LES ( $\beta$ : 0.01; 95% CI: -0.02, 0.04), ESSI ( $\beta$ : 0.01; 95% CI: -0.02, 0.04), and CES-D scales ( $\beta$ : -0.01; 95% CI: -0.02, 0.01) were not associated with gestational age or PTB. Although our findings show that stress as measured by these scales is not associated PTB, there are other facets of stress, such as anxiety and neighborhood perceptions, that were not captured in our scales but may be important. Our study indicates that stress in pregnancy is not a major risk factor for PTB in our population. Other environmental exposures, such as chemical exposures in pregnancy, will be investigated in this population in the future.

## **001.02.40. Relationship between Thyroid Hormone Levels, Radiation Dose and IQ in Children Exposed In Utero by the Chernobyl Accident and Controls**

Liudmila Liutsko

*3. Division of Cancer Epidemiology and Genetics, National Cancer Institute, NIH, DHHS, Bethesda, MD, United States.*

**Abstract:** Background/Aim: A previous study, in Belarus, examined psychological development in 250 children exposed in utero to radiation from the Chernobyl accident in 1986 and 250 control children of the same age and sex from areas with little or no contamination. Significant differences in IQ (Intellectual quotient) were reported at age 7 years, but not later. We used data from this study to further explore the possible relationship between dose, thyroid hormones levels and IQ (at the adolescent period). Methods: The data set included information on thyroid hormones: - T3 (triiodothyronine) and T4 (thyroxine) levels; general IQ; radiation dose to the thyroid and gestation week at the time of the accident. We used MANOVA to screen the main significant factors of the study. Descriptive and non-parametric correlation analyses comparing those exposed in utero and the age/sex-matched control group were also conducted. Results: Using MANOVA, a significant increase in T4 and a significant decrease in T3 were seen when comparing those exposed in utero to controls ( $P < 0.05$ ); a significant interaction between dose group, sex and gestational quarter was also found on T4 levels ( $P = 0.001$ ). IQ was significantly decreased in the highest dose category compared to the two lowest dose groups, and was correlated with T3 in both the control and in utero exposed groups, though the direction of the correlation differed and it was significant only in the control group. Conclusion: This preliminary analysis suggests an association between dose and thyroid hormone levels and between these and IQ in our study population. Further in-depth analyses are underway to better characterise these, taking into account possible confounding factors.

## **001.02.41. Association between Liver Function, Hepatic Fibrosis Index and Urinary Thiodiglycolic Acid in School-Aged Children Living near a Petrochemical Complex**

Po-Chin Huang

*Po-Chin Huang<sup>1</sup>, Chih Wen Wang<sup>2</sup>, Kai-Wei Liao<sup>1</sup>, Chang-Chuan Chan<sup>3</sup>, Hung-Che Chiang<sup>4</sup>*

*3. Institute of Occupational Medicine and Industrial Hygiene, College of Public Health, National Taiwan University, Taipei, Taiwan.*

*4. College of Medicine, China Medical University, Taichung, Taiwan.*

**Abstract:** Background/Aim Whether children are susceptible to hepatotoxicity when exposed to vinyl chloride monomer (VCM) is unknown. Epidemiological studies revealed high prevalence of liver fibrosis and abnormal liver function in high VCM/PVC exposed workers, and previous study indicated that using urinary thiodiglycolic acid (TDGA) as a biomarker of VCM metabolites is reliable in children living near VCM/PVC factories. We aim to assess the association among urinary TDGA levels, liver function, and hepatic fibrosis in school-aged children. Methods 303 school-aged children (aged  $\geq 6$ - $<13$  years) were recruited in central Taiwan. First morning urine and blood samples were collected in each participants, and urinary TDGA levels were analyzed by LC/MS-MS. Liver function was determined by subclinical abnormal serum aspartate aminotransferase (AST) and alanine aminotransferase (ALT). Hepatic fibrosis was assessed by AST to platelet ratio index (APRI), and fibrosis-4 score (FIB-4). Results Median levels of all subjects urinary TDGA (range), AST/ALT (range; subclinically abnormal rate) were 95.2  $\mu\text{g/g-creatinine}$ , 26.0 IU/L (17.0-99.0; 26%)/15.0 IU/L (7.0-211.0; 6%), respectively. Third quartile of urinary TDGA levels in children (Q3:  $\geq 95.2$  -  $<160.0$   $\mu\text{g/g-creatinine}$ ) and highest quartile (Q4:  $\geq 160.0$   $\mu\text{g/g-creatinine}$ ) had significantly increased the odds ratio (OR) (Q3: OR= 3.54, 95% confidence interval (CI): 1.35-9.30; Q4: OR= 5.26, 95% CI: 1.93-14.31) of subclinically abnormal AST compared with those in the lowest quartile after adjustment for elementary schools, age, sex, BMI, annual family income, physical activity, and passive smoking. A trend for a dose-response ( $p$  for trend= 0.001) was also observed. Conclusions Our findings supported the hypothesis that urinary TDGA levels in children living near VCM/PVC industries are associated with susceptibility to hepatotoxicity.

## 001.02.42. Prenatal Pyrethroid Exposure and Behavioral Problems in 5-Year Old Children from the Infants' Environmental Health Study (ISA)

Jorge Ernesto Peñaloza Castañeda

*Jorge Ernesto Peñaloza Castañeda<sup>1</sup>, Ana Maria Mora<sup>1</sup>, Leonel Córdoba<sup>1</sup>, Jose Mora<sup>1</sup>, Brenda Eskenazi<sup>3</sup>, Christian Lindh<sup>2</sup>, Berna Van Wendel de Joode<sup>1</sup>*

1. *Universidad Nacional, Heredia, Costa Rica.*

2. *Division of Occupational Health and Medicine, Lund University, Lund, Sweden.*

3. *University of California at Berkeley, Berkeley, CA, United States.*

Abstract: Background: Pyrethroid insecticides may affect children's behavior, but data from prospective studies are rare. We examined whether prenatal pyrethroid exposure was associated with behavioral problems in 5-year old children from the Infants' Environmental Health Study (ISA). Methods: We interviewed mothers from 5-year old children (mean  $5.7 \pm 0.4$  years) ( $n=292$ ) about their child's behavior during the last two months, administering the Child Behavior Checklist (CBCL). We measured pesticide metabolite concentrations in maternal urine collected 1-3 times during pregnancy: DCCA for the pyrethroids permethrin, cypermethrin, and cyfluthrin, and 3PBA for permethrin, cypermethrin, and deltamethrin. We revised internal consistency of CBCL and analyzed sub-scales with Cronbach-alfa  $>0.7$ : Internalizing, Externalizing, Aggressive, Withdrawn behavior. We ran linear regression models for log-10 transformed prenatal metabolite concentrations and CBCL scales, adjusting for child age, child sex, stressful life events, HOME score, parity, maternal education, and maternal depression. We also examined effect-modification by sex. Results: Median (p25-p25) specific gravity-adjusted DCCA and 3PBA concentrations were 1.3 (0.8-2.4) and 0.8 (0.5-1.4)  $\mu\text{g/L}$  respectively. Higher DCCA concentrations were associated with increased internalizing problems ( $\beta=2.7$ , 95%CI -0.2-5.6, per ten-fold increase in exposure), particularly for boys ( $\beta=5.6$ , 95%CI 1.5-9.6, per ten-fold increase in exposure). Higher 3PBA concentrations were associated with increased externalizing problems ( $\beta=3.0$ , 95%CI -0.2-6.3, per ten-fold increase in exposure), particularly for boys ( $\beta=5.2$ , 95%CI 1.1 - 9.9 per ten-fold increase in exposure). For boys, higher 3PBA was also associated with internalizing problems and aggressive behavior:  $\beta=4.4$  (95%CI 1.1-8.6) and  $\beta=4.1$  (95%CI -0.1-8.3), respectively. Conclusion: Results suggest pyrethroids negatively affect young children's behavior, effects may be stronger for boys.

## O01.02H. Neurodevelopmental Outcomes Associated with Perinatal Exposure to Air Pollution

### **O01.02.43. Associations between Ambient Ozone and Fine Particulate Matter Exposures and Autism Spectrum Disorder in Metropolitan Cincinnati, Ohio**

John Kaufman

- 3. Cincinnati Children's Hospital Medical Center, Cincinnati, OH, United States.*

**Abstract:** Epidemiological studies have found fairly consistent associations between various air pollution measures and autism spectrum disorder (ASD) for prenatal and postnatal exposures. We examined associations between ASD and ambient fine particulate matter (PM<sub>2.5</sub>) and ozone concentrations during pregnancy through the 2nd year of life in a study of 428 ASD cases diagnosed at a large regional children's hospital in metropolitan Cincinnati, Ohio, frequency matched (15:1) on birth year to 6420 controls from Ohio birth records. We assigned daily PM<sub>2.5</sub> and ozone estimates from US EPA's Fused Air Quality Surfaces Using Downscaling model to each subject for each day of the study period (2005-2012) based on the census tract of the mother's residence at birth. We calculated adjusted odds ratios (aORs) with logistic regression models using continuous and categorical exposure period averages while adjusting for a priori confounders, other air pollutants, and multiple time windows of exposure. In the multipollutant models comparing highest to lowest sextiles, we detected elevated aORs for PM<sub>2.5</sub> in the 2nd trimester (aOR=1.41, 95% CI: 0.89, 2.24), 1st year of life (aOR=1.54, 95% CI: 0.98, 2.40), and cumulative period from pregnancy through the 2nd year of life (aOR=1.52, 95% CI: 1.00, 2.31), and for ozone in the 2nd year of life (aOR=1.29, 95% CI: 0.81, 2.05). When restricting to male sex, a strong risk factor for ASD, results increased for 3rd trimester PM<sub>2.5</sub> (aOR=1.36, 95% CI: 0.82, 2.25) and the cumulative period from pregnancy through the 2nd year (aOR=1.72, 95% CI: 1.08, 2.76). Though we saw limited evidence of exposure-response relationships, the elevated aORs for PM<sub>2.5</sub> in the upper exposure groups were similar in magnitude to those reported in previous studies. We did not see a consistent pattern of sensitive exposure periods between the two pollutants, but our strongest results for postnatal exposures agree with some previous research.

## **001.02.44. Prenatal and Infant Traffic Related Air Pollution and Autism Spectrum Disorder: A California State-Wide Study**

Ondine von Ehrenstein

*Ondine von Ehrenstein<sup>1</sup>, Xin Cui<sup>1</sup>, Hilary Aralis<sup>1</sup>, Jun Wu<sup>2</sup>, Myles Cockburn<sup>3</sup>, Beate Ritz<sup>1</sup>*

*1. UCLA, Los Angeles, CA, United States.*

*2. UCI, Irvine, CA, United States.*

*3. USC, Los Angeles, CA, United States.*

**Abstract:** Background: Studies are accumulating that suggest associations between air pollutants and autism spectrum disorder (ASD) in children. However, most studies include rather small numbers of cases. Our objective was to use data for the state of California focussing on road traffic related exposure during pregnancy and the first year of life to assess related risks for childhood ASD. Methods: We used a registry linkage design based on state-wide California birth data retrieved from Office of Vital Statistics birth rolls 1998-2010. ASD (at the time of our study assessed as autistic disorder (DSM IV-R)) cases (n~35,000) were identified through records maintained at the California Department of Developmental Services and linked to birth records. Birth record controls were matched on sex and year 1:10. Prenatal / first year road traffic related CO, NOx and PM2.5 concentrations from both gasoline and diesel vehicles were estimated using CALifornia LINE Source Dispersion Model 4, a modified Gaussian line-source dispersion model. We estimated risks using logistic regression. Results: Exposure during pregnancy to interquartile-range increases of the correlated pollutants CO, NOx and PM2.5 related to increased odds ratios (OR) for ASD, adjusting for maternal age, education, race/ethnicity, maternal birth place and other potential confounders: CO OR=1.14; 95% CI 1.13, 1.15; NOx OR=1.12; 1.10, 1.13; PM2.5 OR=1.13; 1.11, 1.14. Results were similar for boys and girls. Conclusions: Our state-wide population based study including a large number of ASD cases and avoiding participation bias, indicates increased risks for ASD of around 10% related to prenatal exposure to traffic generated air pollution. These findings confirm and extend earlier smaller studies suggesting the need for public health policies to regulate air pollution exposure to protect the developing fetus.

## **001.02.45. Prenatal PM2.5 Exposure and Neurodevelopment at 2 Years of Age in a Birth Cohort from Mexico City**

Magali Hurtado-Díaz

*Magali Hurtado-Díaz<sup>1</sup>, Horacio Riojas-Rodriguez<sup>1</sup>, Lourdes Schnaas<sup>3</sup>, Stephen J. Rothenberg<sup>1</sup>, Allan Just<sup>4</sup>, Itai Kloog<sup>5</sup>, Robert Wright<sup>4</sup>, David Hernández-Bonilla<sup>1</sup>, Martha M. Téllez-Rojo<sup>2</sup>*

**Abstract:** Background: The association between fine particles (PM2.5) and child development has not been assessed based on the Bayley Scales of Infant Development III (BSID-III), in which cognitive and language functioning are analyzed separately. Objective: To examine longitudinally the association between prenatal PM2.5 exposure and cognitive, language and motor development during the first two years of children's life. Methods: Analysis was conducted in PROGRESS, a longitudinal birth cohort enrolled during 2007-2011 in Mexico City. We used mixed-effect regression models to evaluate cognitive, language and motor scores of the BSID-III in 24 month-old children (n=740). PM2.5 was estimated using a validated satellite-based spatio-temporally prediction model. We modeled associations of each of the 3 trimester-average exposures with neurodevelopmental assessment scores, adjusted for potential confounders. Results: In models adjusted by sex of the child, gestational age, birth weight, smoking and mother's IQ, an increase of 1mg/m<sup>3</sup> of PM2.5 predicted a decrease of cognitive and language scores. The most consistent results were in language assessments. At the 24 month follow-up, each unit increase in PM2.5, was associated with a decrease of the language function of -0.38 points (CI95%: -0.77, -0.01). Conclusion: Our findings suggest that language development up to 24 months of age, may be particularly sensitive to PM2.5 exposure during pregnancy.

**001.02.46. Prenatal Exposure to Ambient Air Pollution and Early Childhood Neurodevelopment: A Longitudinal Birth Cohort Study in an Urban Region of the Southeastern U.S.**

Christine Loftus

**Abstract:** Background: Animal studies indicate that air pollution may be neurotoxic, but evidence in humans is limited. We analyzed associations between prenatal air pollution and childhood neurodevelopment in a large birth cohort in Shelby County, TN. Methods: We included mother-child dyads who completed a preschool visit in the Conditions Affecting Neurocognitive Development and Early Childhood (CANDLE) study. Primary outcomes were internalizing and externalizing behavior scores (Child Behavior Checklist) and full-scale IQ score as a measure of general cognition. Prenatal exposures to nitrogen dioxide (NO<sub>2</sub>) and particulate matter less than 10 microns (PM<sub>10</sub>) at maternal residences were estimated using a national annual average universal kriging model (land-use regression with spatial smoothing). We also measured distance to nearest major roadway as a proxy for traffic-related pollution. In regression models, we adjusted for confounding by individual and neighborhood socioeconomic status, maternal IQ, and other determinants of child neurodevelopment; and tested for effect modification by child sex, maternal race, and prenatal nutrition. Results: The study population (N=1009) was predominantly low-income and 69% African American; mean child age at assessment was 4.4 years. Mean NO<sub>2</sub> and PM<sub>10</sub> exposures were 12.9 ppb and 20.9 µg/m<sup>3</sup>, respectively. In fully adjusted models, a 5 ppb increase in prenatal NO<sub>2</sub> was associated with 13% higher externalizing behavior score (95% CI: 0.5, 28%) and 2.8 times higher odds (95% CI: 1.0, 7.9) of an externalizing score above the clinical threshold. Full-scale IQ scores averaged 2.5 points (95% CI: 0.1, 4.8) lower per 5 µg/m<sup>3</sup> increase in PM<sub>10</sub>. We found no statistically significant evidence of associations with road proximity or interaction by demographics or nutrition. Conclusions: Our findings support the hypothesis that air pollution impairs neurodevelopment. We observed the most consistent associations between NO<sub>2</sub> and externalizing behaviors.

## **001.02.47. Early Life Exposure to Fine Particulate Matter and Working Memory and Attention**

Ioar Rivas

*Ioar Rivas<sup>1</sup>, Xavier Basagaña<sup>2</sup>, Marta Cirach<sup>2</sup>, Mónica López-Vicente<sup>2</sup>, Elisabet Suades-Gonzalez<sup>2</sup>, Raquel García-Esteban<sup>2</sup>, Mar Alvarez-Pedrerol<sup>2</sup>, Payam Dadvand<sup>2</sup>, Jordi Sunyer<sup>2</sup>*

*1. King's College London, London, United Kingdom.*

*2. ISGlobal, Barcelona, Spain.*

**Abstract:** Growing evidence has related exposure to air pollution to decelerated cognitive development in children. However, the relevant window of exposure for such an association is yet to be established. The objective of this work was to evaluate the associations between exposures to particulate matter  $\leq 2.5 \mu\text{m}$  (PM<sub>2.5</sub>) at different prenatal and postnatal periods and cognitive function in children to identify important windows of exposure. This study was based on 2,221 children ( $8.5 \pm 0.9$  years old) recruited from 39 schools across Barcelona, Spain (2012). We applied land use regression models to estimate residential PM<sub>2.5</sub> exposure during the prenatal period and the first seven years of life for each participant. Computerized n-back tests to assess working memory (WM) and attentional network tasks (ANT) to assess attentiveness (consistency in response time) and executive function were repeated four times within a year. We used linear mixed effects models with participant and schools as random effects to explore the associations between cognitive development and annual PM<sub>2.5</sub> averages of pre-natal and post-natal exposure, adjusted for relevant covariates. Detrimental periods for WM were identified for the fifth and sixth year of life. An interquartile range (IQR) increase of PM<sub>2.5</sub> at year 6 resulted in a reduction of -4.62 (95%CI: -8.19, -1.04) points in WM. Important differences were observed by sex, with boys having significant negative effects on WM for all the periods except year 2, while no vulnerable period was observed for girls. Periods of significant detrimental effects on the executive function were identified at the prenatal stage and from postnatal year 4 until 7. No significant differences were observed between boys and girls in the attention domains (attentiveness and executive function). Early life exposure to PM<sub>2.5</sub> was detrimentally associated with fundamental cognitive abilities including working memory and executive function.

**Abstract:** Background: Neighborhood deprivation may modify associations between autism spectrum disorder (ASD) and exposure to early life traffic-related air pollution or particulate matter <2.5  $\mu\text{m}$  (PM<sub>2.5</sub>). Methods: We used data from the Study to Explore Early Development to evaluate these associations, which included 674 cases of children with confirmed ASD and 855 population controls. We assessed associations of ASD with roadway proximity, as a marker of traffic-related air pollution, and with PM<sub>2.5</sub> during the entire pregnancy and first year of life. Pregnancy and first year of life PM<sub>2.5</sub> averages were dichotomized at 12.0  $\mu\text{g}/\text{m}^3$ . To characterize neighborhood deprivation, a weighted index was created, based on eight census tract-level socioeconomic status-related parameters. The continuous deprivation index was categorized into tertiles, representing low, moderate, and high deprivation. Logistic regression was used to estimate odds ratios and corresponding 95% confidence intervals for the associations between roadway proximity, PM<sub>2.5</sub>, and ASD. Modification by neighborhood deprivation was assessed on both the additive and multiplicative scales. Results: There was modification by neighborhood deprivation for the association between PM<sub>2.5</sub> during the first year of life and ASD on the multiplicative scale. The association between PM<sub>2.5</sub> exposure and ASD was strongest in regions of high deprivation (OR=2.42, 95% CI: 1.20, 4.86), compared to the moderate (OR=1.21, 95% CI: 0.67, 2.17) or low (OR=1.46, 95% CI: 0.80, 2.65) deprivation groups. Conclusions: These results provide evidence for an association between first year of life PM<sub>2.5</sub> exposure and childhood ASD, and suggest children living in more deprived neighborhoods may be particularly vulnerable to pollution effects. This abstract does not necessarily represent the official positions of the Centers for Disease Control and Prevention or the Environmental Protection Agency.

## O01.02I. New Policy Directions in Exposure Assessment and Environmental Epidemiology

### O01.02.49. Incorporating Regulatory Guideline Values in Analysis of Epidemiology Data

Chris Gennings

Abstract: Fundamental to regulatory guidelines is to identify chemicals that are implicated with adverse human health effects and inform public health risk assessors about "acceptable ranges" of such environmental exposures (e.g., from consumer products and pesticides). The process is made more difficult when accounting for complex human exposures to multiple environmental chemicals. Herein we propose a new class of nonlinear statistical models for human data that incorporate and evaluate regulatory guideline values into analyses of health effects of exposure to chemical mixtures using so-called 'desirability functions' (DFs). The DFs are incorporated into nonlinear regression models to allow for the simultaneous estimation of points of departure for risk assessment of combinations of individual substances that are parts of chemical mixtures detected in humans. These are, in contrast to published so-called biomonitoring equivalent (BE) values and human biomonitoring (HBM) values that link regulatory guideline values from in vivo studies of single chemicals to internal concentrations monitored in humans. We illustrate the strategy through the analysis of prenatal concentrations of mixtures of 11 chemicals and two health effects: birth weight and language delay at 2.5 years. The strategy allows for the creation of a Mixture DF, which is a uni-dimensional construct of single chemical DFs, which focuses the resulting inference to a single dimension for a more powerful one degree-of-freedom test of significance. Based on the application of this new method we conclude that the guideline values need to be lower than those for single chemicals when observed in combination to achieve a similar level of protection as was aimed for the individual chemicals. The proposed modeling may thus suggest data-driven uncertainty factors for single chemical risk assessment that takes environmental mixtures into account. (Support: NIH #R01ES028811 and EU Horizon 2020 #634880)

## **O01.02.50. Development of Exposure Assessments under Amended TSCA**

Nerija Orentas

*Nerija Orentas<sup>1</sup>, Eva Wong<sup>1</sup>, Cathy Fehrenbacher<sup>1</sup>*

*1. OPPT, US EPA, Washington, DC, DC, United States.*

Abstract: On June 22, 2016, the Frank R. Lautenberg Chemical Safety for the 21st Century Act was signed into law thereby amending the Toxic Substance Control Act (TSCA), the Nation's primary chemicals management law. TSCA requires that the risk evaluation process last no longer than three years (with a possible six month extension) and includes, for the conditions of use of the identified chemical, development of a scope, hazard assessment, exposure assessment, and risk characterization. Given the timeframes mandated by TSCA, EPA has been working to develop strategies to more efficiently assess exposures to environmental receptors, consumers, the general population and susceptible populations while using reasonably available information and relying on the best available science. Exposure assessments will rely on the weight of scientific evidence, which will apply a fit-for-purpose systematic review method for exposure data. This presentation will discuss approaches to develop consistency in identifying and refining pathways and routes of exposure among the first ten existing chemicals identified for risk evaluation. Commonalities and differences in the conditions of use, chemical properties, and available information will be presented as well as a path forward for estimating exposure, including the utilization of information on chemical-specific factors such as physical-chemical properties and environmental fate and transport parameters. Examples will highlight some of the strategies in developing and conducting concurrent consumer exposure modeling scenarios for several of the first 10 chemicals undergoing risk evaluation. The views expressed in this abstract are those of the authors and do not represent Agency policy or endorsement

## **001.02.51. Student Science and Environmental Health Literacy on Hopi Lands**

Mary Kay O'Rourke

Abstract: The Hopi Environmental Health Project is funded through the Center for Indigenous Environmental Health Research (CIEHR) at the University of Arizona. When introducing the project to the community, the Tribal Chairman stressed the importance of involving Hopi youth in projects that engender an interest in scientific careers. We conducted two "Student Science" projects during 2017-18 through the Hopi Junior/Senior High School. The projects were conducted in four science classes, and involved students in media specific exposure assessment activities related to radon and arsenic exposure. Prior to initiating the school project, a letter was sent home to parents describing the radon (or arsenic) evaluation and stressing that this was a school science project. During the first class meeting, a 15 minute introductory description of radon (or As) was provided by UA students and faculty. Following the presentation, aid was provided for accurate completion of collection forms (radon or water). Bill-caps were offered to students as incentives. Students took the sampling materials (a sorbent air sampler or water test tubes) home and collected samples. Deidentified samples were returned to school with the collection forms and analyzed at a commercial/university laboratory. Data were returned from the designated lab to the ESC. The ESC prepared individual reports for students and placed them in sealed, addressed envelopes for distribution to the "Student Scientists." The concept of confidentiality was discussed. The ESC consolidated data from the four classes and each student received a data sheet containing all deidentified results for evaluation and reported duration or consumption values for each individual. Analysis involved graphing the data, determining the percent of the group exceeding the analyte standard, and calculating individual and group mean exposures. Evaluation of the outreach indicated that most students enjoyed the project and learned the fundamental concepts.

## **O01.02.52. Development and Demonstration of the Environmental Policy Simulation Tool for Electrical Grid Interventions (Epstein), Version 2.0**

Abstract: Renewable energy and energy efficiency (EE/RE) can have benefits to both climate and public health by reducing emissions of both greenhouse gases (GHGs) like carbon dioxide (CO<sub>2</sub>), and air pollutants (APs), including sulfur dioxide, nitrogen oxides, and fine particulate matter. Benefits of EE/RE have been modeled previously, but scalability can be limited by computational resources necessary to run electrical grid and atmospheric dispersion models. Here, we present and demonstrate EPSTEIN 2.0, a platform that can rapidly assess the health and climate benefits of EE/RE across 10 electrical grid regions in the Continental United States. EPSTEIN 2.0 consists of a rapid electrical grid model that simulates changes in power plant operation and emissions in response to new generation sources or decreased demand from EE/RE measures on that grid. The estimated AP reductions are then fed into a model that estimates the health benefits in monetary terms, using a statistical model for air pollution transport, population and mortality rate data, existing concentration-response functions for the relationship between air pollution and mortality, and standard valuation methods for mortality risk reduction. The GHG emissions reductions are monetized using the Social Cost of Carbon. Our demonstration runs of 200 MW wind, utility-scale solar, and rooftop solar across the Continental U.S. reveal that EE/RE benefits can vary by an order of magnitude across types and locations, for a given capacity of project. This reflects differences in electrical grid mix, downwind populations, and performance of each EE/RE type. Total benefits ranged from \$49 million for 200 MW of wind in the Upper Midwest, to \$6.5 million for 200 MW of wind in California; utility-scale solar ranged from \$23 million in the Mid-Atlantic to \$8.6 million in California; benefits of rooftop solar ranged from \$20 million in the Mid-Atlantic to \$7 million in California.

## **001.02.53. Towards a European Exposure Science Strategy 2030; Bridging the Science and Regulatory Frameworks in Europe**

Yuri Bruinen de Bruin

Abstract: A diverse range of European Union legislation, including REACH, the biocides Regulation, the Sustainable Use of Pesticide Directive, the General Food Law, the Regulation on Medical devices and Construction Products, puts a unique demand on the European exposure science community. In 2017, the European branch of ISES, called ISES Europe, was officially founded promoting the establishment of a highly needed European exposure platform. ISES Europe aims at the integration of exposure science into European regulations and industry practice, and to anchor it in academic research and education, in order to foster innovation and to create a safe and sustainable future for humans and the environment. One of the immediate actions of ISES Europe was to start building a European Exposure Science Strategy with a roadmap 2020 - 2025 - 2030, jointly with all stakeholders that use exposure science in Europe. From 19-20th of June, ISES Europe held its first workshop in Dortmund, Germany, to stimulate discussion and cooperation among ISES Europe members and to encourage the establishment of working groups, building and implementing the Strategy. The Workshop was held along six overarching exposure science themes being 1. data repositories and analytics; 2. regulatory exposure assessment science; 3. building partnerships and collaboration, 4. exposure data production and monitoring; 5. exposure assessment methods and tools; and 6. exposure education and communication. During this presentation the outcomes of the Workshop will be presented including the key indicators of exposure science in Europe along with the state of the art, current scientific developments, important actors, respective boundary conditions and strategies how different sectors and institutions can work together to promote exposure science developments in Europe via partnerships and working groups.

S01.02A. Advances in Air Pollution Exposure Assessment for Population Health Studies in Low and Middle Income Countries: Insights from India and Beyond

**S01.02.01. Pure-Air: A Global Assessment of Household and Outdoor Air Pollution and Cardiopulmonary Disease**

Michael Brauer

Abstract: We are adding an air pollution study (PURE-AIR) to the ongoing prospective urban and rural epidemiological (PURE) cohort, which includes ~225,000 adults aged 35-70 years living in 850 communities in 27 countries. Here, we will describe the comprehensive methods used to estimate outdoor, household and personal air pollution exposures. Outdoor estimates include PM<sub>2.5</sub>, from an existing 1x1km satellite surface, and NO<sub>2</sub>, from a newly created global LUR model. In addition, we are measuring PM<sub>2.5</sub> for 48-hr periods using the UPAS monitor in ~4,500 households and concurrently for ~1,200 individuals. Individuals also wear a silicon wristband to capture organic exposures. To-date we have collected data for 1,400 households and 300 individuals. Data collection will continue for the next 18 months. Preliminary outdoor, household and individual exposure assessment results will be presented and future plans for epidemiological analyses.

## **S01.02.02. Particle Exposure Assessment in Peri-Urban India: Lessons Learned from the CHAI Project**

Cathryn Tonne

*Cathryn Tonne<sup>1</sup>, Margaux Sanchez<sup>1</sup>, Carles Mila<sup>1</sup>, V Sreekanth<sup>2</sup>, Sankar Sambandam<sup>3</sup>, Kalpana Balakrishnan<sup>3</sup>, Julian Marshall<sup>2</sup>*

- 2. University of Washington, Seattle, WA, United States.*
- 3. Sri Ramachandra Medical College, Chennai, India.*

**Abstract:** As part of the CHAI project investigating particle exposure in relation to intermediate cardiovascular outcomes, we modeled four estimates of exposure for a cohort in peri-urban South India. Participants (n~6000) reside in 28 villages with a total area of 8.2km<sup>2</sup> southeast of Hyderabad. Gravimetric 24-hr personal exposure to PM<sub>2.5</sub> and BC was measured on 400 individuals on two occasions; these data were used to develop prediction models of personal exposure for the cohort. Ambient PM<sub>2.5</sub> and BC were measured throughout the study area (21 days, two seasons); these data were used to develop land-use regression (LUR) models of long-term exposure outdoor at residence. Time resolved personal PM<sub>2.5</sub> measurements paired with GPS and wearable cameras were collected on a nested panel (n=40 individuals, six measurement-days). This presentation highlights lessons learned. We compare approaches for estimating exposure and how these estimates compare with more detailed measurements from the panel study. Our results support the potential of predicting personal exposure with high-density time activity data derived from wearable cameras, which is currently feasible only on a relatively small number of participants. Models predicting personal exposure for the full cohort using more limited questionnaire data had moderate performance and showed substantial differences by sex. Distributions of predicted personal exposure were substantially different from exposure estimated by LUR, although agreement was higher in some subgroups. The presentation covers particular challenges in this setting; for example, high within-person (82% men; 78% women PM<sub>2.5</sub>) compared to between-person variability in measured personal exposure. CHAI is a useful example of dense data collection and modeling at the local-scale that can be juxtaposed against larger-scale studies.

### **S01.02.03. Optimizing Air Pollution Exposure Assessment Methods for Pregnant Women: Experiences from the Rural-Urban TAPHE Cohort in Tamil Nadu, India**

Kalpana Balakrishnan

*Kalpana Balakrishnan<sup>1</sup>, Santu Ghosh<sup>2</sup>, Sankar Sambandam<sup>1</sup>, Krishnendu Mukhopadhyay<sup>1</sup>, Naveen Puttaswamy<sup>1</sup>, Thangavel Gurusamy<sup>1</sup>*

*1. Environmental Health Engineering, Sri Ramachandra Medical College & Research Institute, Chennai, India.*

*2. Biostatistics, St Johns Medical College, Bangaluru, Karnataka, India.*

**Abstract:** Background PM<sub>2.5</sub> exposures related to ambient and household air pollution can impact birthweight, but evidence from India is limited. Lack of routinely collected ambient PM<sub>2.5</sub> data and the challenges of conducting personal exposure measurements on pregnant women make it difficult to quantify exposure-response relationships. We report results from the Tamil Nadu Air Pollution and Health Effects(TAPHE) study that developed alternative approaches to estimate pregnancy period exposures for application in exposure-response analyses. **Methods** We followed 1121(602 rural and 519 urban) pregnant women from first trimester until birth to collect exposure and health data. We performed 24-hr kitchen area measurements to cover every trimester and/or season during pregnancy(n=1349) together with living area (n=1164), near household outdoor (n=377) and personal exposure (n=65) measurements in a subset and time-activity recalls at the end of each monitoring period. **Results** The average 24 hr concentrations of PM<sub>2.5</sub> in the kitchen, living and near household outdoor areas were 108.8 µg/m<sup>3</sup>; 65.8 µg/m<sup>3</sup>; and 108 µg/m<sup>3</sup> in rural and 66.3 µg/m<sup>3</sup>; 57.8 µg/m<sup>3</sup> and 57.9µg/m<sup>3</sup> in urban households respectively. The kitchen, living and near outdoor micro-environments contributed to 30%, 54% and 14% of measured personal exposures (adj.r<sup>2</sup>= 82%; ρ= .64 for correlation between measured and time-weighted personal exposures) respectively. This is consistent with time activity profiles, which estimate pregnant women spending ~18-20 hrs indoors. **Conclusion** Indoor PM<sub>2.5</sub> concentrations, from indoor combustion sources but also likely outdoor penetration, contributed the most to PM<sub>2.5</sub> exposure for pregnant women and could serve as a reliable proxy for personal exposures in air pollution and birthweight related exposure-response analyses in India. The recent development of low cost, continuous monitoring PM<sub>2.5</sub> sensors will allow long-term area monitoring to address exposure mis-classification in future studies.

#### **S01.02.04. Towards a National Scale Spatio-Temporal Model for Ambient PM2.5 in India**

Joel Schwartz

*Joel D. Schwartz<sup>1</sup>, Siddhartha Manda<sup>2</sup>*

*1. Environmental Health, Harvard University, Boston, MA, United States.*

*2. Public Health Foundation of India, New Dehli, India.*

Abstract: We report the results of a nation-wide effort to develop a PM2.5 model on a fine spatial and temporal resolution. We will combine WRF-Chem estimates of particle concentrations on a finer spatial scale than GEOS-Chem, updated fire emissions inventories, satellite remote sensing AOD data on a 1 km grid, land use data, and weather data (including PBL height) and train on ground based monitoring using multiple machine learning techniques. Parameter choices will be made using 10-fold cross validation. PM10 data was converted into PM2.5 using a support vector machine on collocated monitors. Nearby monitoring is included as a predictor and missing AOD values will be filled in so that predictions are available for all days and locations. Final models are ensemble weighted averages of the individual models: support vector machine, neural network, gradient boosting, and random forests). Within grid cell land use regression for address specific estimates are done similarly on monitor deviations from cell averages. In preliminary analyses for the greater Dehli area, we find cross validated R2 for annual average PM2.5 of greater than 0.91 except for one year (2011, CV R2=0.72).

### **S01.02.05. Spatiotemporal Prediction of Daily Average Ambient PM2.5 Concentrations at 1 Sq. Km. Grids over Delhi, India, from 2010 to 2016 Using Ensemble Models**

Siddhartha Mandal

*Siddhartha Mandal<sup>1</sup>, Kishore K. Madhipatla<sup>1</sup>, Joel D. Schwartz<sup>2</sup>*

*1. Center for Chronic Disease Control, Gurgaon, India.*

*2. Environmental Health, Harvard School of Public Health, Boston, MA, United States.*

**Abstract:** Introduction: Ambient air pollution in India, with high concentrations of particulate matter, is a major public health hazard. However, detailed spatiotemporal PM2.5 exposure assessment is lacking in India. We modeled daily average ambient PM2.5 concentrations at 1 sq.km. grids in Delhi from 2010-2016, using multiple data sources and ensemble modeling approaches. Methods: A multi-stage modeling was implemented using satellite data, land use data, reanalysis based meteorology and population density. A calibration regression was used to model PM2.5:PM10 to counter the sparsity of ground monitoring data. Next, the relationship between PM2.5 and spatiotemporal predictors was modeled using learners such as gradient boosting models(GBM), support vector regression(SVR) and random forests(RF). Predictions from each learner were combined using a generalized additive model and finally, support vector regressions were used to smooth the spatiotemporal predictions. Results: Monthly median PM2.5 in Delhi ranged from 39-236 $\mu\text{g}/\text{m}^3$  with IQRs between 21-232 $\mu\text{g}/\text{m}^3$ . Average spatial variability across monitoring stations ranged between 21-191 $\mu\text{g}/\text{m}^3$ . Annual average PM2.5 concentrations have increased from 117 to 149 $\mu\text{g}/\text{m}^3$  across the study period. Cross-validated(CV)-R2 for the calibration regression ranged between 0.77 (fall) to 0.88 (monsoon). Average CV-R2 were 0.66(GBM), 0.60(SVR) and 0.67(RF) for the learners and 0.70 for the ensemble averaged (EA) model. Root mean squared errors (RMSE) for EA predictions were in the range 26-61 $\mu\text{g}/\text{m}^3$  with bias (slope of observed vs predicted) ranging between 0.96-1.18 across seasons. Spatial CV-R2 (yearly average) varied between 0.6-0.88, while temporal CV-R2 (daily variability) ranged from 0.52-0.73, across years, showing adequate model performances. Conclusion: Spatiotemporal estimates of PM2.5 concentrations provide comprehensive assessment in high exposure settings and will be used to study the impact of PM2.5 on long and short term health outcomes.

## S01.02B. High-Resolution Metabolomics: A Platform Linking the External and Internal Environment

### S01.02.07. Recent Technical Advancement in High-Resolution Metabolomics

Dean Jones

*Dean Jones<sup>1</sup>*

*1. Department of Medicine, Emory University, Atlanta, GA, United States.*

Abstract: Metabolomics refers to the study of small molecules in biologic systems. Earlier technologies were restricted in sensitivity and only detected hundreds of chemicals, but contemporary ultra-high-resolution mass spectrometry coupled to liquid chromatography, gas chromatography and other separation techniques, show that the metabolome of humans and other species consists of hundreds of thousands of chemicals derived from endogenous metabolism, food, microbial symbionts and infectious agents, and chemicals from environmental exposures. Coupling exposure science measures of exogenous chemicals with high-resolution metabolomics (HRM) for biomonitoring of environmental chemicals and metabolites has considerably facilitated interpretation of low abundance signals, which are often present at three to five orders of magnitude lower abundance than endogenous metabolites. Current HRM methods rely upon multiple technical replicates with advanced instrumentation for separation, ionization and detection, along with data extraction and computational methods. Fourier-transform instruments (e.g., orbitrap MS, Ion-Cyclotron Resonance MS) enable measurement of tens of thousands of chemicals with accurate mass  $m/z$  within 5 ppm mass resolution and mass accuracy. Computational methods and big data tools are being used to curate this extensive number of low abundance signals and connect these chemical signals to metabolic responses, biomarkers of risk and impacts on disease phenotype.

## **S01.02.08. Metabolome Wide Association Study and the Exposome: Linking Exposure to Internal Dose, Biological Response and Disease**

Douglas Walker

*Douglas I. Walker<sup>1</sup>, Vrinda Kalia<sup>1</sup>, Karan Uppal<sup>2</sup>, Shuzhao Li<sup>2</sup>, Gary W. Miller<sup>1</sup>, Dean Jones<sup>2</sup>*

*1. Department of Environmental Health, Emory University, Atlanta, GA, United States.*

*2. Division of Pulmonary, Allergy, Critical Care and Sleep Medicine, Emory University, Atlanta, GA, United States.*

**Abstract:** The metabolic phenotype provides a central measure linking exposure to internal dose, biological response and disease. Use in molecular and environmental epidemiology studies demonstrate application of metabolomic techniques for new insight into how environment contributes to disease; however, key data analyses issues include the need to protect against false discovery, the use of unidentified measures in analysis and strategies to link multiple significant features into common conceptual models for interpretation. In this presentation, we will demonstrate how biological network inference can be applied through a metabolome-wide association framework to delineate exposure biological response in complex organisms and human populations. Applications will include a multi-platform, mass spectrometry-based approach providing in-depth coverage of the exposome and metabolome to characterize a *C. elegans* exposome model, a critically-ill population and patients with primary sclerosing cholangitis. Results from these studies show gas-chromatography with ultra-high resolution mass spectrometry (UHRMS) makes possible detection >75,000 molecular features in plasma, which includes >250 confirmed environmental pollutants. HRM by dual column liquid chromatography with UHRMS detects over 25,000 chemical signals that arise from core nutrient metabolism, lipids, the microbiome, diet-derived chemicals, pharmaceuticals and environmental contaminants, providing measures of biological response, metabolic health and toxicodynamics. Integration of these two platforms and identifying how network topology is associated with metabolic pathway enrichment allows identified and unidentified metabolic signals to be linked to underlying exposure and disease pathobiology. Combined with complementary OMIC measures, such as gene expression, epigenetic and proteomic changes, now makes possible a systems-biology understanding of chemical toxicology and environmental health in humans.

## **S01.02.09. Metabolic Changes Associated with Exposure to Perfluoroalkyl Substances in Women**

Vincent Bessonneau

*Vincent Bessonneau<sup>1</sup>, Roy Gerona<sup>2</sup>, Jessica Trowbridge<sup>3</sup>, Tomas Lin<sup>2</sup>, Ruthann Rudel<sup>1</sup>, Rachel Morello-Frosch<sup>3</sup>*

*3. Department of Environmental Science, Policy and Management, Berkeley School of Public Health, University of California, Berkeley, CA, United States.*

Abstract: Recent epidemiological studies suggest that human exposure to perfluoroalkyl substances (PFAS) may affect metabolic function, inflammation and immunity. To gain further insight about biological effects of PFAS exposures, we explored associations between PFAS and the serum metabolome in adult women. In a cohort of 160 women workers, including firefighters and office workers, from California, we investigated associations of serum PFAS exposures - quantified by liquid-chromatography and tandem mass spectrometry (LC-MS/MS) - with metabolites identified using non-targeted metabolomics analysis using LC combined to time-of-flight mass spectrometry (LC-QTOF/MS) through linear regressions models. After adjusting for age, race/ethnicity, BMI, income and occupation and correcting for multiple hypothesis testing (False Discovery Rate  $\leq 10\%$ ), we observed that several oxylipins, bile acids (BA), steroid hormones and fatty acids were significantly associated with exposures to PFBuS, PFHxS, PFNA, and PFDA, suggesting that exposure to PFAS may contribute to chronic inflammation. To test this hypothesis, we used National Health and Nutrition Examination Survey (NHANES) data to quantify the relationships between serum PFAS and C-reactive protein (CRP) - a well-established marker of inflammation - in adult women, adjusting for age, race/ethnicity, poverty, BMI, and serum cotinine. We found that each doubling in PFDA, EPAH, PFNA, PFOS and PFDoA was positively associated with an increase in serum CRP, confirming some of the metabolomics findings. This study suggests that non-targeted metabolomics is a powerful approach to generate testable hypotheses about possible health effects related to chemical exposures and explore the underlying mechanisms that mediate these relationships.

## S01.02.10. High-Resolution Metabolomics Study of Occupational Exposure to Trichloroethylene

Nathaniel Rothman

*Nathaniel Rothman<sup>1</sup>, Douglas I. Walker<sup>2</sup>, Luoping Zhang<sup>3</sup>, Roel Vermeulen<sup>4</sup>, Laiyu Li<sup>5</sup>, Kurt Pennell<sup>6</sup>, Dean Jones<sup>2</sup>, Qing Lan<sup>1</sup>*

- 1. Division of Cancer Epidemiology and Genetics, National Cancer Institute, Rockville, MD, United States.*

- 5. Guangdong Poison Control Center, Guangzhou, Guangdong, China.*
- 6. Tufts University, Medford, MA, United States.*

**Abstract:** Introduction: Trichloroethylene (TCE) is a common water contaminant and continues to be used in the workplaces of many developing countries. It causes kidney cancer and possibly non-Hodgkin lymphoma and liver cancer. However, the underlying pathophysiology of TCE-induced cancer is not well understood. To evaluate biological responses to TCE, we conducted a cross-sectional molecular epidemiology study of workers exposed to TCE and unexposed controls and applied non-targeted metabolomics analysis. Methods: We studied 80 healthy workers that used TCE and 95 comparable unexposed controls in Guangdong, China. The TCE-exposed workers had a median 8-hour time weighted average personal air exposure of 12 ppm (range: 0.4 to 230 ppm), with almost all workers having exposure under the current U.S. OSHA Permissible Exposure Limit of 100 ppm. Metabolomics analysis of plasma samples was conducted by ultra-high resolution mass spectrometry Results: Metabolic features associated with TCE exposure included known TCE metabolites and additional unidentified chlorinated compounds. TCE exposure was also associated with multiple alterations in endogenous metabolism, including changes in purine catabolism and decreases in sulphur amino acid and bile acid biosynthesis pathways. Specific metabolite associations with TCE exposure included uric acid, glutamine, cystine, methylthioadenosine, taurine and chenodeoxycholic acid, consistent with immunosuppressive, hepatotoxic and nephrotoxic effects that have been related to TCE. There were also correlations between multiple metabolites and additional exposure, immunologic, and nephrotoxic biomarkers that had been measured previously. Conclusion: Untargeted high-resolution metabolomics correlated occupational exposure to TCE with internal dose and metabolic responses, providing new insights into molecular mechanisms of TCE-related disease.

### **S01.02.11. Prospective Study of Untargeted Urinary Metabolomics and Risk of Lung Cancer among Never-Smoking Women in Shanghai, China**

Qing Lan

- 7. Shanghai Cancer Institute, Shanghai, China.*

**Abstract:** Background: Never-smoking Chinese women have a high rate of lung cancer but the etiology is poorly understood. This study is the first to evaluate the untargeted urinary metabolome and risk of lung cancer among never-smoking women in China. Methods: This nested case-control study included 275 never-smoking lung cancer cases and 289 never-smoking controls from a prospective cohort, the Shanghai Women's Health Study, comprising 73,363 Chinese women. Metabolic profiling of urinary chemical features was conducted using ultrahigh-performance liquid chromatography - tandem mass spectrometry (UPLC-MS) and nuclear magnetic resonance spectroscopy. Unconditional logistic regression models were used to estimate the odds ratios (ORs) and 95% confidence intervals (CIs) for the association between each log-transformed metabolite and lung cancer risk, after adjusting for potential confounders. Linear regression was used to estimate associations between the most significant metabolites and dietary factors. Results: Initial analyses found that three UPLC-MS detected urinary metabolites were negatively associated with lung cancer risk with a false discovery rate < 10%: pos\_2.61\_127.0382m/z, neg\_2.60\_369.0408m/z, and pos\_2.61\_184.0325n, which were strongly correlated with each other. The most statistically significant metabolite (pos\_2.61\_127.0382m/z, P = 1.98 x 10<sup>-6</sup>) was identified as 5-methyl-2-furoic acid and was moderately correlated with self-reported usual dietary intake of soy. Increasing tertiles of the metabolite level were significantly associated with reduced lung cancer risk (OR (95%CI): 1.00, 0.52 (0.34-0.80), 0.46 (0.30-0.70, respectively); P-trend = 1.81 x 10<sup>-4</sup>). Conclusions: Our findings suggest that soy foods have a protective effect on lung cancer risk in this population of never-smoking women, and are consistent with a previous report from this cohort using questionnaire-based estimates of soy intake. Further studies are needed to replicate and extend the findings.

## **S01.02.12. Changes in the Blood Metabolome in Relation to 24hr Personal Air Pollution Exposure Measurements: A Panel Study in Four European Countries**

Roel Vermeulen

*Jelle Vlaanderen<sup>1</sup>, Pekka Keski-Rahkonen<sup>2</sup>, Agneta Kiss<sup>2</sup>, Gerard Hoek<sup>1</sup>, Nicole Probst-Hensch<sup>3</sup>, Alessio Naccarati<sup>4</sup>, Andre Amara<sup>5</sup>, Erik van Nunen<sup>1</sup>, John Gulliver<sup>5</sup>, Marc Chadeau-Hyam<sup>5</sup>, Paolo Vineis<sup>5</sup>, Augustin Scalbert<sup>2</sup>, Roel Vermeulen<sup>1</sup>, On Behalf of the Exposomics consortium<sup>5</sup>*

1. *Utrecht University, Utrecht, Netherlands.*
2. *International Agency for Research on Cancer, Lyon, France.*
3. *Swiss Tropical and Public Health Institute, Basel, Switzerland.*
4. *Human Genetics Foundation, Turin, Italy.*
5. *Imperial College London, London, United Kingdom.*

**Abstract:** Background: The peripheral blood might harbor compounds originating from air pollutants and endogenous metabolites influenced by air pollution. Within the Exposomics project high resolution metabolomics was explored as a tool to detect air pollution related changes in metabolic pathways occurring in peripheral blood. Methods: One of the Exposomics studies was a study among a panel of 157 healthy non-smoking adults living in four European cities. We collected three 24-hour personal and ambient exposure measurements of particulate matter (PM<sub>2.5</sub>), PM<sub>2.5</sub> absorbance, and ultrafine particles. Peripheral blood samples were collected in the morning after each exposure measurement and were used for metabolomic profiling by mass spectrometry. All blood samples were analyzed in a single laboratory. We applied univariate mixed-effects models, corrected for multiple testing, to investigate the association between air pollution and high resolution metabolomics. Results: In preliminary analyses we identified associations between the personal measurements of air pollution, including ultrafine particles, with 10 metabolic features at a false discovery rate (FDR) of 5% and with 2029 features at a FDR of 20%. We observed overlap between air pollutants with regards to the associated features. Annotation of the identified features is ongoing. Conclusion: In this study we observed evidence for a potential impact of short term variation in air pollution on metabolic changes in peripheral blood. Considerable between-city differences were observed in both air pollution levels and the metabolome, complicating the identification of those features that are unique to air pollution. We are currently applying a bioinformatics approaches to acquire insight into putatively affected metabolic pathways.

S01.02C. Investigating Chemical Constituents and Exposure Potential in Recycled Tire Crumb Rubber Infill Used in Playing Fields and Playgrounds: State, Federal, and International Governmental Perspectives

**S01.02.13. California Synthetic Turf Study**

*2. OEHHA, CalEPA, Sacramento, CA, United States.*

Abstract: There are over 900 synthetic turf sport fields in California (CA). Public concern about cancer incidents among young athletes, especially soccer goalies, has increased in recent years. The Office of Environmental Health Hazard Assessment of the California Environmental Protection Agency has launched a 4-year environmental health study of the potential health effects associated with synthetic turf fields and playground mats containing recycled tires (i.e., crumb rubber). The aims of the study are to: 1) identify and characterize chemicals and particles released from these fields and playgrounds; 2) evaluate potential human exposures during use of such fields or playgrounds; and 3) assess human health risk from the exposures. The chemical/particle characterization included preinstalled crumb rubber from recyclers, installed crumb rubber from fields, concentrations in air above fields, and targeted laboratory chamber tests. Crumb rubber was sampled from four CA recyclers for initial chemical characterization. A stratified random sampling scheme was applied to recruit fields in various climate regions across CA where infield crumb was sampled. A subset of the fields (n = 35) were included in the detailed environmental exposure testing with both on-field and off-field monitoring. Players performed scripted soccer activities near the on-field monitoring area and testing was conducted both with and without activity on the field. Monitoring was conducted at 1 off-field location and 3 on-field locations near (and downwind from) the active zone and at up to 5 elevations above the field. Monitoring included particulate matter (PM) measurements (number of particles ranging 7 nm to 20 µm; mass of PM<sub>2.5</sub> and PM<sub>10</sub>), metals, volatile and semi-volatile organic chemicals, ozone, temperature (subsurface, surface and above the field), light intensity, humidity and wind speed/direction. This presentation will describe the study protocol and summarize the preliminary data.

## **S01.02.14. Toxicological Research to Assess Bioaccessibility and Biological Effects of Recycled Tire Crumb Rubber Using In Vitro and In Vivo Testing Approaches**

Georgia Roberts

*Georgia K. Roberts<sup>1</sup>, William Gwinn<sup>1</sup>, Matthew Stout<sup>1</sup>, David Crizer<sup>1</sup>, Suramya Waidyanatha<sup>1</sup>, Karen Elsass<sup>2</sup>, Barney Sparrow<sup>2</sup>, Scott Masten<sup>1</sup>*

*1. National Toxicology Program, Apex, NC, United States.*

*2. Battelle Memorial, Columbus, OH, United States.*

**Abstract:** The National Toxicology Program conducted in vitro and 14-day in vivo studies of tire crumb rubber (TCR) to enhance understanding of potential health impacts of exposure to chemicals released from TCR, and to evaluate (1) utility of different experimental models for characterizing toxicity, (2) routes of exposure that may result in systemic exposure, and (3) bioaccessibility of TCR constituents. Multiple lots of fresh recycled TCR were received from California EPA and combined into one test lot for use in these studies. The lot was characterized using microscopy, elemental composition, metal analysis, as well as liquid (LC-MS) or gas chromatography coupled with mass spectrometry. In vitro studies were conducted with human-derived skin, lung, small intestinal and liver cell lines using TCR-conditioned media (TCR-CM). TCR was incubated in cell type-specific culture media for different durations and temperatures followed by sterile filtering to generate TCR-CM for cell exposures. Cytotoxicity was observed with all cell lines, except liver, which was dependent upon concentration as well as the duration and temperature of media conditioning with TCR. Conversely, TCR incubated in PBS or artificial lung fluid was not cytotoxic. Untargeted LC-MS was used to characterize the chemical composition of TCR-CM. In vivo 14-day studies in female B6C3F1/N mice were conducted by administering size-fractionated TCR by oral gavage, dosed-feed or by housing on TCR mixed-bedding. Traditional measures of toxicology testing were evaluated and showed no toxicologically relevant changes by the routes tested. Using a LC-MS metabolomics analysis approach, urine and plasma were evaluated for evidence of exposure. Principle component analysis of untargeted data was unable to differentiate treated and control groups, likely due to low exposure levels and high interanimal variability. Compounds potentially originating from TCR were tentatively identified in urine and plasma from gavage animals.

## **S01.02.15. Moving from a Human Health Risk Assessment of Playing Sports on Rubber Granule Infill in the Netherlands to a Restriction Proposal for Polyaromic Hydrocarbon Content in Rubber Granules in the European Union**

Wouter ter Burg

*Wouter ter Burg*<sup>1</sup>

*1. RIVM, Bilthoven, Netherlands.*

Abstract: The Dutch National Institute for Public Health and the Environment (RIVM) evaluated the health risk of playing sports on synthetic turf pitches with rubber granule infill. To evaluate the health risks of playing sports on rubber granules, it is important to determine which hazardous substances are contained in the granule and to what extent they may be released. Subsequently, it was examined how people playing sports can come into contact with these substances and whether this can lead to health effects. RIVM determined the substances in rubber granule from 100 sports pitches that are representative of the synthetic turf pitches in the Netherlands. The institute further performed three types of laboratory tests to examine the release of substances from the granules, so-called 'migration studies'. In addition, RIVM studied the information available in the scientific literature on substances in rubber granules, their properties and their health effects. The risks for football players were considered virtually negligible, which was later also confirmed by an analyses made by the European Chemicals Agency (ECHA, 2017). However, the current limit values for 'mixtures' supplied to the general public apply to the rubber granules and these limits do not guarantee that risks are controlled. Therefore, the Netherlands in cooperation with ECHA is preparing a restriction dossier. In the restriction dossier under REACH the scope is extended to include exposure of workers (installation and maintenance) and of children at playgrounds with focus on the main driver for risks, i.e. the polyaromatic hydrocarbons (PAHs). Rubber mulches (flakes) may also be used in loose form on playground and these are included in the dossier as well. The restriction proposal submitted by the Netherlands aims at a significantly lower content limit of PAHs in rubber granules, thereby following up on RIVM's recommendation back in 2017.

## **S01.02.16. European Chemical Agency's Perspective: An Evaluation of the Possible Health Risks of Recycle Rubber Granules Used as Infill in Synthetic Turf Fields**

Andreas Ahrens

*Andreas Ahrens<sup>1</sup>*

*1. Registration Directorate, European Chemicals Agency, Helsinki, Finland.*

Abstract: Concerns have been raised in the European Union (EU) whether substances in infill material in synthetic turf fields are causing health risks to players of football (soccer) and other sports. It is estimated that by 2020 there will be 21 000 full size pitches and 72 000 so-called mini-pitches installed in the EU. Most of the infill material used on synthetic turfs is from recycled tyres. ECHA assessed risks of certain prioritised substances to children, professional players, and workers installing or maintaining the fields. The European Chemicals Agency (ECHA) conducted a preliminary evaluation and published its report in February 2017. ECHA did not find a reason to advise people against playing sports on synthetic turfs containing recycled rubber granules as infill material. Exposure to substances assessed caused a very low level of concern, specifically with regard to excess lifetime cancer risk. However, ECHA listed several uncertainties, including the representativeness of the analysed samples and whether other substances were of concern. ECHA made recommendations to take into account the remaining uncertainties, such as the potential need for a restriction to ensure all players on relevant fields have a very low level of concern. This recommendation and their own study led the Netherlands to begin the preparation of a REACH restriction proposal to limit the concentration of polycyclic aromatic hydrocarbons in infill material. The proposal will be evaluated by ECHA's scientific committees for Risk Assessment (RAC) and for Socio-economic Analysis (SEAC) as to whether the proposed restriction would suitably reduce the identified risks and whether the benefits of doing so would outweigh the costs. Based on the opinions, the European Commission, after consulting with the Member States, will then adopt the restriction. Furthermore, the European Commission requested ECHA to also look into the other substances contained in the rubber granules that may be a risk to health.

## **S01.02.17. Perspective from the United States (U.S.) Federal Research Action Plan (FRAP) on Recycled Tire Crumb Rubber Used on Synthetic Turf Playing Fields and Playgrounds**

Annette Guiseppi-Elie

*Annette Guiseppi-Elie<sup>1</sup>*

*1. National Exposure Research Laboratory, US EPA, Durham, NC, United States.*

Abstract: Concerns have been raised by the public, both nationally and internationally, about the safety of recycled tire crumb rubber used in synthetic turf fields and playgrounds. Previous studies have not, in general, provided evidence of adverse health outcomes resulting from exposures to tire crumb rubber infill at synthetic turf fields. Most of the existing published studies were limited in scope and sample size and did not comprehensively evaluate all aspects of exposure associated with the many use scenarios. However, several recent research studies have been initiated to address these limitations, including a recently completed study in the United States that is the basis for this perspective. In 2016, US federal Agencies, specifically, the U.S. Environmental Protection Agency (EPA), the Centers for Disease Control and Prevention/Agency for Toxic Substances and Disease Registry (CDC/ATSDR), and the U.S. Consumer Product Safety Commission (CPSC) launched the Federal Research Action Plan (FRAP) on Recycled Tire Crumb Rubber Used on Synthetic Turf Playing Fields and Playgrounds. CDC/ATSDR and EPA implemented a comprehensive tire crumb rubber characterization study and a pilot-scale exposure characterization study and exposure measurements sub-study that are key components of the study. CPSC plans to use field observations, focus groups, and a national survey of parents and childcare providers to collect information on children's behaviors on playgrounds to identify exposure factors. The presentation will provide insights into completed aspects of the study, including the tire crumb characterization and pilot exposure assessment that are relevant for advancing our knowledge to address potential exposures to tire-derived materials on synthetic turf fields and playgrounds. Also, the presentation will provide a US perspective on the value of this coordinated effort, especially as it relates to other recent research activities globally.

## **S01.02.18. Investigating Chemical Constituents and Exposure Potential in Recycled Tire Crumb Rubber Infill Used in Playing Fields and Playgrounds: State, Federal, and International Governmental Perspectives**

Abstract: Concerns have been raised by the public, both nationally and internationally, about the safety of recycled tire crumb rubber used in synthetic turf fields and playgrounds. Previous studies have not, in general, provided evidence of adverse health outcomes resulting from exposures to tire crumb rubber infill at synthetic turf fields. Most of the existing published studies were limited in scope and sample size and did not comprehensively evaluate all aspects of exposure associated with the many use scenarios. However, several recent research studies have been initiated to address these limitations. This session will include participation from a variety of international governmental researchers. We will use a presentation/panel format where the different speakers will provide opening statements (limited to 15 minutes) on their study perspectives followed by this roundtable discussion where participants will discuss insights gained from each study (guided by a set defined topic areas). The robust discussion should provide valuable information in a global context to attendees on the broad topics of potential exposures and impacts of tire-derived materials used on synthetic turf fields and playgrounds.

## S01.02D. Sound Off for Environmental Noise Research: Milestones in Exposure Assessment and Health Evidence

### **S01.02.19. Noise Exposure Assessment in Europe: Current and Future Challenges**

John Gulliver

*John Gulliver<sup>1</sup>*

*1. Centre for Environmental Health and Sustainability, University of Leicester, Leicester, United Kingdom.*

Abstract: Proprietary software (e.g. CadnaA, SoundPlan,) has long served the needs of undertaking noise assessments for road traffic, railway traffic, aircraft, and industrial noise in Europe as part of strategic noise mapping and exposure studies. The Common Noise Assessment Methods in EU (CNOSSOS-EU), in accordance with the Environmental Noise Directive (END), aims to improve the consistency and comparability of noise assessment results across the EU Member States; CNOSSOS-EU has recently been implemented in software. CNOSSOS-EU also provides an opportunity in international-scale cohort studies for harmonizing exposure assessments, but it brings the challenge, especially for pervasive noise sources such as road traffic, of having detailed information on source emissions over large geographical areas to produce noise estimates at potentially millions of address locations. Open-source road traffic models, including CNOSSOS-EU, have recently been developed with some simplifications to the emissions and propagation models to facilitate exposure assessments in large-scale studies. An overview of the state-of-the-art in noise modelling for exposure studies will be given, including land use regression (LUR) models for noise. Although performance has been shown to be promising (e.g.  $R^2 \sim 0.6-0.8$ ), and in some instances comparable with deterministic noise models, LUR requires spatially distributed noise measurements for model development which are not routinely available. One possibility to assist the adoption of LUR is repeated short-term noise measurements. Examples will be given that compare the performance of LUR with CNOSSOS-EU where spatially dense networks of short-term noise measurements are available. These examples will also show how recent developments to improve the granularity of traffic information on minor roads affects the performance of noise models and distributions of exposures for cohorts.

## **S01.02.20. Noise Exposure Assessment in North America: Past Challenges and Future Opportunities**

Sara Adar

*Sara Adar<sup>1</sup>*

*1. Epidemiology, University of Michigan School of Public Health, Ann Arbor, MI, United States.*

Abstract: Neighborhood noise has been linked to chronic health problems across the life-course, ranging from cognitive and sleep disturbances in children to hypertension and cardiovascular disease in adults. Although noise is a ubiquitous hazard in North America, its population burden has historically not been well characterized due to a lack of exposure estimates. Recently, however, two national prediction models became available for the US: one deterministic model of transportation noise and another empirical model of total (i.e., anthropogenic and natural) noise. While these models may create opportunities for epidemiology, their predictive performance has not been rigorously assessed, especially in complex urban landscapes. This talk presents the results of a validation study of the new US noise models based on nearly 600 daytime, non-rush hour noise measurements collected in one Western, Midwestern, and Eastern city. Predicted transportation (51, 48, 54 dB) and total (51, 55, 55 dB) noise levels were consistently lower than measured levels (63, 61, 74 dB) in Seattle (n=138), Chicago (n=182), and New York City (n=267), respectively. The within-city variability of measured noise levels (SD: 6-7dB; Coefficient of Variation (CV): 9-12%) was similar to that of predicted transportation noise (SD: 6-8 dB; CV: 12-17%) but larger than total predicted noise (SD: 2-3 dB; CV: 4-5%). Both models performed best in Seattle with out-of-sample R<sup>2</sup>s of 0.6 and 0.2 for the transportation and total noise models, respectively. There was poorer predictive performance in Chicago and New York (R<sup>2</sup>s: 0.2 and 0.1 for transportation noise and 0.0 and 0.1 for total noise). Using 20-50 additional measurements collected per city during rush hour, we found R<sup>2</sup>s of similar magnitude (0.0-0.5) though the performance varied by site and model. These findings suggest that the predictive performance of noise models should be carefully considered by location and time when planning future epidemiological research.

## **S01.02.21. Noise and Health in Pregnancy and Birth Outcomes**

Anna Hansell

*Anna Hansell<sup>1</sup>*

*1. Centre for Environmental Health and Sustainability, University of Leicester, Leicester, United Kingdom.*

Abstract: The most recent systematic review of environmental noise and birth outcomes is by Nieuwenhuijsen et al, 2017. It considered 14 studies published up to December 2016 - six aircraft, five road traffic, three total ambient (mainly road) noise. Associations with road traffic noise and low birth weight, preterm birth, and small for gestational age were considered 'low quality' evidence using GRADE criteria (further research is very likely to have an important impact on confidence in the estimate of effect and to change the estimate); while aircraft noise and low birth weight, preterm birth and congenital anomalies was considered 'very low quality' evidence (any estimate of effect is very uncertain). A suite of studies published in 2017 from the Danish national birth cohort considered road traffic noise (Lden) in 1996-2002 for up to 80,000 pregnancies. No significant associations were observed with birth weight, size at birth or congenital anomalies. A study of ~540,000 births in London 2006-10 (Smith, 2017) found no overall associations with road noise after adjusting for air pollutants, but some persisted in highest exposure categories (>65dB Lnight). A French study of ~1500 pregnancies found no association between road noise 2005-9 and preterm birth (Baba-Vasseur, 2017). There are very few studies considering maternal health. In the Danish birth cohort analyses, a 10 dB increase in road noise was associated with increased risk of short- but not long-term increases in time to pregnancy. Positive associations were also seen for hypertensive diseases of pregnancy, but these lost significance after adjustment for air pollution. A study in Korea of 18,165 pregnant women (Min & Min 2017), found an association between night-time aircraft noise during the first trimester of pregnancy and risk of gestational diabetes mellitus. In conclusion, despite a number of recent large studies, the evidence base relating to impacts of environmental noise in pregnancy remains limited.

## **S01.02.22. Noise, Sleep and Health Consequences**

Gunn Marit Aasvang

*Gunn Marit Aasvang<sup>1</sup>*

*1. Department of Air pollution and Noise, Norwegian Institute of Public Health, Oslo, Norway.*

Abstract: There is growing evidence that traffic noise has adverse long-term consequences for health. The recent systematic review commissioned by the WHO revealed increasing evidence for an association between traffic noise and cardiovascular disease, and some evidence for negative impacts on metabolic outcomes such as diabetes and obesity (van Kempen et al., 2018). Proposed mechanisms for these associations have focused on the general stress theory, as well as the impact on sleep as a possible mediator. Sufficient sleep is a prerequisite for good mental and physical health. The most recent systematic review of environmental noise and effects on sleep (Basner and McGuire, 2018) considered the associations with both immediate physiological effects of noise, as well as on self-reported sleep. The quality of evidence according to GRADE criteria, was considered as moderate for cortical awakenings and self-reported sleep disturbance due to traffic noise. For other noise sources, and for other measures of sleep the evidence was of lower quality. In this symposium, an overview of the short- and long-term effects of noise on sleep will be presented. Furthermore, the possible mediating role of sleep on the association between noise and health will be discussed in light of current knowledge, with special emphasis on cognitive and cardiovascular health. References Basner, M. and S. McGuire. WHO Environmental Noise Guidelines for the European Region: A Systematic Review on Environmental Noise and Effects on Sleep. *International Journal of Environmental Research and Public Health*, 2018. 15(3): p. 519. van Kempen, E., et al. ## **S01.02.23. Transportation Noise and Cardio-Metabolic Disease**

Hugh W Davies

*Hugh W Davies<sup>1</sup>*

*1. UBC, Vancouver, BC, Canada.*

Abstract: The link between noise and cardiovascular disease was among the earliest to be examined by researchers interested in the non-auditory effects of noise. While the earliest studies (pre-1980) suffered many limitations, they motivated a body of research in the 1980's and 90's that produced more consistent and increasingly valid findings relating transportation noise and CVD, and produced a biological model. Since then, a number of higher quality studies have probed the roles of different noise sources, and a greater range of outcomes. There is good evidence that noise is an independent risk factor for disease when co-exposure with air pollutants occurs. Increasingly studies have looked at the "intermediate" and other effects of noise in the cardio-metabolic pathway predicted by the model. Still the amount of research being done in this area is relatively low. A 2018 systematic review by the group updating the Environmental Noise Guidelines for the European Region (van Kempen, Cara, Pershagen and Foraster) reviewed evidence for an association between noise and cardiovascular and metabolic effects. They concluded that the most comprehensive evidence was available for road traffic and ischemic heart disease; a meta-analysis of 7 longitudinal studies gave a relative risk of 1.08 (95% CI 1.01-1.15) per 10 dB(LDEN). The most common outcome studied was hypertension but the authors rated the overall quality of evidence "very low". Other outcomes that have been examined include stroke, adiposity, obesity and diabetes. For these outcomes there are much fewer studies; those that exist are of variable quality and their findings are often inconsistent. Nevertheless, there is a plausible biological model linking noise with highly prevalent chronic disease outcomes in humans, so there is a great need for more studies and studies of stronger study designs, e.g. longitudinal, with improved exposure assessment and better control of potential confounding and other biases.

## 001.03A. A Closer Look At Exposures to Flame Retardants

### **001.03.01. Prioritization of Flame Retardants for Human Risk Evaluation Based on Population Levels and Toxicity**

Lisa Melymuk

*Lisa Melymuk<sup>1</sup>, Lola Bajard<sup>1</sup>, Ludek Blaha<sup>1</sup>, Jana Klanova<sup>1</sup>*

*1. Research Centre for Toxic Compounds in the Environment, Masaryk University, Brno, Czechia.*

Abstract: Due to flammability standards, flame retardants (FRs) are widely used in consumer products and building materials. International restrictions on the use of polybrominated diphenyl ethers (PBDEs) have led to their replacement by a plethora of alternative brominated (BFR), chlorinated (CFR) and organophosphate ester (OPE) FRs. PBDEs are broadly detected in human biomonitoring studies, indicating widespread population exposure. However, their replacement by a much larger set of FRs has led to challenges due to a lack of knowledge about physicochemical properties, appropriate biomarkers of exposure, analytical methods, and toxicology. Over 200 FRs are in use today, with a wide range of structures, leading to challenges in how to feasibly evaluate human exposure and assess risk. Through the HBM4EU project (<https://www.hbm4eu.eu/>) we developed a strategy to prioritize FRs for human biomonitoring based on extensive literature review and analysis of exposure and toxicology data, which was then expanded to a broader set of FRs. FRs were categorized based on extent of information on (1) use, (2) human exposure and (3) toxicity. We then ranked the FRs with evidence of toxicity and widespread non-occupational exposure to support further HBM and toxicity evaluation. Of the >200 flame retardants considered, 12 OPEs were identified as having HBM data that suggests significant human exposure, and sufficient evidence of toxicity to warrant concern, including 3 chlorinated OPEs; similarly 1 CFR and 2 BFRs were prioritized based on the same criteria. A further 11 compounds (3 OPEs, 8 BFRs) were highlighted due to a lack of toxicological and HBM data. The structure of the proposed prioritization strategy is such that it can be more generally applied to other compound groups, as the proliferation of the number of chemicals in commerce and with potential for human exposure is not a phenomenon unique to the FRs, but is rather a universal phenomenon of the developments of modern society.

### **O01.03.02. A Study of Flame Retardants in Residential Furniture and Impact on Human Exposure and Flammability Control**

Marilyn Black

*Aika Davis<sup>1</sup>, Debra Harris<sup>2</sup>, Marilyn Black<sup>1</sup>*

- 1. Chemical Safety, Underwriters Laboratories Inc., Marietta, GA, United States.*
- 2. Robbins College of Health and Human Sciences, Baylor University, Waco, TX, United States.*

Abstract: In order to meet flammability requirements, chemical flame retardants (FRs) are often added to consumer products including furniture. In some cases, FR usage is being reduced through elimination or replacement with more benign alternatives. The health risks associated with organohalogen FRs are well documented; exposure to some FRs may lead to health concerns such as cancer, thyroid disruption, delayed mental and physical development, advanced puberty, and reduced fertility. This study examined and compared chemical exposure levels from daily usage and flammability characteristics of residential chair manufactured specifically for laboratory study. All chairs were constructed exactly the same except for the four different FR technologies applied: no FR; application of a textile fire barrier; use of polyurethane foam with an added organophosphorus FR; and use of polyurethane foam manufactured with a reactive FR. The chairs were first measured for VOC and SVOC emissions, inside an environmentally controlled chamber, for inhalation, ingestion, and dermal exposure levels. Following chemical studies, the chairs were burned in a controlled fire laboratory to measure flammability parameters. Results show differences in FR exposure and flammability performance among the different chair types. Added FRs were detected in some of the environmental samples during the environmental chamber exposure measurements. The fire barrier technology had the greatest impact in suppressing furniture combustion. With the amount of FRs added to the constructed chairs, the chemical FRs did not show a measurable fire suppression advantage over chairs without any FRs. The study also shows the presence of other chemicals that should be considered in evaluating chemical exposure risks. This study provides scientific data to assess chemical exposure risks and flammability from furniture. The results will contribute to policy discussion on flammability regulations and product safety.

### **O01.03.03. Exposure to Brominated and Organophosphate Ester Flame Retardants in U.S. Childcare Environments: Effect of Removal of Flame-Retarded Nap Mats on Indoor Levels**

Amina Salamova

*Amina Salamova<sup>1</sup>, William A. Stubbings<sup>1</sup>, Kevin Romanak<sup>1</sup>, Marta Venier<sup>1</sup>, Maia Thomas<sup>2</sup>, Erika Schreder<sup>2</sup>*

*1. Indiana University, Bloomington, IN, United States.*

*2. Toxic Free Future, Seattle, WA, United States.*

**Abstract:** Nap mats are a significant item in childcare settings used for children naptime. Typically, they are one- to two-inch thick mattresses made of polyurethane foam encased in a vinyl cover. Childcares that serve young children in full-day programs generally use, and store, one nap mat for each child. For this study, we conducted an intervention, replacing flame-retarded nap mats with flame-retardant-free mats, and measured concentrations of flame retardants in indoor air and dust before and after replacement. Seven childcare centers in Seattle, USA, were recruited to participate in the study using the following criteria: regular use of nap mats, serving low-income families, and minimal presence of other foam-containing items. Foam from existing in-use nap mats from each center was analyzed to confirm the presence of flame retardants. Foam and fabric from replacement mats was also analyzed for flame retardants to identify flame-retardant-free products. Existing mats were replaced with flame-retardant-free mats or cots in six centers. The predominant FRs found in dust and indoor air were 2-ethylhexyl tetrabromobenzoate (EHTBB) and tris(1-chloro-2-propyl) phosphate (TCIPP), respectively. Naps mat samples analyzed from five of the seven centers contained a Firemaster<sup>®</sup> mixture, while one mat was predominantly treated with tris(1,3-dichloroisopropyl) phosphate (TDCIPP) and the other contained no detectable target FRs. After replacement, there was a significant decrease ( $p = 0.03-0.09$ ) in median dust concentrations for bis(2-ethylhexyl) tetrabromophthalate (BEHTBP), EHTBB, tris(4-butylphenyl) phosphate (TBPP), and TDCIPP with reductions of 90%, 79%, 65%, and 42%, respectively. These findings suggest that the nap mats were an important source of these FRs to dust in the investigated childcare environments and that a campaign of swapping out flame retarded mats for FR-free ones would reduce exposure to these chemicals.

#### **001.03.04. Temporal Trends in Serum Polybrominated Diphenyl Ether Concentrations in the Australian Population, 2002-2013**

Lesia Aylward

*Leisa-Maree Toms<sup>1</sup>, Andreas Sjodin<sup>2</sup>, Peter Hobson<sup>3</sup>, Fiona Harden<sup>4</sup>, Lesia Aylward<sup>5</sup>, Jochen Mueller<sup>6</sup>*

- 1. Queensland University of Technology, Brisbane, QLD, Australia.*

- 5. Summit Toxicology, LLP, Falls Church, VA, United States.*
- 6. Queensland Alliance for Environmental Health Sciences, University of Queensland, Brisbane, QLD, Australia.*

Abstract: In Australia, systematic biomonitoring of persistent organic pollutants (POPs) in pooled serum samples stratified by age and sex has occurred every two years between 2002/03 and 2012/13. Multiple regression modeling on log<sub>10</sub>-transformed serum pool concentrations of BDEs 47, 99, 100 and 153 and on the sum of these ( $\Sigma$ 4PBDE) was conducted to examine trends by sex and time since baseline, stratified by age group. Temporal trends were age- and congener- specific, with the largest changes per year of observation in the 0-4 year old group, with  $\beta$  (SE) = -0.098 (0.013) for log<sub>10</sub>BDE47; -0.119 (0.012) for log<sub>10</sub>BDE99; -0.084 (0.014) for log<sub>10</sub>BDE 100, and -0.053 (0.013) for log<sub>10</sub>BDE153, all  $p < 0.001$ . Adults over age 16 showed much smaller decreasing temporal trends for BDE47 and BDE99, no significant changes in BDE100, and, for the oldest age groups, slight increases in BDE153. As a result,  $\Sigma$ 4PBDE concentrations were stable over the entire time period in adults older than 16. Concentrations of each BDE in pools from females aged 31-60 were significantly lower compared to males. Relative proportions of BDE47 declined, while BDE153 accounted for a greater share of  $\Sigma$ 4PBDE over time. Whereas previously we saw a large elevation in the youngest age groups compared to older children and adults, this is no longer the case. This may be due to a decline in infant and toddler exposures in the indoor environment as use of PBDEs in consumer products has been phased out, suggesting temporal changes in the relative sources of exposure for young children in Australia.

### **O01.03.05. The Association of Urinary Phosphorous-Containing Flame Retardant Metabolites and Self-Reported Personal Care and Household Product Use among Couples Seeking Fertility Treatment**

Mary Ingle

*Mary E. Ingle<sup>1</sup>, Lidia Minguéz-Alarcón<sup>2</sup>, Courtney Carignan<sup>3</sup>, Craig M. Butt<sup>4</sup>, Heather Stapleton<sup>4</sup>, Paige Williams<sup>2</sup>, Jennifer Ford<sup>2</sup>, Russ Hauser<sup>2</sup>, John Meeker<sup>1</sup>*

*2. Harvard, Boston, MA, United States.*

*3. Michigan State University, Lansing, MI, United States.*

*4. Duke University, Durham, NC, United States.*

**Abstract:** Background Phosphorous-containing flame-retardants (PFRs) are widely detected. Increased exposure to PFRs has been associated with disrupting the endocrine and reproductive systems of animals and humans. While primarily used as a flame retardant, some PFR chemicals are also used as a plasticizer and have been detected in nail polish. Methods A subset of 230 women and 229 men from an existing longitudinal cohort were recruited from Massachusetts General Hospital fertility clinic between 2005 and 2015. At each visit, participants completed a 24-hour recall questionnaire of personal care product (PCP) and household product (HP) use. Metabolites [bis(1,3-dichloro-2-propyl) phosphate (BDCIPP), diphenyl phosphate (DPHP), isopropylphenyl phenyl phosphate (ip-PPP), tert-butylphenyl phenyl phosphate (tb-PPP) and bis(1-chloro-2-propyl) phosphate (BCIPP)] were measured in urine (1-5 samples; n=638 female, n=335 male). Associations among products and metabolites were assessed using multivariable generalized mixed models, adjusted for specific gravity, age, BMI, smoking, education, and season. Results: BDCIPP, DPHP, and ip-PPP were highly detected (66-89%). Concentrations were mostly higher among females and correlations among couples were weak ( $r \leq 0.31$ ). Moisturizer (60%), nail polish remover (77%) and nail polish (134%) were associated ( $p < 0.05$ ) with an increase in DPHP while concentrations of ip-PPP increased 21-27% with conditioner, cosmetics, deodorant and hair product use in females. In males, mouthwash and vinyl glove use were associated with an increase (31 and 92%) in DPHP. Conclusions: PFR metabolites were highly detected, although concentrations were higher among females. Weak correlations and inconsistent associations between females and males suggest that PFRs may also be used as a plasticizer in consumer products. Our findings suggest nail polish use may contribute to internal DPHP exposure. Further research of PFR compounds in PCP and HP is necessary.

### **001.03.06. Intervention to Reduce Gymnast Exposure to Flame Retardants: A Case Study**

Courtney Carignan

*Courtney Carignan<sup>1</sup>, Robin E. Dodson<sup>2</sup>, Heather Stapleton<sup>3</sup>*

*1. Michigan State University, East Lansing, MI, United States.*

*2. Silent Spring Institute, Newton, MA, United States.*

*3. Duke University, Durham, NC, United States.*

Abstract: We previously reported that gymnasts can have high, quasi-occupational, exposures to flame retardants (FRs) due to their use in gymnastics safety equipment such as the loose foam pit, which is used by gymnasts to learn new skills safely. Such exposures are likely widespread, as we previously identified FRs in the majority of foam samples collected from gyms across the U.S. and it is reported that 4-5 million kids and teens train at U.S. gymnastics clubs. Therefore, our objective in this case study was to quantify changes in gymnast exposure to FRs following an intervention that replaced the foam pit using FR-free foam. We collected samples from the foam pit as well as hand-wipe samples from 15 collegiate gymnasts before and after a gymnastics practice both pre- and post-intervention (n=42 hand-wipe samples total). Samples were analyzed for FRs using GC/ECNI-MS and GC/EI-MS. FRs identified in samples from the foam pit included tris(1,3-dichloro-2-propyl) phosphate (TDCIPP) and the Firemaster 550<sup>®</sup> mixture which includes 2-ethylhexyl-2,3,4,5-tetrabromobenzoate (EH-TBB), bis(2-ethylhexyl)-2,3,4,5-tetrabromophthalate (TBPH), and triphenyl phosphate (TPHP). When concentrations of these FRs in hand-wipes were summed we observed a 1.4-fold increase in the GM concentration from before to after practice pre-intervention (p=0.01, n=10) whereas only a 0.4-fold increase was observed post-intervention (p=0.16, n=10). These differences were more pronounced among those who reported using the foam pit, with a 3.5-fold increase pre-intervention (p=0.06, n=5) and a 1-fold increase post-intervention (p=0.03, n=7). The distribution of these differences declined from pre- to post-intervention (p=0.01). Overall, these findings indicate that replacing a foam pit using FR-free foam can substantially reduce gymnast exposure to FRs used in foam.

## 001.03B. A Global Look at Lead Exposures

### **001.03.07. Environmental Justice Analyses May Hide Inequalities in Indigenous People's Exposure to Lead in Mt Isa, Australia**

Abstract: Elevated blood lead levels (BLLs) in children have been recorded in the city of Mt Isa due to lead emissions from the nearby mining and smelting facilities. Several studies have found that Indigenous children have had significantly higher geometric mean BLLs than non-Indigenous children, but there is a lack of recent BLL data to determine if Indigenous children in Mt Isa are disproportionately exposed to lead pollution. Environmental Justice studies have demonstrated cases of disproportionate exposure to pollution between communities by calculating the statistical relationships between the spatial distribution of ethnic communities and the concentration of pollution. Other epidemiological studies have found a significant association between children's BLLs and the concentration of lead in soil where they live. Taken together these findings suggest that there may be a significant correlation between soil lead concentration and the distribution of Indigenous children and their families in Mt Isa. To test for this correlation, we collected and analysed soil samples from 49 of the 51 census Statistical Area 1s (SA1s) in Mt Isa and measured the correlation between the soil lead concentration and the percentage of residents living in each SA1 who were of Indigenous status. Using linear regression and Kendall's tau, we found no significant correlations between any measure of Indigenous status with soil lead concentration, and little evidence of a relationship between socio-economic status (SES) and soil lead concentration. The results of our study indicate that Indigenous and low-SES residents are not disproportionately likely to live in areas with elevated concentrations of lead in soil, indicating that other factors are responsible for elevated BLLs. More research and policy attention should be given to risk factors that may be exacerbating the risk of exposure to lead in air or soil for low-SES children, including Indigenous children.

### **001.03.08. Blood Lead Levels in Children Aged 0 to 6 Years in China: A National Survey**

Chong-Huai Yan

*Chong-Huai Yan<sup>1</sup>*

*1. Ministry of Education-Shanghai Key Laboratory of Children's Environmental Health, Xinhua Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China.*

**Abstract:** Background : Lead exposure is a major environment-related disease that severely endangers child health. However, the magnitude of lead exposure among children in China remains unclear at the national level. We conducted a national survey of blood lead levels in children aged 0 - 6 years. Methods :From May 2013 to March 2015, we used a multi-stage clustered random sampling approach to select 90 districts/counties in 15 provinces across the country. Parents were interviewed, and the blood lead levels in children were tested using graphite furnace atomic absorption spectrometry. Findings: A total of 31,373 children with valid samples were included. The median and geometric mean blood lead levels were 26.4 and 26.7µg/L, respectively. The geometric mean blood lead level of children in Shanghai was the lowest (18.8µg/L), and that in Guangdong was the highest (33.7µg/L). The blood lead level of the children in the central region was the lowest (25.5µg/L) compared with the eastern region (26.6µg/L) and the western region (27.3µg/L). The geometric mean blood lead level of the children in large cities (24.2µg /L) was lower than that of the children in smaller cities (27.4µg /L) and rural areas (27.5µg/L). Boys had a higher lead level than girls (27.2 vs. 25.9µg/L,  $p<0.0001$ ). Children aged 36-84 months had a slightly higher lead level than children aged 0-36 months (25.7 vs. 27.9µg/L,  $p<0.0001$ ). Interpretation: The blood lead levels in children aged 0-6 years in China showed a dramatic decline compared with the past few decades. The blood lead levels of children were the lowest in the central region and among urban children in big cities. The blood lead levels of boys were higher than those of girls, and the lead levels were much higher in 36- to 84-month-old children than in 0- to 36-month-olds.

### **001.03.09. Three Decades of Lead Poisoning Prevalence in Mexico City Children: 1988 to 2015**

Ivan Pantic

Abstract: Epidemiologic studies may be the best approach to estimate lead exposure of the general population in countries where there is no national surveillance of blood lead levels (BLL). The United States Centers for Disease Control and Prevention (CDC) established in 2012 a reference level of 5 µg/dL to identify children with elevated BLL which represents the 97.5 percentile of children ages 1-5 years. We used data from five birth cohorts from the same health services in Mexico City, including the Early Life Exposure in Mexico and Environmental Toxicants (ELEMENT, 4 distinct studies), that enrolled children and mothers and followed them longitudinally. We estimated the time trends in the prevalence of Mexico City children with BLL ≥ 5 µg/dL. We focused on BLL of children 1 to 5 years old between 1988 and 2015. A total of 2,562 children contributed with 7,557 samples, with a maximum of one sample per child per year. The median blood lead levels decreased from 14.5 µg/dL in 1988 to 1.6 µg/dL in 2015. In 1988 the prevalence of children with BLL ≥ 5 µg/dL was 100%. In 1997, when lead was completely eliminated from the gasoline in Mexico City, it was 86.3% and ten years later, in 2007, 32.8%. In the period from 2010 to 2015 the prevalence fluctuated between 10.8% and 4.2%, suggesting that the decline has plateaued. 30 years after eliminating leaded gasoline, remarkable progress has been made in reducing childhood lead poisoning, but there is still a high prevalence of children in Mexico City with elevated blood lead levels. Further public health interventions as well as a surveillance program are needed in order to further reduce lead, provide national estimates of blood lead levels in Mexico and to identify sources of exposure.

### **O01.03.10. Bone Lead Associations with Blood Lead, Kidney Function, and Blood Pressure among U.S. Lead-Exposed Workers in a Surveillance Program**

Vaughn Barry

*Vaughn Barry<sup>1</sup>, Andrew C. Todd<sup>2</sup>, Kyle Steenland<sup>1</sup>*

*1. Department of Environmental Health, Emory University Rollins School of Public Health, Atlanta, GA, United States.*

*2. Department of Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, NY, United States.*

**Abstract:** Background: Measurements of lead in bone represent cumulative exposure which, in many studies, has been more strongly associated with lead effects than blood lead (BL), which represents recent exposure. Aim: Determine whether maximum BL in the past is correlated with current bone lead and compare associations of bone lead with kidney function and blood pressure (BP) among workers. Methods: Adult men in a lead surveillance program living within 200 miles of New York City were enrolled during 2016-2017. Participants had tibia lead measured via K-shell X-ray fluorescence, BP taken, and blood drawn to measure BL and estimated glomerular filtration rate (eGFR). Maximum past BL was obtained from occupational surveillance programs (mean year first BL 1997). eGFR was calculated using serum creatinine and cystatin C. Multivariable linear and logistic regression models were used to determine associations with bone lead. Systolic and diastolic BP models excluded participants taking BP medicine. Results: Among 211 participants, median (interquartile range) bone lead, current BL, and maximum past BL were 13.8 (9.4-19.5) mg of lead per gram of bone mineral, 2.5 (1.5-4.4) mg/dl, and 29.0 (14.0-38.0) mg/dl, respectively. Maximum past BL, but not current blood lead, significantly predicted current bone lead in adjusted analyses ( $p < 0.0001$ , model R-square=0.27). In adjusted models, bone lead was moderately associated with low eGFR (bone lead odds ratio and 95% CI per 10 mg of bone lead for  $eGFR < 60 = 1.34 [0.97-1.87]$ ; the regression coefficient and p-value for continuous eGFR was also significant [ $p = 0.05$ ], model R-square=0.29). Bone lead in adjusted analyses was associated with increased systolic BP (regression coefficient=0.36,  $p = 0.02$ , model R-square=0.16). There were no associations between current blood lead and eGFR or BP. Conclusion: Bone lead was significantly correlated with past maximum BL and was associated with modest decreases in eGFR and increases in systolic BP.

### **O01.03.11. Point-Of-Care Analysis of Manganese and Lead in Water**

**Abstract:** Metals are ubiquitous in the environment and have long been recognized to pose significant threat to human health. Blood lead (Pb) has been consistently associated with deficits in IQ and academic achievement; manganese (Mn) has been associated with Parkinson's disease or neurological malfunction in children. Current approaches for determining exposure (e.g., ICP-MS or AAS) require extensive labor, equipment, and long turnaround times. A relatively swift assessment of heavy metal exposure that ultimately reduces costs and turnaround times would benefit pediatric public health nationally and internationally. Our long-term goal is to develop a portable system with disposable sensors to move analysis from the laboratory to the clinical setting. Our sensor is based on electrochemical determination of Mn and Pb, and contains platinum working and auxiliary electrodes, and an electroplated Ag/AgCl reference electrode. An advantage of this sensor is the small size (~10mm on side), the need for only a few drops (~10 $\mu$ L) of sample, and rapid analysis (~10min). We are using cathodic stripping voltammetry for Mn, and anodic stripping voltammetry for Pb. The sensor operational parameters, such as deposition time and potential, supporting electrolyte and pH, were optimized for each metal. The sensor achieved detection limits of 0.9ppb for Mn and 4.4ppb for Pb. We conducted a pilot study to determine Mn and Pb in well drinking water samples from different sites in Marietta, OH (which is home a ferromanganese processing plant). Analyses were performed by diluting samples 2 $\times$  with pH5.5, 1M acetate buffer, and adding three spikes for the standard addition method. In these samples (n=7), the mean accuracy was 89% with mean precision of 97%, as compared with ICP-MS "gold standard" measurement by a reference lab. Ultimately, the sensor system could act as a simple, fast and low-cost alternative for point-of-care applications in local clinics or resource-limited settings.

### **001.03.12. Lead Exposure Biosensors from Epigenome-Wide Blood DNA-Methylation in Adults**

Elena Colicino

*Elena Colicino<sup>1</sup>, Marianthi-Anna Kioumourtzoglou<sup>2</sup>, Allan Just<sup>1</sup>, Ana Navas-Acien<sup>2</sup>, Pantel Vokonas<sup>3</sup>, Robert Wright<sup>1</sup>, Joel D. Schwartz<sup>4</sup>, Andrea Baccarelli<sup>2</sup>*

*2. Columbia University, New York, NY, United States.*

*3. Boston University School of Public Health, Boston, MA, United States.*

*4. Harvard TH Chan School of Public Health , Boston, MA, United States.*

**Abstract:** Background: Lead is a ubiquitous toxicant with a numerous chronic health effects. Between 2002-2011 more than 11,000 U.S. adults suffered acute lead-poisoning (>5 µg/dL). Acute symptoms are often misinterpreted or unrecognized and for this reason blood lead levels are likely under tested. Patella bone lead-a reliable measure of chronic cumulative exposure- is a highly specialized measure, requires exposure to X-radiation, and is available only in a small number of centers. Objective: To develop novel and safe biosensors reflecting individual current (blood) and cumulative (patella) lead exposure using whole blood DNA methylation profiles. Methods: We developed and tested two biosensors using data from epigenome-wide whole blood DNA methylation levels in men of the Normative Aging Study (NAS) cohort via the Illumina 450K bead chip. We selected methylation sites most responsive to lead exposure via robust regressions-adjusted for socio-demographic, life-style information and white cell proportions-and constructed the final biosensors using elastic nets. We used 10-fold cross-validation to test the biosensors. Results: Most NAS participants were exposed to relatively low levels of lead (median blood lead (Interquartile-range IQR) = 3 (3) µg/dL, median patella bone lead (IQR) 25.2 (20.2) µg/g). The elastic nets selected 1177 and 599 sites within the epigenome with non-null coefficients to estimate the blood biosensor and bone biosensor, respectively. Among the selected sites of both biosensors, only eight sites overlapped. The biosensors estimated lead levels that were highly correlated with actual values of blood (R<sup>2</sup>=0.92) and bone lead (R<sup>2</sup>= 0.96). Discrepancies were found mostly at extreme lead levels (in blood>7.5µg/dL, in bone>50µg/g). Conclusions: Our epigenetic lead biosensors are novel tools of measuring individual lead levels and may help identify lead-poisoning and its health impacts when available.

## 001.03D. Effects of Heat Waves

### **001.03.19. Heat Wave Effects on Mortality and Years of Life Lost in a Dry Region of Iran (Kerman) during 2005-2016**

Narges Khanjani

*Omid Aboubakri<sup>1</sup>, Narges Khanjani<sup>1</sup>, Younes Jahani<sup>1</sup>, Bahram Bakhtiari<sup>2</sup>*

*1. Epidemiology and Biostatistics, Kerman University of Medical Sciences, Kerman, KERMAN, Iran (the Islamic Republic of).*

*2. Water Engineering Department, College of Agriculture, Shahid Bahonar University of Kerman, Kerman, KERMAN, Iran (the Islamic Republic of).*

**Abstract:** Introduction: The present study was conducted to compare the added effect of heat waves on mortality and years of life lost in Kerman, Iran during the years 2005-2016. Methods: Daily mean temperature and a combination of intensity and duration were used in order to define heat waves (90, 95 and 98th percentile and  $\geq 2, 3,$  and 4 consecutive days). YLL, considering discount rate, was calculated according to Iran's life table. In order to investigate the effect of heat waves in different lags and its cumulative effect on mortality and YLL, Poisson and linear models within distributed lag nonlinear models were used respectively. A maximum lag of 14 days was considered. The best model was selected based on Akaike Information Criteria. The model was adjusted for air pollutants, public holidays, days of the week and humidity. Results: The average daily mortality and YLL were  $10.54 \pm 4.31$  deaths and  $175.58 \pm 91.39$  years respectively. They were mostly related to men and were higher in heat waves matching a definition of above the 98th temperature percentile and  $\geq 2$  days, than others. Except heat waves defined as 98th percentile and  $\geq 4$  days, the effect of heat waves on mortality and YLL were the highest at Lag 0. The cumulative relative risk of total mortality was significant except in heat waves above the 90th percentile. The cumulative effect of heat waves on the total YLL was significant only above the 98th percentile. Men over 65 years old were the most vulnerable group in term of both mortality and YLL. Conclusion: Heat waves with temperatures above the 98th percentile for all three durations had a significant effect on both YLL and mortality in Kerman, Iran.

### **O01.03.20. Heat-Related Mortality Trends and Human Adaptation Response to Climate Warming in Spain: A 30-Year Observational Study by Sex and Cause of Death**

Joan Ballester

*Hicham Achebak<sup>2</sup>, Daniel Devolder<sup>2</sup>, Joan Ballester<sup>1</sup>*

*1. Barcelona Institute for Global Health (ISGlobal), Barcelona, Catalonia, Spain.*

*2. Center for Demographic Studies (CED), Barcelona, Spain.*

**Abstract:** Background. Anthropogenic greenhouse gas emissions have increased summer temperatures in Spain by nearly one degree Celsius over the last three decades. However, little is known about the extent to which the associations between heat and human mortality have been modified due to societal adaptation. We investigate whether warmer summers are associated with an upward trend in excess mortality attributable to heat or, on the contrary, this trends has been counterbalanced by an adaptive response of the population. Methods and findings. We analyzed a large dataset from 46 capital cities in Spain for the summer months between 1986 and 2015, which included daily temperatures and number of deaths from circulatory and respiratory causes by sex. We applied standard quasi-Poisson regression models, controlling for seasonality and long-term trends, and estimated the temporal variation in heat-related mortality with time-varying distributed lag nonlinear models. The results pointed to a strong and progressive reduction during the study period in relative risks of cause-specific and cause-sex mortality across the range of summer temperatures, which led to downward trends in overall heat-attributable deaths. Conclusions. The summer warming observed during the last decades in Spain has been completely counterbalanced by an adaptive response of the population, which has led to a sustained downward trend in heat-related human mortality. This reduction occurred in parallel with a decline in the gender vulnerability gap between men and women. Despite these advances, the risk of death remained high for respiratory diseases, and particularly in the case of women.

## **O01.03.21. Forty Years of Heat Waves in France: A Tale of Climate Change and Health**

Mathilde Pascal

*Mathilde Pascal<sup>1</sup>, Vèrène Wagner<sup>1</sup>, Magali Corso<sup>1</sup>, Karine Laaidi<sup>1</sup>, Alain Le Tertre<sup>1</sup>*

*1. Santé publique France, Saint Maurice, France.*

**Abstract:** Introduction: Heat waves are the most emblematic health risk directly influenced by climate change. This study documents changes in heat waves' characteristics between 1974 and 2013 in France, the associated mortality impacts, and the influence of the national heat prevention plan developed in 2004. Method: Daily temperature and mortality data were collected for the 96 metropolitan French departments. The French heat warning system definition was used to identify heat waves. Each heat wave was characterized by its duration, intensity (compared to warning thresholds), and associated excess mortality (compared to the previous years). We investigated if the association between mortality rates and intensity changed after 2004. Results: 921 heat waves were identified. The population exposed to dangerous heat waves has doubled between 1974-1983 and 2004-2013. There is no increasing trend in intensity. The mean intensity of the 2003 heat waves was 2-fold higher than any other event, underlying its exceptionality. We observed 31,661 [27,110: 36,188] excess deaths during the 921 heat waves, 45% before 2003, 48% in 2003, and 7% after 2003. The relative risk of mortality for a 1°C increase in intensity was 1.12 [1.11:1.14] before 2003, and 1.13 [1.10:1.17] after 2003. Discussion : Changes in frequency, geographic and temporal spread of heat waves are already observed in France, increasing the exposure of the population. Results do not support an influence of the heat prevention plan on the intensity-mortality relationship at the department scale. The year 2003 remains a unique year with no historical equivalent, and is an example of what may occur in the future. The health impacts of heat waves are the main observable health impacts of climate change. Developing easy-to-understand indicators to observe and describe their evolution is an asset to promote adaptation and mitigation policies.

### **O01.03.22. Quantifying the Mediating Effects of Ozone in the Relation between Heat Waves and Years of Life Lost**

Tarik Benmarhnia

*Tarik Benmarhnia*<sup>1</sup>

*1. Family Medicine and Public Health, UCSD, La Jolla, CA, United States.*

Abstract: Some studies have proposed that the role of ozone in studies of temperature and mortality is a causal intermediate that is affected by temperature and that can also affect mortality. However, no study has empirically investigated the mediating effects of ozone in the relationship between hot temperatures and health. We propose to use state-of-art causal mediation analysis to decompose the total effect between heat (using various heat waves definitions) and years of life lost (YLL) into: i) controlled direct effects (CDE) which represent the effect of temperature without ozone; and ii) natural indirect effects (NIE) that represent the specific mechanisms involving ozone formation during hot days and including primary pollutants emissions (i.e. NO<sub>2</sub>). We also conducted a 4-way decomposition to consider mediation and effect measure modification simultaneously. The study was conducted in Montreal for the 1990-2010 period. The total effect between heat waves and YLL was 362.54 (95%CI: 272.98; 452.09). We found a CDE of 312.87 (95%CI: 212.80; 412.94) and a NIE of 49.67 (95%CI: 4.44; 94.89). We did not find any evidence supporting an interaction between ozone and heat. The mediating effect of ozone in the impact of heat waves on YLL was relatively small (~14%). Studying such mechanisms in various locations is crucial as during heat waves, public health efforts are geared towards reducing exposure to heat but do not typically take into account exposure to ozone.

### **O01.03.23. Assessing the Impact of Cold and Heat Waves on Physical Activity in a Sub-Tropical Urban Population**

Janice Ho

*Janice Y. Ho<sup>1</sup>, Emily Chan<sup>1</sup>, Phoenix Mo<sup>1</sup>, Holly Lam<sup>2</sup>*

*1. The Jockey Club School of Public Health and Primary Care, The Chinese University of Hong Kong, Hong Kong SAR, Hong Kong.*

*2. Collaborating Centre for Oxford University and CUHK for Disaster and Medical Humanitarian Response (CCOUC), The Chinese University of Hong Kong, Hong Kong SAR, Hong Kong.*

**Abstract:** Background: Extreme temperatures are increasing due to climate change, however research of their impacts on health behaviour are rare. While cold winter temperatures have been identified as a barrier to physical activity, an increase of extremely hot temperatures due to climate change may also potentially affect frequency of physical activity. This study aims to estimate the change of self-reported frequency of outdoor physical activity (PA) during cold and heat waves in a sub-tropical urban population and identify its predictors. Methods: A prospective population-based cohort telephone survey study was conducted in an Asian sub-tropical city, a week after a 2016 coldwave and followed-up 1.5 years after, a week after a 2017 heatwave. Measures on self-reported changes in outdoor PA in heat and cold waves, sociodemographic variables, health status, warning awareness, temperature-related attitudes and knowledge, and protective behaviours were collected. We conducted multivariable logistic regression analyses to assess predictors of change in outdoor PA over the two extreme temperature events. Results: Temperature and other meteorological variables were significantly different during the cold and heat waves from that prior. The response rate at follow-up was 42.8% (435/1017). Overall, more participants (53.3%) reported a decrease in PA in either or both the heat and cold waves, than reported an increase (10.3%), while 36.3% of participants maintained consistent PA in both the cold and heat waves. Decreased PA was associated with females, worsened health status in winter, awareness of temperature, and certain protective behaviours, while increased PA was associated with students, those under 45, higher income, and better health status in summer. Conclusions: Our findings suggest a greater decrease of outdoor PA during cold and heat waves, and identify gender, age, income, health status, temperature-related awareness, and protective behaviours to be associated.

### **001.03.24. Reduced Cognitive Function during a Heat Wave among Young Adults in Non-Air Conditioned Buildings**

Jose Guillermo Cedeno-Laurent

*Jose Guillermo Cedeno-Laurent<sup>1</sup>, Augusta Williams<sup>1</sup>, Youssef Oulhote<sup>1</sup>, Antonella Zanobetti<sup>1</sup>, Joseph G. Allen<sup>1</sup>, John Spengler<sup>1</sup>*

*1. Environmental Health, Harvard TH Chan School of Public Health, Boston, MA, United States.*

**Abstract:** In many areas of the world, buildings are designed for harnessing heat during cold winters, and thus can exacerbate extreme temperature exposures during heat waves (HWs) by maintaining elevated indoor temperatures even when ambient temperatures have subdued. Previous research has documented the impacts of ambient temperature on cognitive function, but few have observed the effects of extreme heat on indoor temperatures during daily routines. The objective was to evaluate the differential impact of HWs on cognitive function among university residents of air conditioned (AC) and non-AC dormitory buildings. Forty-four subjects (central air AC, n=24; non-AC, n=20) were followed before, during, and after a HW. STROOP and Addition/Subtraction (ADD) tests were administered daily for a period of twelve days. The causal effect of the HW on cognitive function was evaluated using difference-in-differences modelling. Difference-in-Differences estimates show an increase in reaction time (STROOP=13.4%, p<0.001; ADD=13.3%, p<0.001) and reduction in throughput (STROOP=-9.9%, p<0.001; ADD=-6.3%, p=0.08) during HW among non-AC residents relative to AC at baseline. These deficits were found in a young, healthy population of students, showing that the impact of HWs extend beyond vulnerable populations. Our findings highlight the importance of incorporating sustainable adaptation measures in buildings to preserve cognition, economic productivity, and health in light of a changing climate and heatwaves that will be more frequent, severe, and longer-lasting in the future.

## 001.03E. Environmental Exposures and Birth Outcomes

**Abstract:** Background: Several environmental contaminants have been identified as possibly influencing birth weight, mainly from single exposure studies. The Exposome paradigm offers perspectives to avoid selective reporting of findings and to control for confounding by co-exposures. Aim: To assess the association of the pregnancy exposome with birth weight. Methods: Within HELIX exposome project, 131 prenatal exposures, several of which had some a priori plausibility for an effect on fetal growth, were assessed using biomarkers and environmental models in 1,301 pregnant women from six European cohorts. Associations were assessed using deletion-substitution-addition (DSA) algorithm, which considers all exposures simultaneously, and exposome-wide association study (ExWAS), which considers them independently. We tested for pairwise interactions and corrected exposures for exposure misclassification through regression calibration. Results: Lead (median, 9.7 µg/l; interquartile range, IQR, 6.0 µg/l) was the only exposure associated with birth weight in the DSA model corrected for exposure misclassification (mean birth weight change for an IQR increase, -48 g, 95% confidence interval, -90; -6). No exposure passed the significance threshold of ExWAS corrected for multiple testing; the exposures most strongly associated with birth weight in ExWAS were lead (-48 g, 95% CI, -90; -6), fine particulate matter (PM<sub>2.5</sub>) absorbance in the third pregnancy trimester (-50 g; -94; -6) and PM<sub>2.5</sub> concentration in the third trimester (-33 g, 95% CI, -66, -1). There was no strong evidence of order-two interaction. Conclusions: Our study is one of the largest considering over 100 environmental exposures for effects on birth weight. Compared to single exposure studies, our Exposome approach allowed identifying exposures associated with birth weight while making all tests explicit, correcting for confounding by co-exposures, for exposure misclassification and considering interactions between exposures.

### **O01.03.26. Impact of Maternal and Paternal Preconception Urinary Bisphenol A (BPA) and Bisphenol S (BPS) Concentrations on Offspring Birth Size**

Carmen Messerlian

Abstract: Infant size at birth is considered an important marker of the intrauterine environment. Accumulating epidemiologic evidence has shown associations of prenatal exposure to BPA to reduced infant birth weight. However, effects of BPA exposure before conception in either parent is unknown. Epidemiologic evidence on BPS - a BPA substitute - is practically absent. We examined associations between maternal and paternal preconception, as well as maternal prenatal urinary BPA and BPS concentrations and size at birth among 346 singletons born to couples from the Environment and Reproductive Health (EARTH) Study, an ongoing prospective preconception cohort of women and men seeking fertility evaluation in Boston, Massachusetts. Infant birth weight and head circumference were abstracted from delivery records. Mean preconception exposures were estimated by averaging urinary ln-BPA and ln-BPS concentrations in multiple maternal and paternal urine samples collected before pregnancy, and prenatal exposures estimated via multiple maternal pregnancy samples collected per trimester. Associations of urinary BPA and BPS concentrations with birth weight and head circumference were estimated using multivariable linear regression. Maternal preconception urinary BPA concentrations were inversely associated with birth weight and head circumference in adjusted models: each ln-unit increase was associated with a decrease in birth weight of 119 grams (95%CI: -212, -27), and in head circumference of 0.60 centimeters (95%CI: -1.2, -0.03). Additional adjustment for gestational age or prenatal BPA exposure modestly attenuated results. Women with higher prenatal BPA concentrations had infants with lower mean birth weight (-75 grams, 95%CI: -153, 2). Paternal preconception urinary BPA concentrations were not associated with outcomes. No consistent patterns emerged for BPS exposure. This study suggests that the maternal preconception period may be a sensitive window for BPA effects on birth outcomes.

### **001.03.27. Associations between Prenatal Toxicant Exposures and DNA Methylation at Birth and in Adolescence**

**Abstract:** Epigenetic modification is one plausible mechanism linking early life environmental exposures to adverse health outcomes in childhood and adolescence. Evidence suggests bisphenol A (BPA) and phthalate exposures during sensitive periods modify the epigenome. We assessed whether in utero BPA and phthalate exposure are associated with DNA methylation levels throughout the genome at birth (n=89) and during early (n=79) and late adolescence (n=146) among children from the Early Life Exposures in Mexico to Environmental Toxicants (ELEMENT) study. We also assessed age-related change in DNA methylation among a subset of children (n=96) with samples at birth that could be matched with DNA from one or two adolescent time points. The exposures of interest were concentrations of nine phthalate metabolites and BPA, which were quantified in third trimester maternal urine samples. The outcomes were leukocyte DNA methylation, assessed via the Infinium MethylationEPIC BeadChip, in cord blood and blood collected during early and late adolescence. Differential methylation analysis by exposure was conducted for 786,024 CpG sites using an empirical Bayes method adjusting for sex and estimated blood cell type composition. A false discovery rate approach was used to adjust for multiple comparisons (q-values). Primarily hypomethylated CpG sites (q<0.05) by prenatal exposure to BPA and five phthalates (metabolites of DEHP, DiBP, and BzBP) were identified in cord blood. For example, higher third trimester BPA was associated with hypermethylation of one and hypomethylation of 33 CpG sites. The association persisted into late adolescence for two of the hypomethylated loci. In the longitudinal analysis, methylation at thousands of CpG sites differed between matched samples from birth and adolescence. Further analyses are underway to investigate evidence for environmental deflection, whereby prenatal exposure to toxicants alters the trajectory of age-related changes in DNA methylation.

### **O01.03.28. Relationship between Polybrominated Diphenyl Ether (PBDE) Levels in Maternal Serum and Fetal Tissues during Mid-Gestation of Pregnancy and Associations with Placental Biomarkers of Growth and Development**

Abstract: Polybrominated diphenyl ether (PBDE) compounds are flame retardant chemicals with adverse effects on brain development, which may be mediated by placental effects. Pharmacokinetic factors may lead to disproportionate exposure in the developing fetus, yet the maternal-fetal relationship is not well understood. We examined whether PBDE concentrations vary between mother and fetus during early-to-mid pregnancy and identified placental biomarkers of PBDE exposure that may influence placental growth and function using statistical methods that account for left censored PBDE data. We calculated correlations between levels of 19 PBDE congeners across three biological matrices (maternal serum, placenta tissue, and fetal liver) in 130 maternal-fetal units. We conducted an exploratory analysis in a subset of samples to identify biomarkers of PBDE exposures that may influence placental development and function. Detection frequency was highest for BDE-47 (> 93% across matrices). Congener BDE-28 was more highly detected in placental and fetal liver tissues than maternal serum (> 60% compared to < 20%). PBDE levels were similar or higher in maternal compared to placental and fetal tissues before and after lipid adjustment for most congeners. The median BDE-47 concentration in serum was 0.24 ng/g (95% CI: 0.22, 0.28), more than twice as high as the placental value of 0.10 ng/g (95% CI: 0.09, 0.12). The difference was more pronounced after lipid adjustment, with 35.5 ng/g lipid BDE-47 found in serum compared to 10.8 ng/g in the placenta. Lipid-adjusted BDE-28, -99, and -153 levels were ~ two times higher in the placenta and fetal liver. Biomarker changes were observed in a subset of 12 placental tissues. Prenatal PBDE exposures are correlated with maternal levels. Molecular biomarkers related to placental development and function may be informative measures of PBDE exposure in future studies.

### 001.03.29. Prenatal Exposure to Phthalates and Phenols and Infant Anogenital Distance

Abstract: Measurement of endocrine sensitive endpoints, especially those that are sexually dimorphic, such as anogenital distance (AGD), can be used as sentinels for later adverse health effects arising from prenatal exposure to endocrine disrupting chemicals. Some studies have reported reduced AGD in male infants with increasing maternal urinary phthalate concentrations; one study reported an association in female infants, while others report no significant associations. Human studies of phenols and AGD are sparse. Phthalate and phenol concentrations were measured in 1st trimester urines in the pan-Canadian MIREC Study. After birth, short and long measures of AGD were conducted in 197 male and 195 female infants. Multiple linear regression models were created to examine the relationship between the AGD and the exposure of interest, including specific gravity and significant confounders as identified from the change-in estimate procedure. The same confounders were kept for all phenol and phthalate models. The anus-clitoris distance was negatively associated with the phthalate metabolite MBzP ( $\beta = -1.24$ ; 95% CI -1.91, -0.57) and positively associated with MEP ( $\beta = 0.65$ ; 95% CI 0.12, 1.18). The anopenile distance was positively associated with MnBP ( $\beta = 1.17$ ; 95% CI 0.02, 2.32) and the molar sum of low molecular weight phthalates ( $\Sigma$ LMW) ( $\beta = 1.10$ ; 95% CI 0.13, 2.08). No significant associations were observed between prenatal BPA or triclosan urinary concentrations and AGD in either sex. Given the large number of associations examined, the statistical associations observed may have been due to Type 1 error. The inconsistency in results between studies of prenatal phthalate exposure suggests that this issue is yet to be resolved.

### **O01.03.30. Interdisciplinary Research in Assessing Relationships between Environmental Mixtures and Birth Outcomes: What Are the Essential Components for Collaboration?**

Osnat Wine

*Osnat Wine<sup>1</sup>, Jude Spiers<sup>2</sup>, Michael van Manen<sup>1</sup>, Katharina Kovacs Burns<sup>3</sup>, Alvaro Osornio Vargas<sup>1</sup>*

- 3. School of Public Health, University of Alberta, Edmonton, AB, Canada.*

**Abstract:** Despite the potential utility of interdisciplinary approaches in addressing complex environmental health research questions, there is paucity of research. The Data mining & Neonatal outcomes (DoMiNO) project is an interdisciplinary research which explored relationships between environmental mixtures and adverse birth outcomes using innovative data mining methods. The project applied a collaborative approach building on participation, expertise and perspectives of researchers, clinicians, and knowledge-users to gain new knowledge and facilitate knowledge translation. To better understand collaborative, interdisciplinary research, we used qualitative case study methodology to identify essential components that may support the interdisciplinary environmental research from the team's experience. Using the DoMiNO project as an exemplar case study of collaborative research, data were obtained from a focus group with ten DoMiNO team members. Applying thematic analysis we identified essential structures, mechanisms, and attributes that supported the interdisciplinary team including: keeping open channels for feedback and ongoing rapport; providing different opportunities for engagement, participation and learning; ensuring repetition of backgrounds, methods and processes in an inclusive and supportive environment. These components, built relationships, enabled learning and created bridges between team members and disciplines. Specific motivators for collaboration were identified: individual roles; sharing results; the need to be flexible, patient, open minded/'let go' of usual ways of thinking and leadership commitment to the team building process. Interdisciplinary research is a long and complex journey and could be challenged by its nature and context. The components described support the collaborative research process, resulting in a worthwhile experience which provided exciting results and knowledge translation and exchange activities with researchers and knowledge users.

*2. AMC, University of Amsterdam, Amsterdam, Netherlands.*

*3. ObjectTracker, Perchtoldsdorf, Austria.*

**Abstract:** Background: Exposure to light at night (LAN) can perturb the biological clock and affect sleep and health. Several epidemiological studies have evaluated LAN levels measured by satellites, but the validity of this measure as a proxy for personal LAN exposure is unclear. Also, outdoor light at night measured by satellites displays higher levels in urban environments, which means that this measure could potentially represent a proxy for other, likely urban, environmental exposures. Objectives: We evaluated correlations of satellite-assessed LAN with measured bedroom light levels, and explored correlations with other environmental exposures, in particular air pollution, green space and area-level socio-economic position. Methods: We compared satellite measurements with nighttime bedroom measurements in illuminance (Lux) in 251 children and additionally evaluated correlations to other urban exposures such as air pollution, area-level socio-economic position and surrounding green in 3021 children. Results: Satellite-measured LAN levels (nanoW/cm<sup>2</sup>/sr) were not correlated with bedroom-measured Lux (Spearman corr. coeff. -0.02). There was a weak correlation if parents reported influence of outdoor light on indoor light levels (rS=0.31). Satellite-measured LAN levels were correlated to air pollution (rS=0.76 with NO<sub>2</sub>, rS=0.71 with PM<sub>10</sub>) surrounding green (rS=-0.68 for green space within 1km of the home), and weakly to area-level socio-economic position (rS=0.24). Conclusions: Our study results indicate that outdoor satellite-assessed LAN levels are not a good proxy for nighttime personal exposure in bedrooms, but rather a proxy for other urban exposures. Studies planning to evaluate potential risks from LAN should therefore consider modifying factors such as curtains and indoor lighting and perform indoor or personal measurements to validate their exposure proxies. Other environmental exposures should be accounted for in epidemiological investigations.

## **001.03.32. How Green Is Green? Modeling Urban Greenness Exposure in Environmental Health Research**

Lorien Nesbitt

*Lorien Nesbitt<sup>1</sup>, Matteo Andreani<sup>1</sup>, Ingrid Jarvis<sup>2</sup>, Xiaojiang Li<sup>4</sup>, Carlo Ratti<sup>4</sup>, Ian Seiferling<sup>4</sup>, Paul Villeneuve<sup>3</sup>, Matilda van den Bosch<sup>1</sup>*

- 4. Massachusetts Institute of Technology, Cambridge, MA, United States.*

**Abstract:** Exposure to greenness has several health benefits, yet analyses are limited by uncertainty about accuracy of greenness metrics, often derived from different remotely-sensed data sources and using different spatial methods. This research (1) assesses the strengths and weaknesses of multiple greenness data sources and metrics for application in environmental health research, and (2) develops and tests an alternative greenness exposure metric that can be applied worldwide. **Methods:** We analyzed 5 data sources: Landsat time series, Landsat 8, Sentinel-2, RapidEye, and the Green View Index (GVI), derived from Google Street View. These data sets span various time series, resolutions and costs, and represent aerial and perspective views. We compared the Normalized Difference Vegetation Index (NDVI) using different imagery types and the GVI for various buffer distances around postal codes and examined sensitivity to spatial metrics and data sources. Based on these analyses, we constructed a spatially-weighted greenness metric combining data from Sentinel-2 and the GVI that incorporates neighbourhood street-level and at-home greenness. **Results:** NDVI showed correlations of between 0.65 and 0.85 among satellite types and demonstrated significant inter-variability. GVI showed low correlations with all other data types (0.25-0.40), suggesting an important new source of greenness data. Metrics were spatially sensitive, particularly at small distances and high resolutions, but lacked temporal sensitivity. Initial analyses suggest that the proposed metric is superior to traditional measures that overestimate neighbourhood greenness exposure and underestimate at-home exposure. **Conclusions:** This research is the first comparison of multiple remote sensing data sources and metrics, including both aerial and novel perspective views. It presents an alternative greenness exposure metric based on freely accessible data sources that may be applied in public health research internationally.

### **001.03.33. Associations of Surrounding Green, Air Pollution and Traffic Noise with General and Mental Health**

Jochem Klompmaker

*Jochem Klompmaker<sup>1</sup>, Gerard Hoek<sup>2</sup>, Lizan Bloemsmma<sup>1</sup>, Ulrike Gehring<sup>2</sup>, Alet Wijga<sup>1</sup>, Bert Brunekreef<sup>2</sup>, Erik Lebret<sup>1</sup>, Nicole A. Janssen<sup>1</sup>*

*1. National Institute for Public Health and the Environment, Bilthoven, Netherlands.*

*2. Utrecht University, Utrecht, Netherlands.*

**Abstract:** Background: Several studies showed indications that mental health is affected by environmental exposures. Objectives: To evaluate the effects of combined exposure to surrounding green, air pollution and traffic noise with general health and aspects of mental health. Methods: We linked a Dutch national health survey of 387,195 adults with an external database on prescription of anxiolytics (N05B), hypnotics and sedatives (N05C) and antidepressants (N06A). Moreover, we added data on surrounding green based on the Normalized Difference Vegetation Index (NDVI) or a land-use database (TOP10NL), annual average air pollutant concentrations (including particulate matter (PM<sub>10</sub>, PM<sub>2.5</sub>), and nitrogen dioxide (NO<sub>2</sub>) and road- and rail-traffic noise to the survey. We used logistic regression models to analyze associations of surrounding green, air pollution and noise exposure with self-reported general and mental health and medication prescription. Results: In single exposure models, exposure to air pollution was positively associated with all outcomes, while surrounding green was inversely associated with all outcomes. For example, for prescription of anxiolytics, we found an odds ratio [OR] of 0.83 (95% CI: 0.79, 0.88) per interquartile range [IQR] increase in green (TOP10NL) in a 1000m buffer and an OR of 1.14 (95% CI: 1.14, 1.19) per IQR increase in NO<sub>2</sub>. Road-traffic noise was only associated with prescription of anxiolytics (OR: 1.05 per 5 dB, 95% CI: 1.02, 1.07). Two-exposure analyses showed that the associations with surrounding green and air pollution generally remained, but they were attenuated. Conclusions: Surrounding green and air pollution were associated with general health and aspects of mental health.

### **O01.03.34. Green Space, Mental Health, Physical Activity and Body Mass Index in a Cohort of Women Up to 15 Years Postpartum: A Multilevel Longitudinal Study**

Xiaoqi Feng

*Xiaoqi Feng<sup>1</sup>, Thomas Astell-Burt<sup>1</sup>*

*1. Population Wellbeing and Environment Research Lab (PowerLab), University of Wollongong, Wollongong, NSW, Australia.*

**Abstract:** Background: Most epidemiological studies of green space and health use cross-sectional data, focus on green space quantity and pay little attention to sensitive periods in the lifecourse. Objective: To examine trajectories in mental health, moderate to vigorous physical activity lasting at least 30 minutes (MVPA) and body mass index (BMI) in association with measures of green space quantity and quality among women in the postpartum period. Methods: 3574 women who did not change neighbourhood were observed up to 6 occasions each over 12 years from 2004 onwards (20,084 observations). Multilevel growth curve models were used to examine the patterning of the Kessler 6 psychological distress scale, MVPA, and BMI. Green space quantity was measured by percentage land-use. Green space quality was self-reported. Models were adjusted for Indigenous status, qualifications, employment, area disadvantage and remoteness. Results: Green space quantity was associated with lower BMI (e.g. 21-40% coefficient: -0.73kg/m<sup>2</sup> (95%CI -1.39 to -0.08). This association between green space quantity and BMI strengthened as women aged. BMI was not associated with green space quality. However, women who lived near good quality green space reported better mental health consistently over time (rate ratio 0.89, 95%CI 0.85 to 0.93) and also participated in MVPA more often (rate ratio 1.04, 95%CI 1.01 to 1.07). A two-way interaction suggested quality green space supports the maintenance of MVPA over time. Conclusions: Green space quantity and quality matter for different health outcomes in the postpartum period. Quality green space may help prevent a decline in MVPA as women age.

**Abstract:** Background/Aim: A growing body of epidemiologic evidence has identified urban green space as a potential modifiable factor that can improve human health, especially mental health. However, little is known about whether urban green space exposure is associated with reduced risk of dementia. Methods: Our cohort consisted of ~1.7M adults aged 55 to 85 who were long-term Ontario residents prior to cohort inception in 2001. We restricted to individuals who resided in urban areas, and the cohort was followed until 2013. To quantify green space exposure, we used the Landsat 30m satellite-derived normalized difference vegetation index (NDVI) to represent the amount of green vegetation within 250m of individuals' homes using annual postal code addresses. Dementia incidence was ascertained using population-based health administrative data with a validated algorithm. Mixed effects Cox proportional hazards models were used to estimate the association between green space and dementia. The models included a variety of individual-level and area-level covariates (e.g., age, sex, SES, comorbidities, and air pollution). We also applied a number of sensitivity and stratified analyses to assess the robustness of our estimates. Results: Over the study period, 219,013 individuals in the cohort were diagnosed with dementia. The fully adjusted hazard ratio per IQR increase in green space was 0.96 (95% CI: 0.95-0.97). We did not observe any heterogeneity in our estimate after stratification by selected characteristics (estimates remained between 0.95-0.97). This estimate also remained consistent in sensitivity analyses of different NDVI buffer distances, SES adjustments, and model structures. Conclusions: Our study suggests that increased exposure to urban green space is associated with a reduced risk of dementia among older adults. To our knowledge, this is the first study to assess the relationship between urban green space and dementia.

### **O01.03.36. Active Commuting through Natural Environments and Mental Health: Results from the Phenotype Project**

Wilma Zijlema

*Wilma L. Zijlema<sup>1</sup>, Ione Avila-Palencia<sup>1</sup>, Margarita Triguero-Mas<sup>1</sup>, Christopher Gidlow<sup>2</sup>, Hanneke Kruize<sup>3</sup>, Sandra Andrusaityte<sup>4</sup>, Regina Grazuleviciene<sup>4</sup>, Mark Nieuwenhuijsen<sup>1</sup>*

- 3. National Institute for Public Health and the Environment (RIVM), Bilthoven, Netherlands.*
- 4. Vytautas Magnus University, Kaunas, Lithuania.*

**Abstract:** Background Urgent public health problems associated with the urban built environment include physical inactivity and mental health problems. Natural commuting routes that invite people to commute actively could be beneficial for an active lifestyle and mental health. This study focuses on the association between active commuting through natural environments and mental health. **Methods** This cross-sectional study was based on adult participants of the Positive Health Effects of the Natural Outdoor Environment in Typical Populations in Different Regions in Europe (PHENOTYPE) project. Data were collected in four European cities from Spain, the Netherlands, Lithuania and the United Kingdom. Data on commuting behavior and mental health (Medical Outcome Study Short Form (SF-36) mental health subscale) were collected with questionnaires. Adjusted associations were tested using multilevel analysis. **Results** Of n=3584 respondents, 27.3 percent walked or cycled to work or school in a normal week in the past months, and 42.9% commuted through natural environments on a daily basis. No association between active commuting and mental health was found. Adjusted analyses showed that respondents commuting through natural environments on a daily basis had on average a 2.75 (95% CI 1.67, 3.83) point higher score on the mental health scale than those not commuting through those spaces every day. In stratified analyses, this association was stronger among active commuters ( $\beta= 4.03$ , 95% CI 2.13, 5.94) compared to non-active commuters ( $\beta=2.23$ ; 95% CI 0.92, 3.53), but this interaction effect was not statistically significant ( $p=0.472$ ). **Conclusions** Commuting (active or non-active) through natural environments was related to better mental health, despite that active commuting was not related to mental health, and the amount of nature was not related to active commuting. Cities should invest in spatial planning policies targeted at natural commuting routes.

## O01.03G. Occupational Exposure and Worker Health

### **O01.03.37. Innovations in Applied Decision Theory for Occupational and Environmental Health and Safety**

Abstract: Miners are exposed to a complex mix of airborne hazards that can lead to chronic respiratory and cardiovascular diseases. Decisions about potential interventions to improve health and safety for miners require reasonable estimates of a potential intervention's impact. There are well-established methods for the analysis of epidemiologic data to estimate parameters that may be well-suited to etiological research and communication among academics, such as covariate-adjusted hazard ratios. In contrast, the epidemiological methods suited to decision-makers who evaluate policy choices is less well established. We have been developing innovative methods for decision making to improve mine health and safety, incorporating theoretical developments in decision theory and systems engineering. These users are likely to benefit from the proposed data visualization techniques that don't require epidemiological training to interpret. We illustrate some of these quantities and approaches in an applied context, and discuss how these can strengthen both epidemiology and decision making in occupational and environmental settings where people encounter a range of hazards. Results are illustrated using data for a recently-updated cohort of 28,546 Ontario uranium miners followed to ascertain vital status and cause of death through December 31, 2007. With 8572 deaths observed we rank-order cause-specific excess deaths, and years of life lost in a contemporary framework for competing events.

**Abstract:** Objectives: The primary objective of this study was to assess the relationship between heat exposure and occupational injuries in construction workers. Methods: The relationship between maximum daily humidex, a measure of apparent temperature, and Washington State Fund workers' compensation injuries in outdoor construction workers was assessed using a case-crossover design with time-stratified referent selection. Warm month (March-October) adult outdoor construction traumatic injury claims from 2000-2012 were spatiotemporally joined with high-resolution meteorological data. Conditional logistic regression with linear splines was used to assess the association between maximum daily humidex and injuries. Results: There were 63,720 traumatic injuries during the study period. The traumatic injury odds ratio (OR) was 1.0053 (95% CI 1.003, 1.007) per one °C change in humidex. In the splines analyses, we observed a nearly linear association between humidex and the risk of a traumatic injury. Stratified analyses suggested higher risk in younger (18-24 years) and older (over 54 years) workers, workers with lower extremity injuries, workers with less job experience, smaller employers, workers working in Western Washington, and time of injury before 12:30 pm. Conclusions: In this study of Washington outdoor construction workers, increasing maximum daily humidex was associated with increasing traumatic injury risk. Further work should explore mechanisms of the association between heat exposure and traumatic injuries. Injury prevention efforts in construction should address heat-related risk factors, particularly for high-risk workers. In addition, heat awareness campaigns should address outcomes beyond heat-related illness.

### **O01.03.39. Circadian Variation of Melatonin and Steroid Hormones and Metabolites in Male Shift Workers**

**Abstract:** Background: Night shift work has been associated with increased risk for breast and prostate cancer. The effect of circadian disruption on steroid hormone production and metabolism is a possible underlying mechanism that is under-investigated in humans. We assessed circadian rhythms of steroid hormones and melatonin in rotating male shift workers in within subjects comparisons minimising potential effects of confounding. Methods: We recruited 50 shift workers rotating in a 3week night, 3wk evening and 3wk morning schedule. Participants collected urine samples from all voids over 24 hours sampled on two working days (3wk night; 3wk morning shift). Urinary concentrations of 51 steroid hormones and metabolites (estrogens, progestagens, androgens, corticosteroids including cortisol) and 6-sulfatoxymelatonin (aMT6s), the main melatonin metabolite, were measured in all samples (creatinine corrected). Mean levels and peak time of hormones and metabolites were compared between night and day shifts using cosinor models. Results: Peak time of aMT6s production occurred 9 hours later in night compared with day shifts. Mean aMT6s levels were similar in night compared to day shifts indicating an adaptation of the rhythm to the shift schedule. Night shift work was associated with a phase delaying (later peak) effect for steroid hormones, which was strongest for cortisol, several androgens and progestagens. Workers in night shift had lower average levels of cortisol, cortisone and androgens but not for their metabolites, nor for progestagens and estrogens. Conclusions: Workers during night shift had a delay in peak time of aMT6s production compared to day shift. We found also mistimed production for several steroid hormones. The pattern observed indicates complex endocrine pathways to disease that involves a wide range of hormones and is not limited to changes in melatonin production and metabolism.

### **001.03.40. Occupational Noise, Job Strain and Salivary Cortisol: A Repeated-Measure Study**

*3. Department of Family Medicine, China Medical University Hospital, Taichung, Taiwan.*

**Abstract:** Background: Exposure to occupational noise and job strain have been reported to be associated with the salivary cortisol levels, but the combined effect is not clear. This study aimed to investigate individual and interactive associations between occupational noise exposure and job strain on salivary cortisol levels. Methods: We recruited 120 volunteers in an aircraft manufacturing company in Central Taiwan as study subjects. Each participant was performed 24-hour measurements of noise exposure and collected four salivary samples during different periods on the working day. The enzyme-link immunosorbent assay was applied to determine salivary cortisol levels. We also used questionnaire to obtain information related to job strain, sleep quality and other confounders. Multiple linear regression models were performed to analyze the association. Results: Workers exposed to  $\geq 75$  A-weighted decibels (dBA) had a significantly higher difference of salivary cortisol levels between 30-min waking-up and last-night sleep compared with that in workers exposed to  $< 75$  dBA and office workers, respectively. Workers exposed to high job strain (Index  $\geq 61$ ) had a significantly higher mean of salivary cortisol levels after 30-min waking-up and a significant difference between 30-min waking-up and last-night sleep than those with the low job strain (Index  $< 61$ ). Subjects co-exposed to noise levels  $\geq 75$  dBA and high job strain had a significantly higher mean of salivary cortisol levels after 30-min waking-up ( $0.371 \pm 0.098$  mg/dL,  $P < 0.001$ ) and a significant difference between 30-min waking-up and last-night sleep ( $0.323 \pm 0.094$  mg/dL,  $P < 0.001$ ) compared with those exposed to  $< 75$  dBA and low job strain. Conclusions: Occupational noise exposure and high job strain was associated with the increased salivary cortisol levels after 30-min waking-up. Co-exposure to noise and job strain may have a synergistic interaction with the salivary cortisol levels.

### **001.03.41. Hearing Loss in Agricultural Workers Exposed to Pesticides and Noise**

Nattagorn Choochouy

*Nattagorn Choochouy<sup>1</sup>, Pornpimol Kongtip<sup>1</sup>, Suttinun Chantanakul<sup>1</sup>, Noppanun Nankongnab<sup>1</sup>, Dusit Sujirarat<sup>2</sup>, Susan Woskie<sup>3</sup>*

Abstract: Pesticides have been identified as potential ototoxic agents, however it has been difficult to assess whether there is a synergistic relationship between pesticide exposure and noise since they frequently occur simultaneously in agricultural settings. This study was designed to investigate the risk of hearing loss in agricultural workers exposed to pesticides and/or noise. We recruited 317 Thai agricultural workers in three groups; 163 chemical-use farmers exposed to both pesticides and noise from agricultural machines (G1), 76 organic farmers exposed to only noise from machines (G2), and 78 organic farmers exposed to neither noise nor pesticides (G3). Questionnaires for pesticide use based in the NCI cumulative pesticide exposure algorithm (Dosemeci, 2002) and information on farm machinery use patterns along with noise levels measured on agricultural machinery were used to estimate cumulative exposure levels for noise and individual pesticides used by each person. All subjects underwent pure tone audiometric testing for low (L-PTA) and high frequencies (H-PTA). An average hearing threshold >25 dB was classified as hearing loss. A multivariate logistic regression analysis revealed that the G1 group (exposure to pesticide and noise) and the G2 group (noise only) had a significantly increased the risk of H-PTA hearing loss, compared with the G3 group (no noise or pesticide exposure) even after controlling for age, gender, smoking and years working as a farmer. Both higher cumulative noise exposures and higher cumulative organophosphate insecticides exposures were significantly associated with the increased odds of hearing loss in H-PTA, however, the interaction between noise and pesticides exposures was not significant. This study supports the hypothesis that exposure to organophosphate insecticides and noise increase the risk of hearing loss, but that this relationship is not synergistic.

**Abstract:** Introduction the biological mechanisms by which occupational exposures to irritants affect asthma are poorly understood. Oxidative/nitrosative stress pathway is involved in asthma and has been suggested as a mechanism of interest for the effect of irritants. Aim To test this hypothesis, we studied the associations between occupational exposures to irritants and 8 biomarkers related to oxidative/nitrosative stress. Analyses were done in participants without asthma, in order to evaluate associations independently of asthma-driven oxidative/nitrosative stress. Methods We analyzed data from 740 adults without asthma from the EGEA2 study, a case-control and family-based study (2003-2007; mean age: 47 years, 45% men). A new asthma specific job exposure matrix (Le Moual OEM 2018) was used to evaluate exposure to irritants including subgroups (e.g highly reactive chemicals, biocides; non-mutually exclusive categories). Exposure at the current job was evaluated in 3 levels (no exposure/medium/high). Biomarkers of internal dose, response or damage were measured in blood (SOD, GPX, catalase, FIOPs, NO<sub>2</sub>/NO<sub>3</sub>, CC16) or in exhaled breath (FeNO, 8-isoprostanes). Linear mixed models adjusted for age, sex and smoking were used to study the associations between exposures and biomarkers (outcomes), taking into account familial dependency. Results Overall, 31% of participants were exposed to irritants. Among the 8 biomarkers, only FIOPs level, a biomarker of damage related to oxidative stress, increased significantly across level of exposure to irritants (no/medium/high) (FIOPs GM[95%CI] 95[93-97], 98[95-102] and 99[94-104] RFU/mL, ptrend=0.04). Similar results were observed for highly reactive chemicals and biocides (all ptrend=0.002). All associations were stronger in men. Conclusion We observed a dose-response relationship between level of occupational exposures to irritants and FIOPs, supporting a role of damage due to oxidative stress in health effects of these exposures.

## 001.03H. Panel Studies of Air Pollution, Inflammation, COPD, and Lung Function

### **001.03.43. Association between Individual Indoor PM<sub>2.5</sub> Exposure and Peak Expiratory Flow Rate in Schoolchildren.**

Sanghyuk Bae

*Sanghyuk Bae<sup>1</sup>, Sungroul Kim<sup>2</sup>, Seongmin Jeong<sup>2</sup>, Ho-Jang Kwon<sup>1</sup>*

*2. Department of Environmental Health Science, Soon Chun Hyang University, Cheonan, Chungnam, Korea (the Republic of).*

**Abstract:** Background: PM<sub>2.5</sub> exposure is known to have adverse effect on respiratory function in children. However, most of the previous studies were based on the ecological evaluation of outdoor exposure. The aim of the present study is to examine the association between individually monitored indoor PM<sub>2.5</sub> concentration and peak expiratory flow rate (PEFR). Methods: We recruited 30 9-year-old children to conduct a panel study. Each child's PM<sub>2.5</sub> exposure was measured using indoor air quality station equipped with light-scattering particle sensor. The indoor air quality stations were installed at the children's classrooms and each child's bedroom at their homes. We calculated daily mean concentration for each child according to the time spent at each place. PEFR was measured using peak expiratory flow meter at their class rooms (during week days) and homes (during weekend) between 8 and 9 AM for 6 consecutive days. We measured the children's heights and weights to calculate the body mass index (BMI), and a questionnaire was administered to obtain information on covariates. We constructed mixed linear model to examine the association adjusting for age (months), sex, BMI, environmental tobacco smoke exposure and monthly average household income. Result: A total of 115 observations were included in the present analysis. The daily average PM<sub>2.5</sub> concentrations were between 38.6±11.6 and 67.3±15.8 µg/m<sup>3</sup>. The daily average PEFRs were between 266.1±48.57 and 276.2±48.86 L/min. The regression coefficient of PEFR (L/min) for the increment of 10 µg/m<sup>3</sup> of daily mean concentration of PM<sub>2.5</sub> was -2.27 (SE: 0.14, P-value: 0.098). Conclusion: We observed marginally significant adverse association between individually monitored PM<sub>2.5</sub> concentration and PEFR in 9-year-old children.

#### **001.03.44. Time-Lag Pattern of Short-Term Exposure to Traffic-Related Air Pollution and Changes in Exhaled Nitric Oxide in Asthmatic Children**

Nan Ji

*Nan Ji<sup>1</sup>, Pamela Ohman-Strickland<sup>3</sup>, Robert Laumbach<sup>2</sup>*

*2. Rutgers University Environmental and Occupational Health Sciences Institute (EOHSI), Piscataway, NJ, United States.*

*3. Rutgers University School of Public Health, Piscataway Township, NJ, United States.*

**Abstract:** Background/Aim: Short-term exposure to traffic-related air pollution (TRAP) has been associated with asthma exacerbation and increases in exhaled nitric oxide (FeNO), a biomarker of airway inflammation, with time lags ranging from several hours to a few days. Very few studies have examined TRAP-FeNO associations on less than 24-hour timescale. Moreover, most of the previous studies have used central-site exposure data. We aimed to investigate the lag structure of changes in FeNO in response to black carbon (BC), a marker for diesel exhaust particulate matter exposure, at hourly resolution measured by personal monitors from 35 asthmatic children in seaport-adjacent communities in New Jersey. Methods: Thirty five children with mild-to-moderate physician-diagnosed asthma wore micro-aethalometers (AE51, Aethlabs) for around 30 days (1071 observations in total). FeNO was measured daily in late afternoon using a NIOX MINO. Linear-mixed effect model was applied to quantify the BC-FeNO association after adjusting for day-of-week, temperature, age and gender. The lag was stratified as every two hours within 24-hour before the time of FeNO measurement. Results: Based on data from the first 9 subjects, FeNO level was positively associated with 24-hour average BC exposure (0.69% [95%CI: -1.62%, 3.05%] per one  $\mu\text{g}/\text{m}^3$  increase in BC) in the adjusted model. However, we observed inverse associations between BC and FeNO within 24 hour prior to FeNO measurement, and the association was strongest at lag 14-16 hours (-5.5% [95%CI: -9.38%, -1.44%] per one  $\mu\text{g}/\text{m}^3$  increase in BC) The strength of negative associations increased from lag 4-6 hours to lag 16-18 hours, and then decreased and becoming positive, over lags 18-20, 20-22 and 22-24 hours. Conclusions: Given the known high spatial and temporal variation in exposure to TRAP, the preliminary results support the need for further study of time-lag patterns between exposure to TRAP and acute asthma outcomes.

**Abstract:** The biological mechanisms involved in the associations between outdoor air pollution and asthma are poorly known. We studied the associations between long-term exposure to outdoor air pollution, plasma fluorescent oxidation products (FOPs), a global biomarker related to oxidative stress, and persistent asthma. The study was based on adults with current asthma followed in the Epidemiological Study on the Genetics and Environment of Asthma (EGEA), (EGEA2: 2003-2007, baseline; EGEA3: 2011-2013, follow-up). Air pollutant levels were estimated at the participants' residential address by ESCAPE (NO<sub>2</sub>, NO<sub>x</sub>, PM<sub>10</sub>, PM<sub>2.5</sub>) and the French institute of environment (O<sub>3</sub>). Persistent asthma was defined by current asthma (asthma symptoms, attack or treatment in the past 12 months) at EGEA2 and EGEA3. We conducted mixed models with random effects on city and familial dependence adjusted for age, sex and smoking habits. Among the 201 adults with current asthma at EGEA2 (39 years old in average, 48% men), 160 had persistent asthma at EGEA3. An increase of one interquartile range (IQR) of O<sub>3</sub> was associated with higher FOPs level (adjusted  $\beta$ : 0.02, 95%CI: 0.004-0.04), and with persistent asthma, although this later association was not statistically significant (adjusted (a)Odds Ratio: 1.34, 95%CI: 0.85-2.13). FOPs were not associated with the other air pollutants. Persistent asthma increased significantly with FOPs level (aOR: 1.81, 95%CI: 1.06-3.09 per an increase of 1 IQR of FOPs level). For the first time in adults, FOPs were associated with O<sub>3</sub> and persistent asthma. Our results add evidence on the role of oxidative stress as a biological mechanism involved in the effect of O<sub>3</sub> on the respiratory health.

**Abstract:** Introduction: Studies have shown effects of ambient particulate matter  $\leq 2.5$  microns in diameter (PM<sub>2.5</sub>) on oxidative stress biomarkers; however, less is known of these effects indoors in patients with chronic obstructive pulmonary disease (COPD). In this study, we assessed the association between indoor PM<sub>2.5</sub> apportioned into indoor and outdoor origin and biomarkers of oxidative stress. Methods: We recruited 82 men with COPD who ran a micro-environmental sampler in their home for 1 week up to 4 times a year (n=225 samples). Teflon filter samples were analyzed gravimetrically for indoor PM<sub>2.5</sub>, and outdoor PM<sub>2.5</sub> was measured at a central site. Daily indoor PM<sub>2.5</sub> was calculated and apportioned into indoor (PMin) and outdoor origin (PMout) using the indoor-outdoor sulfur ratio as a surrogate for infiltration. Urine samples were obtained for analysis of 8-OHdG and malondialdehyde (MDA). We fit mixed effects models with a random intercept for each participant and adjusted for age, race, season, time of urine collection, BMI, creatinine, diabetes, heart disease, indoor nitrogen dioxide, ambient temperature, and relative humidity. Results: We observed suggestive effects of total PM<sub>2.5</sub> on 8-OHdG, with the strongest effect on the 1 day lag (3.6% increase per IQR, 95% CI: -0.69-8.2). For MDA, there were statistically significant effects of total PM<sub>2.5</sub> with longer moving averages (strongest effect on the 1-7 day moving average: 6.5% per IQR, 95% CI: 0.88-12.4). Effects of PMout across time windows displayed similar yet stronger patterns compared to total PM<sub>2.5</sub>, with the greatest effects on the 1 day lag (16.7% per IQR, 95% CI: 1.8-33.7) for 8-OHdG and the 1-7 day moving average (19.3% per IQR, 95% CI: -0.9-43.6) for MDA. There were no statistically significant effects of PMin. Conclusions: Our results suggest that indoor infiltration of PM<sub>2.5</sub> of outdoor origin is positively associated with increased lipid peroxidation (MDA) and DNA oxidation (8-OHdG) in patients with COPD.

**Abstract:** Introduction Owing to rapid urbanization, residents in urban and rural greater Beijing area may be exposed to a diverse mixture and varying concentrations of ambient air pollution, resulting in different health responses. However, such comparative investigations are largely lacking.

**Methodology** This study is a part of AIRLESS project, a China-UK joint research which has integrated two intensive air pollution monitoring campaigns, and individual-based panel studies with 250 subjects (aged 40-70 years) recruited from two well established cohorts in urban and rural Beijing. This study aims to quantify and compare 1) ambient PM<sub>2.5</sub> concentrations in rural and urban Beijing, and 2) the acute effect of PM<sub>2.5</sub> exposure on respiratory and systemic inflammatory biomarkers in local residents. During winter 2016 and summer 2017, each subject completed 4 individual clinical measurements of exhaled NO (FeNO) and blood monocytes counts. These health outcome data were then linked with ambient PM<sub>2.5</sub> concentrations obtained from parallelly conducted local monitoring campaigns. Linear mixed-effect models were used to estimate any association. Results Preliminary results showed a clear spatial and seasonal variation of ambient PM<sub>2.5</sub> concentration, where daily mean(SD) of PM<sub>2.5</sub> during winter and summer were 85.5(78.7) and 48.7(19.2) µg/m<sup>3</sup> at the urban site, and 134.0(110.9) and 31.4(14.6) µg/m<sup>3</sup> at the rural site, respectively. An IQR increase in previous 1-day ambient PM<sub>2.5</sub> (58.0 µg/m<sup>3</sup>) was significantly associated with the elevation of FeNO [17.8%(95% confidence interval: 14.4-21.3%)] and monocyte counts [1.8%(1.5-2.1%)], after adjusting for covariates (P<0.05). Compared with urban subjects, rural residents showed a lower percentage change in FeNO (R vs. U = 13.1 vs. 30.1%) and higher in monocyte counts (R vs. U = 2.2 vs. 0.7%).

**Conclusions** Residents in urban and rural Beijing are exposed to different ambient PM<sub>2.5</sub> concentrations, and have different PM<sub>2.5</sub>-associated inflammatory responses.

### **001.03.48. Association between Air Pollution Exposure and Inflammation in Chronic Obstructive Pulmonary Disease Patients in Beijing, China**

Yuan Yao

*Xi Chen<sup>1</sup>, Yuan Yao<sup>1</sup>, Wu Chen<sup>1</sup>, Chengli Que<sup>2</sup>, Xiaoying Li<sup>1</sup>, Mei Zheng<sup>1</sup>, Lina Zhang<sup>3</sup>, Hanxiyue Zhang<sup>1</sup>, Xinghua Qiu<sup>1</sup>, Tong Zhu<sup>1</sup>*

**Abstract:** Background/Aim: Chronic obstructive pulmonary disease (COPD), characterized by chronic inflammation, is one of the leading causes of death worldwide. The biological mechanism of inflammation associated with exposure to air pollution in COPD patients are not well understood. To elucidate the association between air pollution exposure and inflammatory response in COPD patients, 135 subjects, including 53 stable COPD patients and 82 healthy controls, were recruited in a panel study in Beijing, China. Methods: Fractional exhaled nitric oxide (FeNO) and serum cytokines were repeatedly measured from each subject during 4 visits. Levels of air pollutants, including mass and number concentration of fine particulate matter, mass concentration of black carbon/organic carbon (OC)/elemental carbon/ heavy metals, gaseous pollutants, were online monitored. Linear mixed-effect models were used to estimate the different inflammatory responses to the air pollution exposure between COPD patients and healthy controls. Results: Exposures to SO<sub>2</sub>, OC and ultrafine particles (UFP) were positively associated with the levels of FeNO, which were more significant in COPD patients. Increases in levels of IL-6 associated with CO, Mn and Cu exposures in COPD patients were significantly higher than those in healthy controls. Exposures to UFP and Acc were associated with increasing levels of IL-15, which were more significant in COPD patients. Exposure to CO was associated with decreasing levels of IL-1 $\beta$ , IL-4, IL-10, IL-13 and IL-17A in healthy controls, which was not observed in COPD patients. Conclusions: In summary, COPD patients are susceptible to the acute respiratory inflammation associated with air pollution exposure, and their capabilities to regulate inflammation are weaker than healthy controls. Acknowledgement: The study was funded by National Program on Key Basic Research Project (2015CB553401). We thank all the volunteers, students and staff involved in COPD for their contributions.

O01.03I. Social, Economic, and Demographic Disparities in Air Pollution Exposure and Health Outcomes

**O01.03.49. A National County-Level Assessment of U.S. Nursing Facility Characteristics Associated with Long-Term Exposure to Traffic Pollution in Older Adults**

Yi Wang

*Yi Wang<sup>1</sup>, Hao Fan<sup>1</sup>, Aniruddha Banerjee<sup>1</sup>, Anne Weaver<sup>1</sup>, Michael Weiner<sup>1</sup>*

*1. Indiana University, Indianapolis, IN, United States.*

**Abstract:** Background: Long-term exposure to ambient air pollution increases disease risk in older adults. Nursing facilities located near major roadways potentially expose older adults to traffic pollution. No studies, however, have described the association between nursing facilities and traffic pollution. Methods: We obtained data on facility- and census-tract-level characteristics of 15,706 U.S. facilities from the Medicare Nursing Home Compare datasets. We calculated distance to major roadways and traffic density for each facility. Results: In the contiguous U.S. (as of 2014), 345,792 older adults, about 27% of residents in non-hospital facilities, lived within 150 m major roadways (A1 or A2) in 3876 (28% of sampled) facilities. Nationally, for-profit facilities, high-occupancy facilities, and facilities in census tracts with higher percentages of minorities were more likely to have higher exposure to traffic. Counties in Virginia, New York City, and Rhode Island have the highest percent of residents and facilities near major roads. Conclusion: Nationally, over one-quarter of sampled facilities are located near major roadways. Attributes potentially associated with higher exposure to traffic included "for-profit" and "higher minority census tract". Proximity to major roadways may be an important factor to consider in siting nursing facilities. Our results inform potential intervention strategy at both county and facility level.

## **O01.03.50. Associations between Long-Term PM2.5 Exposure and Cardiovascular Outcomes Are Modified by Neighborhood Socioeconomic Effects in an Urban Area of North Carolina**

Abstract: Exposure to PM2.5 air pollution, as well as neighborhood socioeconomic status (SES), are associated with cardiovascular disease (CVD) and diabetes. The joint effect of SES and PM2.5 on these outcomes can aid in understanding the effects of total environment on health. In this study, we examined whether neighborhood SES modified the effects of long-term PM2.5 exposure on the following outcomes: coronary artery disease index >23 (CAD) at the time of the index visit as determined by coronary catheterization, hypertension, and diabetes. We defined 6 neighborhood SES clusters based on a prior analysis of Ward's Hierarchical clustering of 11 Census variables. We analyzed data from 2192 cardiac catheterization patients residing in Wake, Durham, or Orange County, North Carolina. For each patient, we estimated annual mean PM2.5 concentration using a hybrid model with a 1x1 km resolution. All outcomes were assessed from medical records. We used logistic regression models adjusted for age, sex, race, body mass index, and smoking status, to assess cluster-specific and overall associations between PM2.5 and outcomes. We used interaction terms to define interactions by SES clusters. We observed significantly greater associations between PM2.5 and hypertension in clusters 1 (OR 1.22, 95% CI 0.99-1.50, pint 0.03) and 2 (OR 1.64, 95% CI 1.16-2.32, pint 0.003) compared to referent cluster 3 (OR 0.93, 95% CI 0.82-1.07). Clusters 1 and 2 were urban and had relatively high proportions of black populations, impoverished, non-managerial occupations, unemployed, and single-parent homes. In contrast, Cluster 3, the referent cluster, was urban with high proportions Bachelor's degree, and low proportions impoverished, non-managerial occupations and unemployed. In conclusion, neighborhoods of relative disadvantage have a stronger association between PM2.5 and hypertension compared with neighborhoods of relative SES advantage. This abstract does not necessarily reflect EPA policies.

**Abstract:** Background. Immigrants make up 20 percent of the Canadian population, yet recent immigrants (< 20 years in Canada) are often excluded from air pollution mortality analyses to reduce possible confounding. Thus, little is known about the mortality impacts of fine particulate air pollution (PM<sub>2.5</sub>) on this population and how it changes over time. Methods. We used the 2001 Canadian Census Health and Environment Cohort (CanCHEC), a longitudinal cohort of 3.5 million subjects of which 764,000 were immigrants linked to annual mobility and PM<sub>2.5</sub> concentration from 1994 to 2011. Exposures were assigned as a 3 and 8-year mean prior to the follow-up year. Income tax files were used to account for residential mobility among respondents using postal codes, with probabilistic imputation used for missing postal codes in the tax data. We used Cox survival models to determine hazard ratios (HRs) for cause-specific mortality, and assessed year of immigration and country of origin. Results. In partially adjusted models (individual socioeconomic variables, airshed, and population centre size) stratified by age and sex, preliminary analyses of only immigrants compared the full cohort with immigrants as a covariate showed slightly lower HR estimates for cardiovascular (CVD) mortality: HR=1.07 (95% CI: 1.03 to 1.12) vs. HR=1.08 (95% CI: 1.06 to 1.10); and ischemic heart disease (IHD) mortality: (HR=1.09; 95% CI: 1.02 to 1.15) vs. (HR=1.11; 95% CI: 1.08 to 1.14) per 5 µg/m<sup>3</sup> increase in PM<sub>2.5</sub> concentration respectively. The HR estimates of CVD, IHD and other chronic diseases increased with increased time in Canada among immigrants. Interaction models with country of origin and sensitivity analyses are on-going. Conclusions. Preliminary analyses suggest that air pollution is an equal opportunity risk factor; however, the relationship between immigration, health and air pollution is complex, partly due to unknown previous exposures along with a diverse and dynamic country of origin population.

## **001.03.52. PM2.5 and Mortality: Modification of the Association by Personal and Area Level Indicators of Socioeconomic Status**

Maayan Yitshak-Sade

**Abstract:** Background Individual and contextual sociodemographic characteristics are important determinants of health. We investigated the modification of the relationship between PM2.5 (particulate matter <2.5 microns) exposure and all-cause natural mortality risk, by individual sociodemographic characteristics, neighborhood census sociodemographic indicators and measures of racial and economic segregation. Methods We obtained geocoded 2001-2011 mortality records from the Massachusetts Department of Public Health (n=527,208), and matched them to highly spatially and temporally resolved PM2.5 predictions from satellite-based models. We examined the association between PM2.5 and natural mortality using case-crossover analysis. We defined three groups of potential modifiers: (1) individual characteristics, (2) neighborhood sociodemographic characteristics from the US Census, and (3) neighborhood measures of racial and economic segregation and dissimilarity which incorporate the individual race and the uniformity of races and economic groups within the neighborhood. Results Each 10µg/m<sup>3</sup> increase in two-day average exposure to PM2.5 was associated with a 1.32% [0.94%; 1.69%] increase in mortality risk. The risk was higher among decedents without a college education and older persons (>85). The risk was modified by economic segregation and dissimilarity among younger aged decedents (<65) and effects were stronger in neighborhoods with higher percentiles of racial dissimilarity among ages ≥85 (5.93% increase, [3.03%;8.91%]). Census sociodemographic indicators did not modify the association in either of the age groups. Conclusion PM2.5 exposure is associated with increased daily deaths, and individual characteristics and sociodemographic indicators modify those risks. Neighborhood measures of segregation and dissimilarity, which incorporate individual and contextual sociodemographic characteristics, were found to be stronger modifiers than neighborhood census sociodemographic indicators.

### **001.03.53. Effect Modification of the PM2.5 Association with Birthweight by Local Residential Racial and Economic Segregation**

Kelvin Fong

*Kelvin C. Fong<sup>1</sup>, Kevin J. Lane<sup>2</sup>, Maayan Yitshak-Sade<sup>1</sup>, Itai Kloog<sup>3</sup>, Jaime E. Hart<sup>4</sup>, M. Patricia Fabian<sup>2</sup>, Antonella Zanobetti<sup>1</sup>, Joel D. Schwartz<sup>1</sup>, Francine Laden<sup>1</sup>*

**Abstract:** Background: Maternal exposure to particulate matter under 2.5  $\mu\text{m}$  in aerodynamic diameter (PM<sub>2.5</sub>) during pregnancy is a well-established risk factor for decreased birthweight. Recently, there has been increased interest in how neighborhood racial and economic segregation modify health impacts of PM<sub>2.5</sub>. We therefore investigated the association between PM<sub>2.5</sub> and birthweight at different levels of racial and economic segregation. Methods: For each birth in Massachusetts from 2001 to 2013, we calculated the average PM<sub>2.5</sub> maternal exposure during pregnancy using the geocoded maternal residence at birth, infant birthdate, and clinical gestational age. Racial residential segregation (RRS) and economic residential segregation (ERS) indices were calculated at Census block group level and matched to maternal residence. RRS and ERS range from -1 to 1, with -1 indicating geographic concentration of the least privileged and 1 the most privileged. We quantified the association between PM<sub>2.5</sub> and continuous birthweight overall and in each quartile of RRS and ERS with regression analysis, controlling for individual risk factors. Results: In 783,966 singleton full-term live births, an interquartile range (IQR) increase in PM<sub>2.5</sub> (2.3  $\mu\text{g}/\text{m}^3$ ) was associated with a 20 g (95% CI: 18, 23) decrease in birthweight. RRS and ERS individually modified this association. The estimated birthweight decrease per IQR increase in PM<sub>2.5</sub> was 6 g (95% CI: 0, 12) in the lowest quartile of RRS (1Q); 22 g (95% CI: 17, 28) in 2Q; 17 g (95% CI: 12, 22) in 3Q; and 5 g (95% CI: 0, 9) in 4Q. For ascending quartiles of ERS, the estimated decreases per IQR increase in PM<sub>2.5</sub> were 12 g (95% CI: 7, 18), 24 g (95% CI: 19, 29), 14 g (95% CI: 9, 19), and 15 g (95% CI: 10, 20) respectively. Conclusions: Neighborhood racial and economic segregation modified the association between PM<sub>2.5</sub> and decreased birthweight. The impacts of PM<sub>2.5</sub> were most severe among those who lived in neighborhoods in the middle quartiles of RRS and ERS.

### **O01.03.54. Source-Specific Contributions to Fine Particulate Matter Exposure Disparities in the United States**

Abstract: Efficiently addressing environmental injustice in air pollution exposure requires knowledge of the predominant sources of air pollution exposure disparities. Previous studies that have linked emissions sources to environmental injustice have used proximity to the emissions source as an exposure metric, but locations of emissions sources and the spatial patterns of the resulting concentrations are often only weakly correlated. We use the year-2014 US EPA National Emissions Inventory (NEI) and the Intervention Model for Air Pollution (InMAP) to estimate fine particulate matter (PM<sub>2.5</sub>) concentrations resulting from the more than 5,000 emissions source types included in the inventory, and we quantify associated exposure disparities by race-ethnicity. Preliminary results suggest 54% of source types, representing 62% of total PM<sub>2.5</sub> exposure, result in higher average exposures for minorities as compared to whites. Overall, minorities are exposed to average concentrations 1.7  $\mu\text{g m}^{-3}$  higher than whites. Significant source groups—those that contribute at least 1% of overall exposure—disproportionately impacting minorities include residential natural gas burning, commercial cooking, and highway vehicles (average exposure for minorities is 90%, 73%, and 39% higher, respectively, than whites). Significant source groups disproportionately impacting whites include coal power generation and agriculture (average exposure for whites is 26% and 15% higher, respectively, than minorities). These results can help policy-makers direct targeted efforts to mitigate inequitable exposure to air pollution.

- 2. Columbia University, Palisades, NY, United States.*

Abstract: Journals, time activity diaries, and other manual annotations of a participant's activities can be labor intensive, particularly if a wide variety of activities are required to meet study goals. To make better use of sensor data collected from the RTI MicroPEM, we developed a machine learning model to distinguish between "biking" and "non-biking" activity from MicroPEM accelerometer data. We started with a data set of 3424 observations for a single individual performing a set of activities (biking while standing, walking on treadmill, etc.) in a gym. These activities were timed and annotated by a researcher in an accompanying activity journal. MicroPEM accelerometer data sampled at 1 Hz to capture the 3-axis acceleration forces. Though more detailed activities were annotated for quality control, only two activity classes were assessed for the pilot, comprising of a 53/47 split between "biking" and "not-biking" observations. We used "N-fold" and "LOSO" cross validation methods to develop the activity identification algorithm. We obtained 94% accuracy with the Gradient Boosted Trees machine learning classification model. The accuracy increased to 99% after applying a sliding window that incorporated the statistical distribution of the data within +/- 3 minutes of the data under evaluation. Initial application of this algorithm to daily activities collected from study participants that commute via bicycle in New York City yielded a similar accuracy of 98%. Accuracy was assessed by correlating the time periods identified as biking with the GPS data recorded with the Strava application. The misclassification of 2% of the "biking" times most frequently occurred at the start and end of a biking session when the participant mounted or dismounted their bicycle. The ability to identify bicycling from the MicroPEM accelerometer data will provide a means to directly link the PM nephelometer data to this activity. Future work will apply machine learning to other activities.

### **001.03.56. Crashes when It Splashes: Link between Precipitation Type and Fatal Accidents in the United States**

Shubhayu Saha

*Shubhayu Saha*<sup>1</sup>

*1. Centers for Disease Control and Prevention, Atlanta, GA, United States.*

**Abstract:** Introduction: We conduct a comprehensive national assessment of the risk of fatal traffic crashes by examining the association of precipitation intensity with fatal accidents, specifically investigating how this association changes across seasons and time of day, controlling for known risk factors like alcohol and drug use. Methods: We combine two nationally representative datasets from 2006-2011 for the United States. First dataset contains the time and precise location of every reported fatal crash in the US from the National Highway Traffic Safety Administration (NHTSA). Second dataset contain estimates of actual precipitation conditions at the time of the fatal crash for the entire contiguous US using the high-quality national-scale NOAA NEXRAD reanalysis data at 1-km resolution with a 5-minute rate. The high temporal and spatial resolution of these datasets allow precise linkages of crashes with environmental conditions at the time of the crash. We estimate the fractional attributable risk of these crashes from the prevailing intensity of precipitation. Results: There were 184,169 reported fatalities in the NHTSA database for 2006-2011. Among those accidents involving alcohol and/or drugs, precipitation produces no discernible impact on the likelihood of a fatal accident. Meanwhile, about one quarter of the risk of fatal accidents without alcohol and/or drugs that take place during precipitation can be attributed to the precipitation itself. The attributable risk is least during light precipitation (FAR = 0.23) and greatest during moderate and heavy precipitation (FAR = 0.43 and 0.59, respectively). The risk is highest during the daylight hours. On an annual scale, light precipitation adds far more risk during the winter months than during summer, while heavier precipitation contributes a more seasonally independent risk. Conclusion: Our results show that precipitation at all intensities contributes a significant risk to fatal traffic accidents.

### **001.03.57. Using Spatially Resolved Pollution Data to Plan Bicycle Infrastructure**

Darby Jack

*Darby Jack<sup>1</sup>, Nicholas Pantaleo<sup>2</sup>, Cara Smith<sup>1</sup>, Qiang Yang<sup>3</sup>, Jonathan Thornburg<sup>4</sup>, Patrick Kinney<sup>5</sup>, Steven Chillrud<sup>3</sup>*

Abstract: Highly resolved pollution data offers novel insights into where and when urban residents incur air pollution exposures. Armed with such data, urban planners can design infrastructure to minimize exposure. New York City, which has over 450,000 bike trips/day, offers a compelling place to examine the relationship between cycling infrastructure and exposure. Drawing on a novel high resolution dataset collected by volunteer bicycle commuters in New York City (n=43 with each participant riding as many as 12 times), we quantify how proximity to truck routes and type of bicycle infrastructure drive air pollution exposure during bike commutes. About 40% of the total cycling routes in NYC are along or within 50 meters of a designated truck route, and approximately 55% of the total distance traversed by study participants was within 50m of a truck route. We found that proximity to truck routes affects exposure, with decreasing concentrations with distance. For example, a simple dichotomy of data shows that while mean BC of < 50m of truck routes = 4.30 ug/m<sup>3</sup>, mean BC of > 50m of truck routes = 3.10 ug/m<sup>3</sup> (p = 0.015), with larger differences observed for different distance cut-offs. Bicycle lanes in New York City are categorized based on the degree of separation from vehicular traffic. Incorporating truck route and bike lane class data made available by the New York City Department of Transportation (DOT) with annual average daily traffic from the state DOT as a measure of traffic density, we model exposure to BC on a minute-by-minute basis as a function of bike lane class. Based on these results, we assess the potential health benefits that could be obtained by redesigning cycling infrastructure to minimize air pollution exposures.

### **O01.03.58. Spatial Variation of Injury Risk in a Metropolitan Area, According to Home Location, Transportation Mode, Distance Travelled and Route**

Felix Lamothe

*Jillian Strauss<sup>2</sup>, Patrick Morency<sup>1</sup>, Felix Lamothe<sup>1</sup>, François Tessier<sup>1</sup>, Sophie Goudreau<sup>1</sup>, Celine Plante<sup>1</sup>, Michel Fournier<sup>1</sup>, Pierre-Léo Bourbonnais<sup>2</sup>, Jean-Simon Bourdeau<sup>2</sup>, Catherine Morency<sup>2</sup>*

- 2. École Polytechnique de Montreal, Montreal, QC, Canada.*

Abstract: At the route level, traffic volume and road geometry greatly influence the risk of injury. At the state or country level, population rates of road injuries vary according to household density and transportation mode. This study aims to integrate these two perspectives to describe the spatial variation of injury risk according to home location within a metropolitan area. Police reports (2006-2010) provided injury data (e.g. crash location). Population trips, travel mode and routes were estimated using a representative Origin-Destination Survey (2008) for the entire Montreal Metropolitan area. Home location for each individual was classified into population density quintiles, using property assessment rolls. Regression models were developed to estimate the number of car occupant, bus occupant and pedestrian injuries, accounting for exposure to traffic as well as road geometry. These models were applied to predict the risk associated with each road, intersection and highway and then accumulated throughout each trip. Results show that in the densest sector, injuries per kilometre of road are six times greater compared to the least dense one. At intersections, road segments and on highways, the number of injuries is strongly associated with traffic volume and proxies of vehicle speed. Unsurprisingly, trips by public transit are safer than by car. At the individual level, the likelihood of injury increases with distance traveled. People living in the least dense sector make more trips by car and travel greater distances and are almost three times more likely to be injured than those in the densest sector. Within a metropolitan area, more injuries occur in the densest sector, however it is the population living in the least dense sector that have the greatest risk of injury. In urban settings, road injury prevention strategies should not only target road geometry but also urban development.

### **O01.03.59. Impacts of Multi-Modal Commuting on Personal Air and Noise Exposures and Airway Inflammation**

Yisi Liu

*Yisi Liu<sup>1</sup>, Bowen Lan<sup>1</sup>, Jeff Shirai<sup>1</sup>, Elena Austin<sup>1</sup>, Changhong Yang<sup>2</sup>, Edmund Seto<sup>1</sup>*

*1. Department of Environmental and Occupational Health Science, University of Washington, Seattle, WA, United States.*

*2. Sichuan CDC, Chengdu, Sichuan, China.*

**Abstract:** Background: Modern mobility can include mixtures of transportation options, which potentially impact pollution exposures and health. Objectives: To investigate variations in traffic-related air and noise pollution exposures and cardiorespiratory effects in different microenvironments in Chengdu, China. Methods: Three sections of a city were chosen as locations for a scripted exposure study: The urban core, a developing neighborhood, and a suburb. Exposures for four commuting modes (car, bus, subway, and shared bike) with overlapping routes were measured using portable instruments (measuring PM<sub>2.5</sub>, Black Carbon, and noise) in summer and winter (5 repeats in each season). We assessed the feasibility of collecting health measures (ECG, breathing rate, respiratory minute ventilation, fractional exhaled nitric oxide, and spirometry measurements) in winter for four healthy, non-smoking young adults. Health measures on commute days were compared to a control measurement collected two days after the last commute. Results: Air pollutant measures showed large seasonal variance, with winter medians more than three times higher than those in summer (PM<sub>2.5</sub>: 33 vs 123 ug/m<sup>3</sup>, BC: 2395 vs 9125 ng/m<sup>3</sup>). The highest PM<sub>2.5</sub> and BC levels were measured in the urban core (both p<0.0001). Noise tended to be higher in the summer, and was higher in the suburb than other neighborhoods (p<0.0001). In summer, riding the subway had the highest pollution levels, while riding a car was found to be the least polluted mode (p<0.0001). In winter, the highest air pollution levels were found for shared bike use (p<0.0001); subway and bus trips had the lowest PM<sub>2.5</sub> and BC level respectively (p<0.0001). Preliminary linear mixed modeling suggested that riding a car may be associated with increased airway inflammation (p=0.004). Conclusion: Results from this study suggest that mode, location and season of transportation impact personal traffic-related pollution exposure and airway inflammation.

### **001.03.60. Associations between Children's Physical Activity and Exposures to Air Temperature and Green Space in Mexico City**

Sandy Wong

*Sandy Wong<sup>1</sup>, Martha M. Téllez-Rojo<sup>2</sup>, Alejandra Cantoral<sup>2</sup>, Eunice Moncada<sup>2</sup>, Ivan Pantic<sup>2</sup>, Emily Oken<sup>3</sup>, Jennifer W. Thompson<sup>3</sup>, Katherine Svensson<sup>1</sup>, Robert Wright<sup>1</sup>, Andrea Baccarelli<sup>4</sup>, Itai Kloog<sup>5</sup>, Allan Just<sup>1</sup>*

- 5. Ben-Gurion University of the Negev, Beersheba, Israel.*

**Abstract:** Background/Aim: Global increases in sedentary behavior are a major public health concern requiring research into its causes. We investigate environmental factors such as temperature and green space that may predict physical activity among children 4-6 years of age, since active children are more likely to exercise regularly over the course of their life. Methods: We use children's data collected in the years 2013-15 in a subset of the Mexico City PROGRESS cohort (n=383). Children wore accelerometers for a week recording their activity levels. For physical activity, we calculated mean, maximum, and minimum hourly vertical counts by day and by week. We estimated children's exposure to green space using 50m resolution seasonal maximum NDVI (Normalized Difference Vegetation Index), a satellite-based measure of greenness; and exposure to air temperature with a daily 1km resolution model developed by our group using data from satellite-based land surface temperature and weather stations (CV R<sup>2</sup>=0.89). For our analysis, we use multiple linear regression models adjusted for child and mother covariates, including child BMI z-scores. Results: We find maximum daily temperature to be positively associated with maximum hourly vertical counts. Children had on average 0.06 SD units higher exercise for each 1°C higher ambient temperature (p=0.002, temperature range 11-31°C). When stratified by gender, the significant and positive association holds for girls but not for boys. We do not find a significant relationship between green space and physical activity. Discussion: Our findings suggest that temperature, but not green space, is an important environmental influence associated with children's physical activity, particularly for early school age girls in Mexico City. Our findings may not generalize to other climates or non-urban areas that have more green space. We recommend that future epidemiological projects consider weather variations when analyzing physical activity data.

O01.03K. Stress, Inflammation, and Cardiopulmonary Outcomes in Scripted and Experimental Air Pollution Exposure Studies

**O01.03.61. Forced Expiratory Volume in 1 Second Is Not Affected by Exposure to Diesel Exhaust and Cycling Exercise in Individuals with Exercise-Induced Bronchoconstriction**

Sarah Koch

*Sarah Koch<sup>1</sup>, Christopher Carlsten<sup>2</sup>, Jordan Guenette<sup>3</sup>, Michael Koehle<sup>1</sup>*

*1. School of Kinesiology, University of British Columbia, Vancouver, BC, Canada.*

*2. Faculty of Medicine, University of British Columbia, Vancouver, BC, Canada.*

*3. Centre for Heart Lung Innovation, University of British Columbia, Vancouver, BC, Canada.*

**Abstract:** **PURPOSE:** To assess the effect of diesel exhaust (DE) exposure before and during cycling exercise in individuals with exercise-induced bronchoconstriction (EIB) on lung function following the inhalation of a bronchodilating agent (salbutamol, SAL). **METHODS:** Seventeen 22-34 year-olds (9 females) with an EIB diagnosis were included in this double-blind randomized crossover study. In four exposure visits, participants performed a 30-minute cycling bout while breathing either DE or filtered air (FA) after the inhalation of either 400 $\mu$ g of SAL or placebo (PLA). After the inhalation of SAL or PLA, participants sat in the exposure chamber for 60 minutes. Following this rest period, participants cycled for 30 minutes at 50% of peak work rate achieved on their screening visit. During both the rest and cycling bouts, participants breathed either DE (PM<sub>2.5</sub> = 300 $\mu$ g/m<sup>3</sup>) or FA. Forced expiratory volume in 1 second (FEV<sub>1</sub>) was assessed at baseline, after the 60-minute resting period, immediately upon completion of the cycle bout, and 60 minutes after the completion of the exercise bout (~3 hours after IBA treatment). Participants were asked to withhold asthma medication 12 hours prior to testing. **RESULTS:** The inhalation of SAL led to a significant increase in FEV<sub>1</sub> in the DE (baseline: 3.5 $\pm$ 0.9L; 60 minutes following rest: 3.8 $\pm$ 1.0L, p=0.04) and FA condition (baseline: 3.5 $\pm$ 0.9L; 60min: following rest: 3.8 $\pm$ 0.9L, p=0.02). Breathing DE at rest and during the cycle bout did not lead to changes in FEV<sub>1</sub> (p= 0.67). After the inhalation of PLA, FEV<sub>1</sub> averaged consistently at 3.5-3.6L ( $\pm$ 0.9L) in the DE and FA conditions across all four measurement points (p > 0.05). The cycle exercise did not affect FEV<sub>1</sub>, meaning that participants neither experienced exercise-induced bronchoconstriction nor bronchodilation. **CONCLUSIONS:** The exposure to DE prior to and during a 30-minute cycle bout does not affect FEV<sub>1</sub> in individuals with EIB following the inhalation of a bronchodilating agent.

## **O01.03.62. Particulate Metal Exposures Induce Plasma Metabolome Changes in a Commuter Panel Study**

**Abstract:** Identifying air pollution (AP) components driving human health response remains costly and complex, with inconsistencies among results across studies. Sensitive, high-throughput methods may aid in discovery of AP-mediated health effects. Using measurements collected as part of a large, panel-based study of car commuters, we examined in-vehicle AP, targeted inflammatory biomarkers, and metabolomic profiles to trace metabolic perturbations associated with on-road, AP exposures through systems-level approaches. **Methods:** A 60-person panel of adults participated in a scripted crossover study, where each person conducted a highway commute and either a side-street commute or clinic exposure. Pre- and post-exposure dried blood spots were taken to examine 2h changes in targeted inflammatory biomarkers (interleukins and acute phase proteins) and plasma for 10h changes in the metabolome. High resolution metabolomics was compared with both exposures and changes in biomarkers. Features associated with either in-vehicle exposures or inflammatory biomarkers were subjected to pathway analysis using mummichog and MetaCore. **Results:** Particulate metal exposures and changes in inflammatory biomarkers were associated with measurable changes in the plasma metabolome. 150 total metabolite features associated with either aluminum, iron, or lead exposures. Of these, 9 overlapped with features associated with changes in one of IL-8, IL-1 $\beta$ , IL-6, or hs-CRP. Notably, metabolic pathway analysis of significant features indicated that these traffic-related pollutants were associated with leukotriene and arachidonic acid biosynthesis and tryptophan metabolism. **Conclusions:** In-vehicle metal exposures associated with within-day perturbations of several pathways; however, one pathway, leukotriene metabolism, was also associated to changes in inflammatory cytokines. Systems-level approaches generated actionable hypotheses with greater confidence through the use of multiple analytical platforms.

### **001.03.63. Exposure to Black Carbon and Acute Subclinical Health Effects: Results from a Panel Study in Three European Cities**

5. Colorado State University, Fort Collins, CO, United States.

Abstract: Short-term exposure to high levels of traffic-related air pollution has been linked to numerous adverse health effects. Often exposure peaks are encountered in urban environments near traffic where individuals are also physically active. We aimed to assess the short-term effects of air pollution, physical activity, and their interaction on a set of subclinical cardiovascular and respiratory outcomes in healthy adults. A panel of 122 adults was recruited in 3 European cities: Antwerp, Barcelona, and London. Participants completed three measurement weeks in which they pursued their daily routines, and measured their personal exposure to black carbon (BC) (microAeth AE51) and physical activity level (SenseWear armband). After each week, health markers were measured: heart rate variability, retinal vessel diameters, lung function (FVC, FEV1, PEF), and fractional exhaled nitric oxide (FeNO). We used mixed effects regression models to assess responses to physical activity, BC, and their interaction. Separate models were used for 2-hour and 24-hour time windows before the health assessment. Physical activity and BC had opposite, independent effects on lung function in the 2-hour time window (physical activity on FEV1: +14.63mL,  $p < 0.1$ ; BC on PEF: -102.19mL,  $p < 0.05$ ). We observed an interaction effect between physical activity and BC on FEV1 and FVC ( $p < 0.05$ ), which suggests a protective effect of physical activity offsetting the BC effects on lung function. We also observed an increased sympathetic tone with both physical activity (log LF/HF: +0.08;  $p < 0.01$ ) and BC (log HF: -0.14 ms<sup>2</sup>;  $p < 0.1$ ). We did not observe consistent responses in FeNO or retinal vessel diameter in the 2-hour time window. No statistically significant changes were observed in the 24-hour time window. Independent effects from physical activity and BC exposure were observed; a combined effect was found for FEV1 and FVC indicating a protective effect of physical activity to BC exposure in the 2-hour time window.

### **O01.03.64. Modification of Ozone-Induced Changes in Lung Function by Moderate Recent Life Stress**

Radhika Dhingra

*Radhika Dhingra<sup>1</sup>, Juliette Kahle<sup>1</sup>, Martin Case<sup>1</sup>, David Diaz-Sanchez<sup>1</sup>*

*1. Clinical Research Branch, Environmental Protection Agency, Chapel Hill, NC, United States.*

Abstract: While changes in lung function (LF) due to ozone (OZ) exposure are well-documented in healthy populations, potential sources of response heterogeneity, like stress, remain uncharacterized. Though examined in diseased populations, the modifying effect of stress on air pollution induced LF changes has not been characterized in a healthy population. To assess the impact of stress on OZ-induced LF changes, we conducted a case-crossover study, where healthy subjects (N=40; 18-33y) were exposed in a controlled chamber to clean air (CA) and 300 ppb OZ for 2 hrs, with a  $\geq 2$ -week wash out between exposures. LF outcomes, FEV1, FVC, FEF25-75, were measured pre-exposure, post-exposure, and 18 hrs after exposure (follow-up). Recent stress levels were assessed using the Perceived Stress Scale-10 (PSS.10) survey, and dichotomized into low (PSS.10 < 10), and moderate/high (PSS.10  $\geq 10$ ; hereafter, high) stress. We used a linear mixed effects model with random participant intercepts to estimate and qualitatively compare these four contrasts: high vs. low stress, under CA and OZ exposures; OZ vs. CA, among the high and low stress groups. Findings are reported as difference in % change from pre-exposure baseline. High and low stress groups did not discernibly differ under CA exposure. In all participants, post-exposure FEV1, FVC and FEF25-75 were diminished with OZ exposure as compared to CA, but the decline in the high stress group (e.g. FEV1: -9.96, 95%CI(-6.66, -13.3)) was larger than in the low stress group (e.g. FEV1: -6.76 (-3.77, -9.75)). At follow-up, the effect of OZ on LF outcomes was indistinguishable from CA in the low stress group, but remained diminished in the high stress group. Our findings suggest that return to baseline of OZ-induced LF decline is attenuated in individuals experiencing moderate/high stress, and that stress may be responsible for a portion of heterogeneity in LF that is observed in response to OZ. This abstract does not necessarily represent EPA policy.

### **O01.03.65. Exposure to Air Pollution - A Novel Staircase-Function Response Mechanism of Stress Restoration**

Miaomiao Liu

*Miaomiao Liu<sup>1</sup>, Xingyu Liu<sup>1</sup>, Jianxun Yang<sup>1</sup>, Jun Bi<sup>1</sup>*

*1. State Key Laboratory of Pollution Control and Resource Reuse, School of the Environment, Nanjing University, Nanjing, China.*

**Abstract:** Introduction: Given the epidemiological facts that exposure to air pollution induce the stress, reasonable hypothesis is made that it also hampers the stress restoration and further cause the mental health concerns. However, no studies examined the specific mechanisms so far. Methods: We adopted an environmental physio-psychological experiment paradigm of stress recovery to investigate the question. The experiment had three steps: (1) After entering the lab and sit in front of a computer monitor, participants were asked to relax for 1 minute. (2) Participants then took 10-minutes oral English tasks in the form of TOEFL test for evoking the stress. (3) Immediately after the stress evocation, 110 participants were randomly divided into seven groups. Then they were asked to relax for 3 minutes in the front of the monitor that displayed one group of blank pictures and six target groups of air pollution pictures with PM2.5 concentrations ranging from 11, 32, 51, 108, 165, to 231  $\mu\text{g}/\text{m}^3$ , respectively. During the experiment, Galvanic Skin Reaction (GSR) were selected as stress indicators and acquired using a BIOPAC MP 150 System and aggregated for obtaining the mean and maximum of GSR for each 10-seconds interval using Acqknowledge 4.0. Results and Discussion: According to the stress recovery patterns, six target groups were regrouped into three categories that matched the Air Quality Grading system in China well. For the first one with PM2.5 of 11-32  $\mu\text{g}/\text{m}^3$  (Grade: Good), participants presented the most obvious stress reductions of around 20% by the end of the third minutes. For the second one with PM2.5 of 51-108  $\mu\text{g}/\text{m}^3$  (Grade: Fine and Mild Pollution), moderate stress reductions of less than 10% were observed. For the third one (Grade: Moderate and Severe Pollution), participants' stress levels have not been reduced, but increased since the second minute. It revealed that there was a novel staircase-function response mechanism of stress restoration to air pollution exposure.

## **O01.03.66. A Crossover Study of In-Vehicle Air Filtration and Acute Changes in Heart Rate Variability and Cognition among Healthy Adults**

Robin Shutt

*Gary Mallach<sup>1</sup>, Robin Shutt<sup>1</sup>, Errol Thomson<sup>1</sup>, David van Rijswijk<sup>1</sup>, Frédéric Valcin<sup>1</sup>, Ryan Kulka<sup>1</sup>, Scott Weichenthal<sup>1</sup>*

*1. Health Canada, Ottawa, ON, Canada.*

**Abstract:** Background: Traffic-related air pollutants (TRAP) are known to negatively affect cardiovascular health, and personal exposures may be highest during rush hour commutes. We examined the effectiveness of cabin air filtration at reducing in-vehicle exposures to TRAP, and whether these exposures were associated with short term changes in heart rate variability (HRV) and cognition in healthy adults. Methods: A crossover study of cabin air filtration and in-cabin exposure to TRAP was conducted in Montreal, Canada in 2014. Forty-eight participants were exposed to TRAP during two separate commutes of approximately 90 minutes: one trip with an electrostatic cabin air filter and one trip without a cabin air filter. In-vehicle and outdoor rooftop measures of ultrafine particles (UFPs), fine particle matter (PM<sub>2.5</sub>), black carbon (BC), nitrogen dioxide (NO<sub>2</sub>), and volatile organic compounds (VOCs) were collected during the commute. HRV parameters were measured before, during, and after each exposure period. Linear mixed effects models were used to examine relationships between in-cabin air pollution concentrations and changes in time and frequency domain measures of HRV. Results: The cabin air filter reduced in-vehicle UFP concentrations by 28%, (mean difference= 26,232/cm<sup>3</sup>, 95% CI: 11,733-40,730), PM<sub>2.5</sub> by 30% (mean difference= 6 ug/m<sup>3</sup> 95% CI: 5-8), and BC by 32% (mean difference= 1,348 ng/m<sup>3</sup> 95% CI: -1,654-1,042 ng/m<sup>3</sup>). The air filter did not reduce in-vehicle concentrations of NO<sub>2</sub> or VOCs. In general, cabin air filtration was not consistently associated with changes in HRV. PM<sub>2.5</sub>, UFPs and BC were positively associated with changes in both time and frequency-domain measures of HRV during and after the commute; these associations tended to be stronger among women. Conclusions: Electrostatic cabin air filters can lower in-vehicle exposures to TRAP, particularly those pollutants produced in high concentrations by diesel vehicle traffic, and may modify acute cardiac effects of TRAP.

## S01.03A. Effects of Prenatal Exposure to Environmental Neurotoxicants on Health and Neurodevelopment

**Abstract: Background/Aim:** Developmental neurotoxicity is a global health concern. Neurotoxicants easily cross the placenta and fetal blood brain barrier, and their constant presence in maternal blood ensures that the fetus is exposed during critical periods of brain development. Exposure to neurotoxicants has been shown to be associated with children's neurobehavioural outcomes, which in turn has economic, social and health consequences. The aim of this presentation is to describe two large longitudinal pregnancy cohorts investigating associations between prenatal and childhood exposures to neurotoxicants and children's neurodevelopmental outcomes in a high (Canada) and a low income country (Tanzania). **Method and Results:** The Alberta Pregnancy Outcomes and Nutrition (APrON) cohort (2189 mothers) was recruited in Alberta, Canada. Data on prenatal exposure to endocrine disruptors (i.e., BPA, BPS, phthalates), heavy metals (i.e., methyl mercury, lead, arsenic, manganese) and perfluorooctane sulfonate (PFOS) during the second trimester of pregnancy has been collected for 563 children. In addition, we have collected biosamples at 3-4 years of age to assess childhood exposure levels. Children's neurodevelopment and behaviour at 2, 3-4 and 5-6 years is being assessed across multiple domains using standardized measures. The Mining and Health cohort (N = 1056) was recruited in Geita and Magu Districts, Tanzania where artisanal and small scale gold mining is a significant industry. In this cohort, data is being collected on prenatal exposure to mercury, arsenic and other heavy metals, pregnancy and birth outcomes, and early childhood health and development. **Conclusions:** These two pregnancy cohorts, one from a high income country and the other from a low income country, are providing much needed data on known and emerging neurotoxicants and their long term effects on children's health, neurodevelopment and behaviour.

**Abstract:** Background/Aim: Prospective birth cohort studies are powerful means of investigating associations between environmental chemical mixtures and neurodevelopmental outcomes in children, but there are few developmental toxicity studies in animal models with environmentally relevant chemical mixtures. We investigated the neurodevelopmental toxicity of methylmercury (MeHg), in the presence of an organic contaminant, perfluorooctane sulfonate (PFOS). These chemicals are two of the most ubiquitous contaminants in dietary fish, but little information is available on their toxicological interaction in neurodevelopmental models. Method: Pregnant Sprague-Dawley rats were exposed daily to PFOS (1mg/kg), MeHg (1mg/kg), Low PFOS+MeHg (0.1mg/kg, 1 mg/kg, respectively) or PFOS+MeHg (1 mg/kg, each) from gestation day 1 to weaning. Newborns were monitored for physical milestones and changes in innate behaviour. Juveniles underwent tests of spontaneous activity, anxiety, memory and cognition, and brain metabolomics (lipids, biogenic amines, amino acids). Results: Newborns from combined exposure groups had delayed responses and decreased weight gain. In contrast, juveniles showed evidence of chemical antagonism when individual exposure was compared to co-exposure. PFOS alone induced hyperactivity in the open-field and increased performance on the rotating rod but these effects were absent in the combined exposure groups. This antagonism was also noted in metabolomic analyses of rat cortex. Individual chemical exposures altered metabolomic profiles in a manner consistent with behavioural tests and specific changes in neurotransmitter (i.e. GABA) concentrations may account for the observed changes. Conclusions: Results demonstrate that neurodevelopmental effects from a simple binary mixture may vary with the developmental window examined, and that mixture effects are not necessarily predictable based on exposures to individual test substances.

### **S01.03.03. Prenatal Bisphenol A Exposure and Brain Structure in Preschool-Aged Children**

Melody Grohs

*Melody Grohs<sup>1</sup>, Jessica E. Reynolds<sup>2</sup>, Tyler Pollack<sup>2</sup>, Jiaying Liu<sup>3</sup>, Jonathan W. Martin<sup>3</sup>, Catherine Lebel<sup>2</sup>, Deborah Dewey<sup>4</sup>, The APrON Study Team<sup>5</sup>*

**Abstract: Background/Aim:** In Canada, over 90% of the population has detectable levels of bisphenol A (BPA) due to dietary and non-dietary exposure. Human epidemiological studies have demonstrated behavioral effects of BPA exposure in children. Further, reported effects have been found to be sex-specific. Although behavioral outcomes have been examined, there is limited understanding of the effects of BPA exposure on children's brain structure. This study examined the effects of maternal BPA exposure on subsequent child white matter brain structure at 3 to 6 years of age. **Method:** Maternal total BPA concentrations in spot urine samples obtained during the second trimester of pregnancy were analyzed for 99 women. Their children participated in magnetic resonance imaging (MRI) between 3 to 6 years of age. Associations between prenatal BPA exposure and child fractional anisotropy and mean diffusivity within 10 isolated white matter tracts were investigated, controlling for sex and total maternal creatinine levels. Anisotropy and diffusivity provide measures of white matter structure and maturity. **Results:** Significant positive associations were observed between the level of prenatal BPA exposure and child white matter mean diffusivity within the splenium, and the right inferior frontal occipital, inferior longitudinal fasciculus, uncinate fasciculi, and pyramidal fibers. Significant sex differences were found, with more associations noted among females. No associations were observed between prenatal BPA exposure and child white matter anisotropy. **Conclusions:** Higher prenatal BPA exposure was related to higher mean diffusivity in white matter tracts at 3 to 6 years of age. Developmental studies show that with age, white matter anisotropy increases and diffusivity decreases in typically developing children. The current findings suggest that exposure to higher levels of BPA prenatally may be related to reduced white matter maturity in preschool aged children.

#### **S01.03.04. Prenatal Exposure to Bisphenol A and Bisphenol S and Neurodevelopment in Children at 2 Years of Age**

Jiaying Liu

**Abstract:** Background/Aim: Bisphenol A (BPA) is an endocrine disruptor that is ubiquitous worldwide. Evidence suggests that it is a neurodevelopmental toxicant with sex-specific effects. Bisphenol S (BPS), an alternative to BPA, has been found to influence neurodevelopment in animal studies; however, human studies of BPS are limited. This study investigated the associations between prenatal exposure to BPA and BPS and child behaviour and neurodevelopment at 2 years of age, adjusting for maternal nutrient status, and co-exposure of heavy metals. The effect of child sex was also examined. Method: Total BPA and BPS concentrations were analyzed in spot urine samples from pregnant women in their second trimesters. Maternal neurotoxic metals and nutrient status/intake were evaluated using blood samples or dietary data collected during pregnancy. At age 2 years, children's neurodevelopment was assessed by the Bayley Scales of Infant and Toddler Development-Third Edition (Bayley-III; n=394) and behaviour was evaluated using the Child Behaviour Checklist (CBCL; n=358). Linear regression models were used to examine the associations between prenatal bisphenol exposure and Bayley-III scores and negative binomial regression was used for CBCL scores. Results: After adjusting for covariates, increasing BPA exposure was associated with poorer Social Emotional scores on the Bayley-III in boys ( $\beta=-5.1$ ; 95% CI: -9.6, -0.63) and higher scores on the attention problem subscale of the CBCL in all children ( $\beta=0.22$ ; 95% CI: 0.01, 0.43). Higher BPS exposure was associated with lower Motor scores on the Bayley-III for girls ( $\beta=-4.9$ ; 95% CI: -9.6, -0.20) and higher scores on the anxious/depressed subscale of the CBCL in all children ( $\beta=0.28$ ; 95% CI: 0.01, 0.54). Conclusions: Higher prenatal exposure to BPA and BPS was associated with poorer child development and more behavioural problems at age 2, with sex-specific effects on development.

### **S01.03.05. Environmental Contaminant Exposure during Pregnancy and Executive Function in 2 Year-Old Children**

Kayla Ten Eycke

*Kayla Ten Eycke<sup>1</sup>, Jiaying Liu<sup>2</sup>, Jonathan W. Martin<sup>2</sup>, Gerald Giesbrecht<sup>3</sup>, Deborah Dewey<sup>3</sup>, The APrON Study Team<sup>4</sup>*

*1. Department of Paediatrics, University of Calgary, Calgary, AB, Canada.*

*2. Department of Laboratory Medicine and Pathology, University of Alberta, Edmonton, AB, Canada.*

*3. Departments of Paediatrics and Community Health Sciences, University of Calgary, Calgary, AB, Canada.*

*4. University of Calgary and University of Alberta, Calgary and Edmonton, AB, Canada.*

**Abstract:** Background/Aim: Bisphenol A (BPA) is an ubiquitous environmental chemical and research suggests it has neurotoxicant effects on neurodevelopment, including on executive functions (EF). Bisphenol S (BPS) is often used as a replacement for BPA, but may not be a safer alternative. This study examined associations among human prenatal exposure to BPA, BPS, and 5 common toxic heavy metals, and EF in children at 2 years of age. Method: Maternal urinary BPA and BPS, and blood heavy metals (i.e., cadmium, mercury, lead, arsenic, antimony) were measured during the second trimester of pregnancy in 352 women in the Alberta Pregnancy Outcomes and Nutrition (APrON) study. Children's EF at 2 years was assessed with the Behavior Rating Inventory of Executive Function-Preschool (BRIEF-P). Multiple regression models were run with time of urine collection, gestational age at urine collection, child sex, and household income as covariates. Results: Higher prenatal BPA, uncorrected for urinary creatinine, was associated with poorer BRIEF-P Shifting ( $\beta = .919$ ,  $t(351) = 2.149$ ,  $p = .032$ ) and Global Executive Composite scores ( $\beta = .976$ ,  $t(351) = 2.015$ ,  $p = .045$ ). Higher prenatal BPS, uncorrected for urinary creatinine, was associated with significantly higher Flexibility scores ( $\beta = -1.036$ ,  $t(351) = -2.151$ ,  $p = .032$ ). Effect sizes in creatinine corrected models were slightly smaller. Heavy metal exposures did not predict EF above and beyond the effects of BPA or BPS. Conclusions: These findings suggest that higher levels of prenatal BPA exposure are associated with poorer EF outcomes in children at 2 year of age. Higher prenatal exposure to BPS and other heavy metal contaminants were not associated with poorer EF outcomes in young children. Our results support the importance of examining the differential effects of prenatal exposures to various contaminants on neurocognitive outcomes in young children.

### **S01.03.06. Prenatal Exposure to Phthalates and Cognitive Outcomes in Early Childhood in the Apron Cohort**

**Abstract: Background/Aim:** Phthalates are ubiquitous endocrine disrupting chemicals. Previous research suggests an association between prenatal maternal phthalate levels and adverse behavioural outcomes in children. However, no studies have investigated the association between prenatal phthalate exposure levels and cognitive outcomes in children 3 to 4 years of age. **Methods:** Twelve urinary phthalate metabolites were measured in urine collected in the second trimester from 416 women enrolled in the Alberta Pregnancy Outcomes and Nutrition (APrON) Study. Cognitive outcomes (IQ) of the children of these women were assessed at 3 to 4 years of age using the Wechsler Preschool and Primary Scale of Intelligence - Fourth Edition (WPPSI-IV). Associations between prenatal phthalate concentrations and children's cognitive outcomes were estimated using linear regression models. **Results:** Of the twelve urinary phthalate metabolites measured, eight metabolites showed statistically significant findings. After adjusting for gestational age, birth weight, maternal ethnicity, and maternal education, higher concentrations of both low molecular weight phthalate metabolites (miBP and mMP) and high molecular weight phthalate metabolites (mEHHP and mEHP) were associated with lower Full Scale IQ. Analyses of the WPPSI-IV subscales revealed that higher concentrations of the mBzP, mCOP, mECP, and mNP metabolites were associated with lower scores on Working Memory, Fluid Reasoning, Visual Spatial and Verbal Comprehension subscales of the WPPSI-IV. **Conclusions:** Higher prenatal maternal urinary metabolite concentrations of both low and high molecular weight phthalates were associated with poorer cognitive outcomes in children at 3 to 4 years of age. As phthalate exposures are widespread in the Canadian environment, these findings are of public health significance.

### **S01.03.07. Exposure to Arsenic and Mercury in Pregnant Women in Gold Mining Areas in Tanzania**

**Abstract: Background/Aim:** In Tanzania, artisanal and small scale gold mining (ASGM) operations expose entire communities to mercury and arsenic via the water they drink, the food they eat, the soil in which their food is grown, and the air they breathe. Prenatal exposure to mercury and arsenic is associated with reproductive risk factors including still birth, low birth weight, and congenital anomalies, and with poorer developmental outcomes in children. The Mining and Health study is investigating differences in prenatal exposure levels between women who live in ASGM areas and those who do not, and associated reproductive risk and early developmental outcomes of their children. **Method:** 1056 pregnant women were recruited during antenatal care clinic visits. For total mercury, a drop of whole blood was collected on filter paper (Whatman #903) following a simple finger prick to obtain a dried blood spot (DBS). For total arsenic, unprovoked morning urine samples were collected. DBS and urine samples were analyzed using inductively coupled plasma mass spectrometry. **Results:** Preliminary findings revealed that pregnant women with a history of living in an area with ASGM activities had blood mercury levels that were at least twice as high (95% CI: 0.54-2.4;  $p < 0.0001$ ) as women who had no history of living in ASGM areas. Living in an area with ASGM activities was associated with an increase in urine arsenic level of 54% (95% CI: 1.32-1.8;  $p < 0.0001$ ) compared to those not living in those areas. **Conclusions:** Living in ASGM communities was associated with higher blood total mercury and total arsenic levels in pregnant women. These higher blood levels could be associated with increased reproductive risk in the women and poorer neurodevelopmental outcomes in the children, which is the ongoing focus of this study.

## S01.03B. Food, Nutrition and Environmental Health among First Nations in Canada

### **S01.03.08. Critical Considerations in Environment and Health for First Nations**

Tonio Sadik

*Tonio Sadik<sup>1</sup>*

*1. Assembly of First Nations, Ottawa, ON, Canada.*

Abstract: The intersection of environment and health represents a unique set of considerations with respect to First Nations, many of which are informed by a deep attachment to land, language and culture. In the case of First Nations, the environment is generally not an external reality, but one inextricably tied to history, ceremony, subsistence and place. Environmental pollution places at risk not only First Nations' health - a critical aspect in its own right - but when a community can't fish or gather medicinal plants, for example, the impacts permeate well beyond health, potentially disrupting a complex tapestry that is best characterized by Indigenous Knowledge Systems (IKS). Where non-Indigenous peoples can elect to source alternate foods, or even relocate, First Nations are defined by their specific territories that are, in turn, reflected in their very identities. To buy fish or to move away disrupts the reciprocal relationships that many First Nations have with their particular environments - these are not interchangeable. As a result, adverse health outcomes arising from pollution are only one facet of the many unique challenges that may be faced by First Nations in Canada when environmental contaminants jeopardize food gathering and harvesting practices. This context will be explored at the outset of this session as a basis for a more meaningful appreciation of the topics thereafter.

### **S01.03.09. Food, Nutrition and Food Security in First Nations Communities**

Malek Batal

*Malek Batal<sup>1</sup>*

*1. Nutrition, Université de Montreal, Montreal, QC, Canada.*

Abstract: In the general Canadian population, household food insecurity is estimated at 9% and often cited as too high for a high-income country. In parallel, the First Nations Food, Nutrition and Environment Study (FNFNES), a 10-year study, investigated food security levels in 6487 households on 93 reserves across Canada south of the 60th parallel using the same tool in national Canadian surveys, the Household Food Security Survey Module (HFSSM) and found very high rates of food insecurity, ranging from a low of 29% in reserves in Ontario and a high of 47% in reserves in Alberta. These unacceptably high levels are associated with high levels of obesity (BMI  $\geq 30$ ) among adults (42%-52%) and equally high rates of self-reported diabetes (17-26%). Moreover, diets in all surveyed regions did not meet, on average, Health Canada's recommendations. In many First Nations communities, traditional food (TF), that is food harvested from the local environment, continues to hold a special cultural and spiritual importance, even if its consumption is low, relatively to food items purchased from the store. This low consumption can be explained by the many barriers reported by the survey participants (climate change, cost of equipment, lack of time, economic activities such as mining and agriculture, etc.). In addition, most participants reported desiring more TF in their diet, indicating another form of food insecurity associated with lack of access to TF. On the other hand, and despite the nutrition transition away from a traditional food system towards a diet dominated by store-bought foods, TF continues to contribute significantly to intakes of macronutrients and several micronutrients of concern in this population, highlighting its great nutritional importance. Preserving the quality of TF and ensuring access are of paramount importance if solutions to the worrying rates in food insecurity and chronic disease are to be found.

### **S01.03.10. The Legacy of Mercury Exposure in Grassy Narrows First Nation**

Donna Mergler

*Donna Mergler<sup>1</sup>, Judy Da Silva<sup>2</sup>*

*1. Biological Sciences, Université du Québec à Montreal, Montreal, QC, Canada.*

*2. Grassy Narrows First Nation, Grassy Narrows, ON, Canada.*

Abstract: In 1960 and '70s, a plant in Northern Ontario dumped 10,000 tons of mercury (Hg) into the Wabigoon-English river system, which was used by the people of Asubpeeschoseewagong Netum Anishinabek (ANA, Grassy Narrows First Nation) for their livelihood (fishing guides, fisheries) and their main source of food. A large number of community members became ill; many with Minamata Disease. When fishing was stopped, they lost their jobs and a highly nutritious dietary mainstay. Hg in fish decreased over time until the mid-80's, but remains high. Concerned about the possible effects of historic and present Hg on their health and wellbeing, ANA undertook a Community Health Assessment (CHA), with the support of several federal and provincial ministries. The CHA survey questionnaire was based on the First Nations Regional Health Survey (2008/2010), with added questions on childhood and current fish consumption (indicators of Hg exposure) and health outcomes, known to be associated with Hg exposure. This allowed us to (i) compare the ANA responses to other First Nation communities on health, education, individual and community wellness, socio-economic status, food security and access to health care; (ii) examine the influence of past and present fish consumption on these outcomes. ANA community members organized the fieldwork; web-based surveys were filled out for 800 adults and children. Descriptive statistics were used to compare prevalence between ANA and other First Nation communities, and multivariate analyses were applied to examine the associations between fish consumption practices and the various outcomes. The study adopted the principles of Ownership, Control, Access and Possession (OCAP) of knowledge and information by the First Nation. In keeping with OCAP principles, the results of the study are presently (March - May) being shared and discussed in the community. In this communication, we will present the process and the major findings.

### **S01.03.11. Research and Monitoring Efforts on First Nations Environmental Health Issues**

Constantine Tikhonov

*Harold Schwartz<sup>1</sup>, Constantine Tikhonov<sup>1</sup>*

*1. First Nations and Inuit Health Branch, Department of Indigenous Services, Government of Canada, Ottawa, ON, Canada.*

Abstract: The First Nations and Inuit Health Branch, Health Canada/Indigenous Services Canada has been working on several large programs to assist First Nations in understanding and reducing the impact of exposure to chemical hazards in their environment: The First Nations Environmental Contaminants Program (FNECP); the First Nations Food, Nutrition and Environment Study (FNFNES) and the First Nations Biomonitoring Initiative. Initially, the Mercury Biomonitoring Program, which ran from 1970 to 2000, monitored exposure to mercury by collecting over 70,000 blood and hair samples in over 500 First Nation. The FNECP, created in 1999, supports community-based monitoring, research and risk assessment. Since 2000, the national FNECP has funded 103 national projects. Through dietary surveys and chemical exposure assessments and/or human biomonitoring, First Nations collaborated with researchers to gain important information on the chemical safety of their traditional diet. As appropriate, recommendations were made with respect to traditional food consumption. The FNFNES was created in 2008 to fill knowledge gaps on the diet and safety of traditional foods for First Nations living on-reserve south of the 60th parallel. This study was implemented region by region from 2008 to 2018. The FNFNES included five components: household interviews; drinking water sampling for trace metals; hair sampling for mercury; surface water sampling for pharmaceuticals and traditional food sampling for chemical contaminant levels. Results from the FNFNES mercury in hair sampling program will be compared to the findings of the earlier methylmercury biomonitoring program. Results from the FNFNES pharmaceutical sampling results will be explained in relation to how mixtures of pharmaceuticals can be characterized with respect to both their ecological and human health risks.

### **S01.03.12. Total Diet Exposure to Contaminants among First Nations Adults in Canada**

Laurie Chan

*Laurie Chan<sup>1</sup>*

*1. University of Ottawa, Ottawa, ON, Canada.*

Abstract: Indigenous peoples have elevated risks of exposure to environmental contaminants because of their traditional diet as some traditional foods, such as fish, wild game, and birds, have the potential to be contaminated with toxic chemicals. The objective of this study was to estimate dietary exposure to chemical contaminants among First Nations living on-reserve in Canada. A total diet study was constructed based on a 24-hour recall from the First Nations Food, Nutrition, and Environment Study (FNFNES) and contaminant concentrations in foods obtained through FNFNES for traditional foods and Health Canada for market foods. A probabilistic assessment of annual and seasonal traditional food consumption was conducted. This talk will present results from the latest assessments of contaminant exposure among First Nations in Canada and discuss the relationship with their health status.

5. *Community of Winneway - Long Point, Winneway - Long Point, QC, Canada.*
6. *CSSS Tshukuminu Kanani of Nutashkuan, Nutashkuan, QC, Canada.*
7. *Communauté de Unamen Shipu, Unamen Shipu, QC, Canada.*
8. *Commission de santé et de services sociaux des Premières Nations Québec Labrador, Wendake, QC, Canada.*

Abstract: The pilot project Jeunes, Environnement et Santé / Youth, Environment and Health (JES!-YEH!) was conducted in 2015 among children and youth (3-19y, n=198) in collaboration with four First Nation communities in Quebec. Main findings show very low exposure to traditional foods related contaminants (metals and older persistent organic contaminants). However, in some communities, elevated exposure to perfluorononanoic acid (PFNA), bisphenol A, diethylphosphate, monobenzylphtalate and 2,5-dichlorophenol, at higher levels than in the Canadian Health Measure Survey for the same age groups, was found. Food insecurity and overcrowding was important in some communities. Overall, ultra-processed foods and sweet beverages were frequently consumed, and a high prevalence of iron deficiency, anemia, elevated blood manganese and obesity was found. These findings underscore the importance of better understanding the determinants of healthy eating environments in indigenous communities.

## S01.03C. High Resolution Air Pollution Mapping: Translating Data to Action

### S01.03.14. Personal Air Pollution Exposure Tracking: Bringing Data to Users

Roel Vermeulen

*Roel Vermeulen<sup>1</sup>, David Donaire<sup>1</sup>*

*1. IRAS, Utrecht University, Utrecht, Netherlands.*

Abstract: Large scale personal air pollution measurements are currently not feasible due to the lack of robust, affordable and accurate air pollution sensors. However, combining hyper-local air pollution maps with personal tracking information may provide an opportunity to derive personalized exposure estimates. We performed a study in which we overlaid GPS-tracking data (n=120) on time-resolved hyperlocal exposure maps (5 by 5m) of fine particulate matter (PM2.5) and soot (PM2.5 absorbance; PM2.5abs) and compared the derived personal estimates of PM2.5 and PM2.5abs to 24hr residential estimates and personal measurements of PM2.5 and PM2.5abs. The agreement (Concordance Correlation Coefficient) between personal measurements and residential estimates was 0.42 and 0.48 for PM2.5 and PM2.5abs, respectively. The agreement between personal PM2.5 and PM2.5abs estimates based on hyperlocal maps and GPS-tracks and measured personal 24-hr was 0.58 and 0.55, respectively. These results indicate that estimation of personal air pollution based on hyper local maps and GPS-tracks may provide reasonable valid individual predictions of air pollution that may be more accurate than only relying on air pollution estimates at the residential address. To facilitate personal air pollution tracking we have developed an App that allows near-real-time coupling of time-resolved air pollution maps with GPS-tracks. Such personalized information on air pollution can be used to inform the general and patient populations on air pollution conditions allowing for individual choices on when to undertake activities and where. In addition, the App allows users to report back on the living environment and their experiences, in order to update the information and to develop maps of perceived conditions of the living environment.

### **S01.03.15. Community Use of Stationary and Mobile Pollution Monitors in Somerville and Metropolitan Boston MA USA**

Wig Zamore

*Wig Zamore<sup>1</sup>*

*1. Somerville Transportation Equity Partnership, Somerville, MA, United States.*

Abstract: Over the last fifteen years, advocacy groups in Somerville and nearby communities have worked with environmental health research scientists and graduate students to study local air pollution and, more recently, noise patterns. These efforts can help inform community partners, policy leaders and regulatory agencies about serious environmental health risks. The results can help with land use and transportation decisions, and mitigation needs. Our community-based projects have ranged from short student practicums to formal multi-year research projects funded by NIH, EPA, HUD and Kresge Foundation. The practicums that we have engaged in have included consideration of turf vs natural athletic field exposures, lead in children's jewelry, community garden soil safety, bicyclist exposures and aviation noise patterns. In Somerville, a city of 80,000 with intense highway and diesel commuter rail exposures, we had the advantage of early near roadway pilot projects that used time integrated Nitrogen Oxide passive monitors and the Aerodyne Research mobile lab to show steep gradients of transportation related gases and ultrafine particle concentrations. This research, and public health records that showed a high correlation between surface transportation intensity and excess lung cancer and heart attack deaths, alerted us to the serious nature of transportation pollution. And to the need to bring local environmental health concerns to the forefront in policy and project decisions. Over the last decade we have also been engaged with Tufts and other universities in a series of near roadway research programs known as the Community Assessment of Freeway Exposure and Health (CAFEH). CAFEH has relied on intense mobile monitoring, assisted by stationary monitors, with a special focus on Ultrafine Particles, to relate biomarkers of cardiovascular risk in small populations to transportation sources. This research approach is difficult and might benefit from similar efforts at greater scale.

### **S01.03.16. Reducing Exposures to Traffic-Related Air Pollution in Urban Areas: Regional Planning, Neighborhood Design, and Individual Behavior**

Marianne Hatzopoulou

*Marianne Hatzopoulou<sup>1</sup>, Maryam Shekarrizfard<sup>1</sup>, Sabreena Anowar<sup>2</sup>, Naveen Eluru<sup>2</sup>, Audrey Smargiassi<sup>3</sup>, Louis Francois Tetreault<sup>3</sup>, Patrick Morency<sup>4</sup>, Celine Plante<sup>4</sup>, Shamsunnahar Yasmin<sup>2</sup>, Ahmedreza Faghih Imani<sup>1</sup>, Louis Drouin<sup>4</sup>, Sophie Goudreau<sup>4</sup>*

- 1. Civil Engineering, University of Toronto, Toronto, ON, Canada.*
- 2. University of Central Florida, Orlando, FL, United States.*
- 3. Universite de Montreal, Montreal, QC, Canada.*
- 4. Direction Régionale de Sante Publique du CIUSS du Centre-Sud-de-l'Ile de Montreal, Montreal, QC, Canada.*

**Abstract:** The assessment of exposure to traffic-related air pollution has seen advances along various dimensions. Air pollution dispersion models with fine spatial resolution and ability to reflect near-road air quality in street canyons, have made possible the development of exposure surfaces associated with strategic long-range scenarios affecting land-use and transportation in urban areas. Meanwhile, personal monitoring and GPS-enabled applications have motivated the development of a wide range of tools intended to inform users of their own exposure and ways to reduce it. While scientific evidence points to the success of these tools in identifying measures, at the policy or personal level, able to reduce air pollution exposures, there much left to learn about the impact of these tools on human behavior. How do policy makers use scenario-based information on air quality to formulate policy decisions? And how do individuals respond to air quality information provided to them? Are there individuals more inclined to respond to exposure reduction advice in a positive manner? This presentation will detail how high resolution air pollution data has informed a range of interventions to reduce traffic-related air pollution exposures in Canadian cities, from clean routes applications to large investments in transportation infrastructures and urban design. New evidence will also be presented from a stated-preference experiment examining how air pollution information impacts individual behavior.

### **S01.03.17. Street-Level Air Pollution, Health Disparities, and Advocacy**

Maria Harris

*Maria H. Harris<sup>1</sup>, Brian Beveridge<sup>2</sup>, Margaret Gordon<sup>2</sup>, Fern Uennatornwarangoon<sup>1</sup>, Gabriela Zayas del Rio<sup>1</sup>, Ananya Roy<sup>1</sup>*

*1. Environmental Defense Fund, San Francisco, CA, United States.*

*2. West Oakland Environmental Indicators Project, Oakland, CA, United States.*

**Abstract:** Recent mobile monitoring and high density distributed network campaigns have provided unprecedented insight into intra-neighborhood air pollution variability in Oakland, CA. A study examining these data in relation to health records found that elderly residents with higher levels of traffic-related pollution in the immediate vicinity of their homes had elevated cardiovascular risks. West Oakland Environmental Indicators Project, a local environmental justice organization, in partnership with Environmental Defense Fund, a large environmental non-profit, is leading efforts to use these findings to influence community, city, and state level efforts to address harmful air pollution. Several important learnings have emerged from our work to date. First, community residents with experiential understanding of local air pollution sources are key partners in interpreting hyperlocal pollution data. Community partners are also the most credible and trusted communicators of data to local residents, and the most effective advocates for local policy change. Second, messaging around air pollution-related health impacts and inequities at the street and block level can be particularly effective in engaging a broad range of stakeholders. Findings must be communicated in clear and compelling terms, and "scientific interpreters" can help accurately represent scientific findings in suitable language and formats. Finally, efforts to translate study results to action require long-term commitment and follow-through - preliminary data and findings should be shared with community partners as early as possible and ongoing support and collaboration must continue long after research is completed. These elements: trust-based partnerships with local advocates, effective communication, and long-term engagement, require substantial investment of resources beyond those required to conduct traditional research, but are core to enabling translation of hyperlocal air pollution data to action.

### **S01.03.18. Rapid-Response Local Monitoring of Toxic Air Pollution after Hurricane Harvey**

Anthony Miller

*Anthony E. Miller<sup>1</sup>, Elena Craft<sup>2</sup>*

*1. Entanglement Technologies, BURLINGAME, CA, United States.*

*2. Environmental Defense Fund, Austin, TX, United States.*

**Abstract:** Natural disasters pose unique chemical exposure risks. In August of 2017, Hurricane Harvey slammed into Houston, dumping 275 trillion tons of water that flooded the Houston area. As the Houston area is home to roughly 570 chemical plants, 43 Superfund sites, nine refineries, 188 cement batch plants, 80 metal recycling facilities, one of the largest ports in the nation, and the 25-mile long Houston Ship Channel, the flood damage was severe. As a result, Houston's petrochemical industry released millions of pounds' worth of harmful pollution into the air. The state agency responsible for protecting the environment in Texas had shut down equipment measuring air contaminants in an attempt to protect air quality monitors from storm-related water and wind damage. The region's lack of zoning laws means that many industrial facilities in the region sit adjacent to schools and residential neighborhoods. With state and federal air pollution monitors off-line because of the storm, Environmental Defense Fund hired Entanglement Technologies to deploy a prototype AROMA analyzer to perform mobile surveys of atmospheric volatile organic carbons (VOCs) in areas where storm-related pollution releases had been reported. AROMA provided a real-time speciated VOC analysis. The mobile survey identified two significant plumes of benzene, a known carcinogen, and several additional plumes with lower toxicological risk. Field measurements identified source areas, provided exposure information for impacted residential areas, and assessed the impact of variable atmospheric conditions on dispersion of pollutants. AROMA measurements corroborated measurements taken by the City of Houston and resulted in an ongoing investigation of a petrochemical facility for underreporting of emissions and permit violations. This mobile campaign demonstrated the value of high resolution, rapid response data for allocating scarce government measurement resources to protect impacted communities.

## 001.04A. Air Pollution, Asthma and Allergic Disease

### **001.04.01. Association of Air Pollution with Incidence of Asthma, Allergic Rhinitis and Eczema: 10-Year Follow-Up of the Toronto Child Health Evaluation Questionnaire (T-CHEQ) Study**

Dave Stieb

*Teresa To<sup>2</sup>, Natasha Gray<sup>2</sup>, Jingqin Zhu<sup>2</sup>, Dave Stieb<sup>1</sup>, Sharon Dell<sup>2</sup>*

*1. Health Canada, Vancouver, BC, Canada.*

*2. Hospital for Sick Children, Toronto, ON, Canada.*

**Abstract:** Objective: To examine the associations between ambient nitrogen dioxide (NO<sub>2</sub>) and ozone (O<sub>3</sub>) exposures at birth and incidence of asthma, allergic rhinitis and eczema in childhood through adolescence. Methods: In the 2006 Toronto Child Health Evaluation Questionnaire study, 5,619 children aged 5-9 were recruited from randomly-selected public schools in Toronto, Ontario. Participants were included in this study if they were born in Ontario and consented to have their health card number used for data linkage. Yearly mean values of NO<sub>2</sub> and O<sub>3</sub> were acquired from air pollution fixed monitoring stations and assigned to participants based on their postal codes at birth, using inverse distance weighting. The primary outcome, physician-diagnosed asthma, was measured using a validated health administrative definition. Secondary outcomes, allergic rhinitis and eczema, were measured by any health services use for these conditions. Participants were followed from birth until outcome, March 31, 2016, or loss-to-follow-up. Multivariable Cox proportional hazard regression models were used to estimate the associations between air pollutants and outcomes, adjusting for potential confounding variables. Results: 1,881 children were followed from birth for an average of 13 years. 31% of children developed asthma; average age at asthma incidence was 3 years. A 10-unit increase in exposure to O<sub>3</sub> at birth was associated with an 82% increased hazard of asthma (HR: 1.82; 95%CI: 1.05, 3.18), while exposure to NO<sub>2</sub> was not associated with asthma (HR: 1.02; 95%CI: 0.53, 1.98). O<sub>3</sub> was also associated with increased hazard of allergic rhinitis and eczema. Conclusion: Ambient O<sub>3</sub>, but not NO<sub>2</sub>, was associated with a significantly increased risk of incident asthma, allergic rhinitis and eczema. This suggests that improving air quality and increasing awareness about the risks of air pollution may have beneficial effects on the prevention of asthma and other allergic disease.

**Abstract:** Background: How early-life and current exposures to air pollution affect allergic and respiratory health development remains unclear. Objective: We examined associations between traffic-related air pollution levels and childhood eczema, rhinoconjunctivitis and asthma prevalences in 4 European birth cohorts from 6 centers (EDEN, INMA (Sabadell, Gipuzkoa, Valencia), RHEA and ROBBIC-Rome). Methods: Eczema, rhinoconjunctivitis and asthma were assessed in children aged 4 (N =4262 from 6 centers) and 7/8 years-old (N =3365 from 5 centers) using MeDALL-harmonized outcome definitions. A multi-morbidity outcome (any condition versus none) was also defined. Land-use regression models, based on air pollution monitoring data collected near the time of cohort recruitment, were used to estimate individual outdoor levels of nitrogen dioxide (NO<sub>2</sub>), nitrogen oxides, particulate matter with an aerodynamic diameter < 10 µm, between 10 µm and 2.5 µm, and < 2.5 µm (PM<sub>2.5</sub>), as well as PM<sub>2.5</sub> absorbance, to the birth, 4- and 7/8-year home addresses. Cohort-specific associations were assessed using adjusted logistic regression models and combined in a random effects meta-analysis. Results: Overall, the estimated air pollutants and health outcomes were not associated, regardless of the age or home address considered (e.g. meta-analysis odds ratios [95% confidence intervals] for asthma at 4 and 7/8 years were 0.85 [0.67, 1.06] and 0.96 [0.71, 1.30] per 10 µg/m<sup>3</sup> increase in NO<sub>2</sub> estimated to the birth address, respectively, and 0.81 [0.41, 1.59] and 0.58 [0.28, 1.20] per 5 µg/m<sup>3</sup> increase in PM<sub>2.5</sub> estimated to the birth address, respectively). We observed little heterogeneity across cohorts. Conclusion: Despite reducing outdoor exposure misclassification at the home address by using air pollution estimates derived from data

collected near the time of birth, we did not find associations between traffic-related air pollution levels and childhood eczema, rhinoconjunctivitis or asthma prevalences.

### **O01.04.03. Effects of Fine Particulate Matter and Its Constituents on Asthmatic and Allergic Symptoms in Preschool Children: A Cross-Sectional Study in Six Cities of China**

Wenming Shi

*Wenming Shi<sup>1</sup>, Cong Liu<sup>1</sup>, Chen Huang<sup>2</sup>, Haidong Kan<sup>1</sup>, Zhuohui Zhao<sup>1</sup>*

*1. Department of Environmental Health, School of Public Health, Shanghai, China.*

*2. School of Environment and Architecture,, Shanghai, China.*

**Abstract:** Background/Aim: Few studies examined the effects of specific PM<sub>2.5</sub> constituents on childhood asthma and allergy in China. We aimed to investigate the effects of various PM<sub>2.5</sub> constituents on asthmatic and allergic symptoms in preschool children in China. Methods: A cross-sectional study was conducted among 48219 preschool children in six cities (Shanghai, Nanjing, Chongqing, Changsha, Urumqi and Taiyuan) based on China , Children ,Home and Health (CCHH) project in China. Information on allergic symptoms as well as demography were collected by questionnaires. Data for ambient PM<sub>2.5</sub> concentration and its 5 constituents: BC, NH<sub>4</sub><sup>+</sup>, SO<sub>4</sub><sup>2-</sup>, NO<sub>3</sub><sup>-</sup> and OC were obtained from the global burden disease project to 205 kindergartens at a spatial resolution of 0.01×0.01(1km×1km) in six cities. A hierarchical logistic regression model was performed to explore the associations between kindergarten-level PM<sub>2.5</sub> components and individual-level outcomes of asthmatic and allergic symptoms controlling for demography and other covariates. Results: A total of 30759 participants (51.7% male) were finally completed the study due on the missing data. Both the single-pollutant and two-pollutants model showed that ambient PM<sub>2.5</sub> per 10ug/m<sup>3</sup> increase positively associated with the prevalence of diagnosed asthma by an adjusted odds ratio (AOR) and 95% confidence interval(CI) of 1.18(1.01-1.35) and 1.13(1.02-1.24), respectively. Furthermore, the concentration of SO<sub>4</sub><sup>2-</sup> and NO<sub>3</sub><sup>-</sup> were significantly associated with the prevalence of asthma and current rhinitis by the AOR for each 1ug/m<sup>3</sup> increase in SO<sub>4</sub><sup>2-</sup>, and NO<sub>3</sub><sup>-</sup> concentrations of 1.09(1.03-1.15) for asthma and 1.04(1.00-1.07) for current rhinitis, respectively. Conclusion: Components of PM<sub>2.5</sub>, especially NO<sub>3</sub><sup>-</sup> and SO<sub>4</sub><sup>2-</sup> exposure were associated with asthmatic and allergic diseases in preschool children in China. Considering the related sources and combustion, it may represents an preventable risk factor for childhood asthma and allergic diseases.

#### **O01.04.04. Exposure to Traffic-Related Air Pollution and Risk of Development of Childhood Asthma: Results from the Born in Bradford Cohort Study**

Haneen Khreis

*Haneen Khreis<sup>1</sup>, Marta Cirach<sup>2</sup>, Ana Espinosa<sup>2</sup>, Brian Kelly<sup>3</sup>, John Wright<sup>3</sup>, Rosemary R. McEachan<sup>3</sup>, Joe Zietsman<sup>1</sup>, Mark Nieuwenhuijsen<sup>2</sup>*

- 1. Texas A&M Transportation Institute (TTI) and Center for Advancing Research in Transportation Emissions, Energy, and Health (CARTEEH), College Station, TX, United States.*
- 2. ISGlobal, Centre for Research in Environmental Epidemiology (CREAL), Barcelona, Spain.*
- 3. Bradford Institute for Health Research, Bradford Teaching Hospitals Foundation Trust, Bradford, United Kingdom.*

**Abstract:** Background Childhood exposure to traffic-related air pollution (TRAP) might lead to the onset of new childhood asthma. However, there has been little study of the modifying effect of ethnicity especially among South Asians. We aimed to evaluate the relationship between residential exposure to TRAP and new-onset asthma in the multi-ethnic Born in Bradford cohort study. **Methods** Using validated land-use regression models developed in the ESCAPE project (European Study of Cohorts for Air Pollution Effects), we estimated annual average childhood exposures to NO<sub>2</sub>, NO<sub>x</sub>, PM<sub>2.5</sub>, PM<sub>2.5</sub> absorbance, PM<sub>10</sub>, and PM<sub>coarse</sub> at the birth residence. As another TRAP exposure metric, we also estimated traffic intensity within 100m buffer and traffic intensity on the nearest major road. New childhood asthma cases were identified based on diagnostic codes entered by general practitioners onto the primary care databases of the 11032 eligible children. We used Cox proportional hazard models, adjusted for key confounders, to evaluate the relationship between residential exposure to TRAP and new-onset asthma. We then stratified the analysis by the mother's ethnic group. **Results** We found multiple positive and statistically significant associations between the exposure to the different pollutants and the new onset of asthma. The associations with the traffic intensity indicators were null. Stratifying the analysis by "White British" and "Pakistani" ethnicities revealed that the associations were stronger or restricted to the Pakistani children. This was especially prominent in association with the exposure to PM<sub>2.5</sub> absorbance, a specific traffic marker. **Conclusion** Our results suggest that associations between TRAP exposures and new-onset asthma differ between White British and Pakistani origin infants.

Abstract: Research suggests that environment plays a significant role in the presentation of eosinophilic esophagitis (EoE), an allergic disease affecting the esophagus, resulting in inflammation and esophageal symptoms. Aeroallergens are known to exacerbate EoE. Additional aeroantigens, such as air pollution, have been postulated to exacerbate EoE. We examined emergency department (ED) visits among EoE patients and acute exposures to ambient particulate air pollution (PM2.5). Retrospective case crossover analyses of ED visits among EoE patients (January 2000 - May 2014) were performed using data from the Utah Population Database, University of Utah Health Sciences Center, and Intermountain Healthcare and ambient air pollution data. Two separate methods were used to estimate PM2.5 exposure: 1) kriging of local monitoring stations and 2) assigning the observations from the closest monitor (limited to EoE patients living within a pre-specified distance to the closest monitor). We controlled for ozone, nitrogen dioxide, and temperature. The cohort included 4,381 EoE patients, 242 of whom had ED visits. The odds ratio (OR) of ED visit among EoE patients for chest pain, dysphagia, and/or esophageal impaction with PM2.5 above 35 µg/m<sup>3</sup> on at least one day during the preceding week was 2.79, 95% confidence interval (CI) 1.04-7.46 using the kriging method for 131 ED visits that could be assigned PM2.5 data. Using the closest monitor estimation method, the OR was 2.96, 95% CI 1.07-8.25 for 76 ED visits that could be assigned PM2.5 data. Restricting the analysis to ED visits for dysphagia and/or impaction were significant for the kriging method, but not closest monitor. In this study using individual-level case-crossover analysis, we find evidence that acute exposures to PM2.5 is associated with exacerbations of EoE. Further research into the effects of air pollution on EoE is warranted, with careful consideration of the method used to assign pollution data to patient data.

## O01.04B. Application of Machine Learning Methods to Develop Spatiotemporal Models of Air Pollution

### **O01.04.06. Generalization of Constrained Mixed-Effect Modeling Framework with Ensemble Learning to Broader Geographic Areas for Predicting Nitrogen Oxides at High Spatiotemporal Resolution**

Rima Habre

*Lianfa Li<sup>1</sup>, Mariam S. Girguis<sup>1</sup>, Frederick Lurmann<sup>2</sup>, Jun Wu<sup>3</sup>, Robert Urman<sup>1</sup>, Ed Rappaport<sup>1</sup>, Beate Ritz<sup>4</sup>, Meredith Franklin<sup>1</sup>, Carrie Breton<sup>1</sup>, Frank Gilliland<sup>1</sup>, Rima Habre<sup>1</sup>*

**Abstract:** Background: Spatiotemporal models developed for a specific region typically provide high spatial and temporal resolution in predicting exposures locally; however, it is challenging to directly apply them to broader regions in large epidemiological studies. Aim: To extend our southern California (CA) nitrogen oxides (NO<sub>x</sub>) spatiotemporal modeling framework (Li et al., 2017) to the entire state, evaluate its performance, and recommend key parameters to tune for future spatiotemporal model extension applications. Methods: In addition to our southern CA model data, we incorporated data from 105 ambient monitoring stations to cover CA. We conducted sensitivity analyses to determine the optimal number and aggregation distance to use in reconstructing temporal basis functions (temporal variability) and Thiessen polygons (spatial effects), respectively. We conducted ensemble and 10-fold cross validation (CV) to determine model prediction performance against from long-term ambient monitoring data and from short-term independent measurement campaigns. Results: We achieved an ensemble learning CV R<sup>2</sup> of 0.88 for both our NO<sub>2</sub> and NO<sub>x</sub> CA-wide global models. Without considering regional differences, global models had slightly diminished performance (R<sup>2</sup> reduced ~9% for NO<sub>2</sub> and 4% for NO<sub>x</sub>) than region-specific models for southern CA. Sensitivity analyses showed that 4-6 temporal basis functions and a smaller aggregation distance (200 m) ensured that the global model captured a wider range of temporal and spatial patterns in NO<sub>2</sub> and NO<sub>x</sub> variability, respectively. Additional temporal basis functions may result in overfitting and smaller aggregation distances severely impact computational time with minor incremental improvement in model performance. Conclusions: This study illustrates the importance of accounting for regional differences for tuning local, region-specific models such that they can be applied to larger areas.

### **001.04.07. An Ensemble Machine-Learning Model to Predict Historical PM2.5 Concentrations in China from Satellite Data**

**Abstract:** Background: The long satellite aerosol data record enables assessments of historical PM2.5 level in developing countries such as China where routine PM2.5 monitoring began only recently. However, most previous models reported decreased prediction accuracy when predicting PM2.5 levels outside the model-training period. This limitation greatly hinders the application of satellite-driven exposure assessments in the research on health effects of long-term PM2.5 exposure. Objectives: We proposed an ensemble machine learning approach that provided reliable PM2.5 hindcast capabilities in China. Methods: Non-random missing satellite data due to cloud cover were first filled by multiple imputation to ensure unbiased long-term exposure estimates. Then the modeling domain, China, was divided into seven regions using a spatial clustering method to control for unobserved spatial heterogeneity. A set of machine learning models including random forest, generalized additive model, and extreme gradient boosting were trained in each region separately. Finally, a generalized additive ensemble model was developed to combine predictions from different algorithms. Results: The ensemble prediction characterized the spatiotemporal distribution of daily PM2.5 well with the cross-validation (CV) R2 (RMSE) of 0.79 (21  $\mu\text{g}/\text{m}^3$ ). The cluster-based sub-region models outperformed national models and improved the CV R2 by  $\sim 0.05$ . Compared with previous studies, our model provided more accurate hindcasts at the daily level (R2 = 0.53, RMSE = 28  $\mu\text{g}/\text{m}^3$ ) and monthly level (R2 = 0.81, RMSE = 13  $\mu\text{g}/\text{m}^3$ ). Conclusions: Our hindcast modeling system allows for the construction of long-term, unbiased historical PM2.5 levels that can support epidemiologic studies on the chronic health effects of PM2.5 in China.

#### **O01.04.08. Leveraging Google Place of Interest (POI) Data, Crowdsourcing, and Machine Learning to Predict Urban NO<sub>2</sub> Concentrations for the Contiguous U.S.**

Tianjun Lu

*Tianjun Lu<sup>1</sup>, Wenwen Zhang<sup>1</sup>, Steve Hankey<sup>1</sup>*

*1. Virginia Tech, Blacksburg, VA, United States.*

**Abstract:** Background: Land Use Regression (LUR) has been extensively applied to model intra-urban variations of air quality across the US. Predictor variables are typically derived from government sources (e.g., US Census) and do not include detailed information on land use or urban form. We developed LUR models that combine enhanced data on urban form and land use with machine learning to compare to traditional LUR models. Methods: Our LUR models are based on data from three sources: (1) a crowdsourced measure of urban form, (2) land use information derived from Google Place of Interest (POI) data, and (3) satellite observations of air quality. We developed models using US EPA NO<sub>2</sub> monitoring data (n=426 locations) during 2010-2015. The measure of urban form (Local Climate Zones [LCZs]) was obtained using a crowdsourcing platform (Amazon Mechanical Turk) to allow multiple users (n=10) to classify satellite imagery into 17 categories of urban development (e.g., compact; sprawl). We web-scraped Google POI data (e.g., gas stations; restaurants) at various buffers (100-1,000 meters) to add detailed information on land use. We also included satellite observations of NO<sub>2</sub> abundance. Using only these variables, we developed LUR models using both conventional (stepwise regression) and machine learning (e.g., bagging; gradient boosting). Results: Model fit was better for the machine learning models (gradient boosting; R<sup>2</sup>: 0.59; mean absolute error [MAE]: 2.46) as compared to the conventional models (i.e., stepwise regression; R<sup>2</sup>: 0.39 and MAE: 3.35) when using only the LCZ urban form measure and satellite NO<sub>2</sub> abundance. Adding Google POI data improved model fit. For gradient boosting model-R<sup>2</sup> increased to 0.65 (MAE: 2.28); model-R<sup>2</sup> increased to 0.61 for stepwise regression (MAE: 2.34). Conclusions: Our work suggests that using generalizable data on urban form (e.g., Google POI; LCZs) to develop LUR models may produce similar results to models developed using conventional data sources.

## **O01.04.09. Developing Advanced PM2.5 Exposure Models in Lima, Peru**

Bryan Vu

*Bryan N. Vu<sup>1</sup>, Jianzhao Bi<sup>1</sup>, Yang Liu<sup>1</sup>*

*1. Environmental Health, Emory University, Decatur, GA, United States.*

**Abstract:** Background: There is convincing evidence of adverse health effects induced by exposure to PM2.5 in the growing body of literature. Lima's topography and aging vehicular fleet results in severe air pollution with limited amounts of monitors to effectively quantify measurements for epidemiologic studies. Objectives: We propose to develop a high-performance satellite-driving exposure model to estimate daily PM2.5 concentrations at a 1 km spatial resolution in Lima, Peru from 2010 to 2016 using a combination of ground measurements, aerosol optical depth (AOD), meteorological fields, parameters from atmospheric chemical transport models, and land use variables. Methods: Parameters from the Weather Research and Forecasting model coupled with Chemistry (WRF-CHEM) and the European Centre for Medium-Range Weather Forecasts (ECMWF) were evaluated against ground monitoring stations from Weather Underground. A random forest model was used to gap-fill non-random missing satellite AOD data due to cloud cover to enhance spatial coverage and quality. Both a linear mixed effects model and a random forest model was used to fit AOD, WRF-CHEM, ECMWF, meteorological fields, and land use parameters against ground measurements from 16 monitoring stations with available data between 2014 to 2016. Both models were then used to estimate daily PM2.5 concentrations from 2010 to 2016. Results: The overall cross-validation (CV) R2 value and (RMSE) for the linear mixed effects model and random forest model was 0.58 (7.08 µg/m3) and 0.73 (5.66 µg/m3), respectively. The random forest model's robust ability to include more parameters outperformed the linear mixed effects model due to limited number of ground observations. Conclusions: Our models allow for construction of long-term historical daily PM2.5 levels to support fundamental and imperative epidemiological studies that will likely impact governmental policies on air quality in Lima, Peru.

#### **001.04.10. Assessment of Shared and Unshared Exposure Measurement Error in Ensemble Learning Estimates of Nitrogen Oxides and Its Implications on Epidemiological Findings in Air Pollution Studies**

Mariam Girguis

*Mariam S. Girguis<sup>1</sup>, Lianfa Li<sup>1</sup>, Frederick Lurmann<sup>2</sup>, Jun Wu<sup>3</sup>, Robert Urman<sup>1</sup>, Ed Rappaport<sup>1</sup>, Carrie Breton<sup>1</sup>, Frank Gilliland<sup>1</sup>, Daniel Stram<sup>1</sup>, Rima Habre<sup>1</sup>*

- 2. Sonoma Technology Inc., Petaluma, CA, United States.*
- 3. Public Health, University of California College of Health Sciences, Irvine, CA, United States.*

**Abstract:** To improve exposure spatial and temporal resolution, researchers are using machine learning spatiotemporal air pollution models for large cohort studies. We aim to (1) measure shared, unshared, multiplicative, and additive (SUMA) measurement error in a three-stage (mixed effect ensemble learning with constrained optimization) spatiotemporal nitrogen oxides (NO<sub>x</sub>) model and (2) assess the impact of shared error and advanced exposure algorithms on epidemiological results. By treating NO<sub>x</sub> ensembles as realizations from an external dosimetry system, we quantified SUMA measurement error by extracting variance and covariance elements across realizations. To identify geographic locations with significantly elevated error, we used generalized additive models with a smooth term for location. We iteratively analyzed the risk of recent wheeze and NO<sub>x</sub> exposure among children using predictions from each stage of the NO<sub>x</sub> model to assess incremental influences of modeling stages on epidemiological conclusions and adjusted for shared error. We found evidence of both shared and unshared multiplicative error ( $p < 0.01$ ) in our spatiotemporal NO<sub>x</sub> predictions. Findings indicate that unshared multiplicative error is 25.8 times larger than the shared multiplicative error. Significant geographic variation of shared multiplicative error was observed ( $p = 0.0004$ ) and the majority (41%) of all predictions with high shared multiplicative error were observed in the earliest prediction period, 1992-2000. Depending on the exposure output used, the wheeze odds ratio for an interquartile range increase in NO<sub>x</sub> exposure ranged from 1.16-1.29. The standard error increased from 0.0049 to 0.0053 when accounting for shared multiplicative error. Spatial and temporal patterns of shared multiplicative error were mostly observed in densely populated urban regions with complex air pollution sources. Epidemiological conclusions were minimally affected by shared multiplicative exposure measurement error.

## 001.04C. Neurological and Cognitive Outcomes Associated with Air Pollution

### **001.04.11. Brain Metabolite Levels May Mediate Traffic-Related Air Pollution Associated Generalized Anxiety Symptoms: Findings from the Cincinnati Childhood Allergy and Air Pollution Study**

Kelly Brunst

*Kelly J. Brunst<sup>1</sup>, Kim Cecil<sup>2</sup>, Mekibib Altaye<sup>3</sup>, Travis Beckwith<sup>2</sup>, Kimberly Yolton<sup>4</sup>, Grace LeMasters<sup>1</sup>, Patrick Ryan<sup>3</sup>*

- 4. General and Community Pediatrics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, United States.*

**Abstract:** Introduction: Exposure to traffic-related air pollution (TRAP) is associated with cognitive and neurobehavioral outcomes. The impact of TRAP on brain metabolism and the role of these in childhood anxiety is unknown. Methods: Adolescents (N=145, aged 11-15 years) underwent neuroimaging as part of the Cincinnati Childhood Allergy and Air Pollution Study. Brain metabolite levels- including myoinositol (mI), N-acetylaspartate (NAA), creatine (Cr), choline (Cho), glutamate (Glu), glutamate plus glutamine (Glx), glutathione (Gsh) - were measured in the anterior cingulate cortex using magnetic resonance spectroscopy (MRS). The Spence Children's Anxiety Scale assessed generalized anxiety symptoms. Average exposure to TRAP during the last 12 months was estimated using a validated land use regression model. Linear regression was used to assess TRAP effects on brain metabolite levels and anxiety symptoms. A bootstrapping method was used to test for mediation by brain metabolite levels. Models were adjusted for race, family income, maternal age at delivery and depression, hair cotinine, and parental relation frustration. Results: High TRAP exposure (> 75th %) was associated with significant increases in Glx ( $\beta = 0.62$ ; 95%CI 0.06, 1.18), Glu ( $\beta = 0.32$ ; 95%CI 0.04, 0.60), Cho ( $\beta = 0.08$ ; 95%CI 0.01, 0.15), and mI ( $\beta = 0.25$ ; 95%CI 0.01, 0.50) compared to low TRAP exposure ( $\leq 75$ th %). High TRAP exposure ( $\beta = 3.47$ ; 95% CI 0.62, 6.33) and increased mI levels ( $\beta = 2.09$ ; 95% CI 0.21, 3.96) were significantly associated with more generalized anxiety symptoms. The mediation analysis suggests that 13% of the total effect between TRAP and generalized anxiety symptoms was mediated by mI levels ( $\beta$  indirect effect = 0.43; 95% CI 0.41, 0.46). Conclusions: TRAP-associated increases in metabolite levels suggest possible excitatory neurotransmission, membrane disruption, active gliosis, and inflammation. Disruption in mI levels might be an important pathway linking TRAP and anxiety in adolescents.

## **O01.04.12. Effects of Traffic Related Particulate Matter on Behavior, Inflammation, and Neuronal Tract Integrity in a Developmental Rodent Model**

*2. Public Health and Community Medicine, Tufts University School of Medicine, Boston, MA, United States.*

*3. Civil and Environmental Engineering, Tufts University School of Engineering, Somerville, MA, United States.*

Abstract: There is convincing evidence that living close to major roadways and highways is associated with increased morbidity and mortality. Data indicate that traffic-related air pollution (TRAP) contributes to these adverse health outcomes near traffic sources, and particulate matter (PM) is elevated in TRAP. Animal toxicology studies as well as recent human epidemiology suggest that exposure to PM affects cardiovascular health and the nervous system. There is increasing epidemiological evidence of neurological effects including white matter loss, impaired cognition in the young and old, depression and anxiety, and teenage delinquency. Etiologically relevant animal studies can strengthen the case for the biological plausibility of these epidemiological associations. Therefore, we have recently developed a novel rodent model of developmental exposure to TRAP associated PM where gestating and lactating rats are chronically exposed (5 hrs/day, 5 days/week for 6 weeks) to epidemiologically relevant levels of PM (PM<sub>2.5</sub> and UFP, <100nm) from Boston area traffic tunnels. Following this exposure, the behavior, peripheral immune activity, and neuroanatomy (with ex vivo anatomical and diffusion tensor neuronal track targeted MRI) of juvenile male offspring were assessed. Compared to low ambient PM exposed controls, TRAP PM exposed offspring exhibited increased fear/anxiety ( $p=0.04$ ,  $d=1.0$ ,  $p<0.01$ ,  $d=1.6$ ), impaired group ( $p<0.01$ ,  $d=1.5$ ) and pairwise ( $p=0.04$ ,  $d=0.9$ ) social behavior, deficient nest building ( $p=0.04$ ,  $d=1.0$ ), an altered gastrointestinal response to novelty stress ( $p<0.01$ ,  $d=1.4$ ), and changes in neuronal tract integrity. Immune assessments are ongoing. It is concluded that this is a valuable naturalistic model to test the adverse effects of TRAP PM on neurobehavioral health, and increased research on neuroendocrine/neuroinflammatory mechanisms is warranted.

### **O01.04.13. The Role of Cardiovascular Disease in the Relationship of Chronic Exposure to Air Pollution and Incident Dementia**

Sindana Ilango

*Sindana Ilango<sup>2</sup>, Hong Chen<sup>1</sup>, Tarik Benmarhnia<sup>2</sup>*

*1. Public Health Ontario, Toronto, ON, Canada.*

*2. Family Medicine and Public Health, UCSD, La Jolla, CA, United States.*

**Abstract:** **BACKGROUND:** Cardiovascular disease is a known determinant of dementia. Epidemiologic studies have also shown that chronic exposure to air pollution may play a role in the development of dementia and cardiovascular disease. This motivated us to apply a formal causal mediation analysis to examine the relative contribution of cardiovascular disease to the relationship between air pollution and incident dementia. **METHODS:** A population-based cohort comprised of Canadian-born residents of Ontario, Canada who participated in the Canadian Community Health Surveys from 1996-2003 were followed through 2013 or until dementia diagnosis. Chronic exposure to selected ambient air pollutants (i.e., fine particulate matter [PM<sub>2.5</sub>] and nitrogen dioxide [NO<sub>2</sub>]) was assessed using a 3-year running average with a 5-year lag before dementia diagnosis. Incident cardiovascular disease occurring prior to dementia was evaluated as a potential mediator. We used multi-level Cox proportional hazard regression models, adjusting for individual- and neighborhood-level risk factors (e.g., smoking, physical activity, education, and neighborhood income), to estimate hazard ratios (HR) for every interquartile range increase in exposure to PM<sub>2.5</sub> and NO<sub>2</sub>. We estimated the total, direct, and indirect effects of air pollution on incident dementia and the proportion mediated through cardiovascular disease. **RESULTS:** The risk of dementia was moderately higher among those exposed to NO<sub>2</sub> (HR=1.08 95% CI=1.00, 1.16) and PM<sub>2.5</sub> (HR=1.15 95% CI=0.93, 1.41) after adjusting for covariates. We estimate 9.0% and 21% of the observed association between NO<sub>2</sub> and PM<sub>2.5</sub>, respectively, and dementia to be mediated through cardiovascular events. **CONCLUSION:** These results suggest that some of the association between chronic air pollution and dementia is mediated through its effect on cardiovascular disease. Improving cardiovascular health may prevent dementia in areas with higher exposure to air pollution.

## O01.04D. Novel Approaches in Environmental Epidemiology

### **O01.04.15. Case Time Series: A Novel Study Design for Big Data Analyses in Environmental Epidemiology**

Antonio Gasparrini

*Antonio Gasparrini<sup>1</sup>, Ana Maria Vicedo-Cabrera<sup>2</sup>, Francesco Sera<sup>2</sup>*

*1. Centre for Statistical Methodology, London School of Hygiene & Tropical Medicine, London, United Kingdom.*

*2. Department of Public Health, Environments and Society, London School of Hygiene & Tropical Medicine, London, United Kingdom.*

**Abstract:** Environmental research has been transformed by big data technologies, such as electronic health records linkage, wearables and remote sensing. These tools provide the opportunity to perform large population-based studies, with longitudinal collection of individual-level variables and finely reconstructed spatio-temporal exposure maps. However, these studies require innovative analytical methods. Here we present a new study design called case time series for investigating transient health risks in epidemiological analyses. The design is based on the reconstruction of longitudinal profiles of health outcomes and time-varying predictors in subject-specific series. This adaptable framework combines the individual-level setting and confounding control of case-only methods, such as case-crossover and self-controlled case series, with the flexibility and temporal structure of time series methods to model trends and lagged effects. It is applicable with either continuous or (multiple) event outcomes. Estimation exploits the computational efficiency of conditional regression models. Applications are demonstrated through three case studies that illustrate flexibility and wide applicability of the design: 1) analysis of associations between air pollution and asthma recurrence using a general practitioners patients cohort; 2) country-wide study of temperature-mortality associations using small-area data and high-resolution exposure maps; 3) analysis of effects of weather on musculoskeletal pain in a cohort of patients, with daily questionnaires and geo-located exposures collected through a smartphone app. The case time series design combines several advantages, such as an individual-level setting, strict confounding control, modelling flexibility, and computational efficiency. Its longitudinal structure allows investigation of complex temporal dependencies and the definition of individual risk profiles, making full use of new big data resources for environmental studies.

## **O01.04.16. Expose: An R Package for Estimating Individual and Average Joint Effects of Chemical Mixtures, Dose-Response Relationships, and Potential Interactions in Environmental Epidemiology**

Ibon Tamayo

*Ibon Tamayo<sup>1</sup>, Youssef Oulhote<sup>2</sup>, Marie-Abele Bind<sup>1</sup>*

*1. Department of Statistics, Harvard University, Cambridge, MA, United States.*

*2. Department of Environmental Health, Harvard T. H. Chan School of Public Health, Boston, MA, United States.*

**Abstract:** Introduction: Although the general population is exposed to multiple chemicals, most environmental epidemiology studies consider each chemical separately when estimating the adverse effects of environmental exposures, partly because of the lack of software accessible to environmental epidemiologists. Objective: We developed a statistical R package, accessible to environmental health scientists that can provide valid estimates for effects of environmental contaminants, dose-response relationships, and interactions in a multi-pollutant setting. Methods: This package implements the work of Oulhote et al (2017) that combines the G-formula, a maximum likelihood estimator, with the ensemble learning technique Super Learner. It incorporates a wide range of statistical techniques (e.g. generalized linear and additive models, random forest, extreme gradient boosting) to estimate and provide valid inference in multi-pollutant settings and reconstruct dose-response relationships non-parametrically. Results: This package will facilitate multi-pollutant analysis of environmental epidemiology. We also developed a user-friendly Shiny application that can be used by biomedical researchers modeling complex mixtures. We ran multiple simulations based on real scenarios and the proposed method yielded promising results across all the scenarios. Our approach was also able to estimate the true underlying structure of the data. We will present a tutorial describing the package functions and visualizations to illustrate our developed methods. Conclusion: This package will help to unravel the effects of chemical mixtures and their interactions in epidemiological studies. Youssef Oulhote, Marie-Abele Bind, Brent Coull, Chirag, Patel, Philippe Grandjean. 2017. Combining Ensemble Learning Techniques and G-Computation to Investigate Chemical Mixtures in Environmental Epidemiology Studies. ## **O01.04.17. Influence of the Urban Exposome on Birth Weight**

Mark Nieuwenhuijsen

*Mark Nieuwenhuijsen<sup>1</sup>, Lydiane Agier<sup>2</sup>, Martine Vrijheid<sup>1</sup>, Remy Slama<sup>2</sup>, on behalf of the Helix Team<sup>1</sup>*

*1. ISGlobal, Barcelona, Spain.*

*2. Inserm, Grenoble, France.*

**Abstract:** Background: We aimed to evaluate the association of the urban exposome with birth weight and term low birth weight. Methods: We estimated exposure to the urban exposome, including the built environment, air pollution, noise, meteorology and natural space (corresponding to 75 exposure variables covering 30 exposure groups ) for nearly 32,000 pregnant women from 6 European birth cohorts. We used two different statistical methods to evaluate possible associations with either continuous birth weight or term low birth weight risk: An exposure-by-exposure method accounting for multiple hypotheses testing, the so called exposure wide association studies (ExWAS) and one method Deletions-Substitution-Addition (DSA), algorithm accounting for correlated exposures. Results: The most consistent statistically significant associations across the statistical analyses were for green space estimated as Normalized Difference Vegetation Index (NDVI) with birth weight and term low birth weight (an increase in birth weight with increasing NDVI). Furthermore, we observed statistically significant associations for PM2.5, and built environment exposures such as walkability index, number length of public bus lines, number of facilities, presence of green space, connectivity density, building density, and land use Shannon's Evenness index and (low) birth weight, but mostly in our ExWAS analyses (after p value correction) and in general the results were not statistically significant when several exposures were included in the same model. Conclusion: This is the first large urban exposome study on birth weight testing many environmental urban exposures. It confirmed some previously reported associations e.g. for NDVI. We generated hypotheses for a number of built environment exposures.

## **001.04.18. Early Life Metal Exposures and Neurodevelopmental Trajectory Profiles: Assessment Using Parallel Latent Growth Mixture Models**

Shelley Liu

*Shelley H. Liu<sup>1</sup>, Jack Rowland<sup>1</sup>, Qixuan Chen<sup>2</sup>, Martha M. Téllez-Rojo<sup>3</sup>, Lourdes Schnaas<sup>4</sup>, Maria Luisa Pizano<sup>4</sup>, Chris Gennings<sup>5</sup>, David Bellinger<sup>6</sup>, Robert Wright<sup>5</sup>*

**Abstract:** Introduction: Neurodevelopment delay is an important public health problem, affecting up to 15% of children. We aim to identify environmental risk factors that predict delayed trajectories of neurodevelopment using latent growth mixture modeling (LGMM). Methods: We use the Programming Research in Obesity, Growth, Environment and Social Stress, (PROGRESS) a longitudinal birth cohort in Mexico with repeated measures of Bayley Scales of Infant and Toddler Development (BSID) (n = 520). The BSID subscales for motor, cognition and language are assessed at four time points from 6 months to 24 months of age. Covariates include maternal hemoglobin, maternal IQ, socioeconomic status, maternal education level, child birthweight and child gender. We build parallel process LGMM to identify distinct subgroups (classes) with similar growth trajectories. We simultaneously model all three BSID subscales while adjusting for covariates, and allow for potentially nonlinear trajectories using quadratic growth factors. We then test for the association between blood metal concentrations (arsenic, cadmium, cobalt, chromium, cesium, copper, manganese, lead, antimony, selenium, zinc) collected during pregnancy and latent class membership. Results: We find that a four-class model best fits the data, and each class is characterized by distinct growth trajectories for the three BSID subscales. We interpret the classes as: high normal (4.2%), early normal (52.3%), late normal (35.2%), and early delayed (8.3%). The early delayed group has significantly lower exposures to zinc (p=0.05) at the second trimester of pregnancy, as compared with all other classes. Furthermore, the early delayed group has significantly lower concentrations of manganese (p=0.02), zinc (p=0.004) and copper (p=0.02) in child's blood at birth as compared with all other classes. Conclusions: Latent classes of neurodevelopment may be differentially vulnerable to metal exposures.

## **O01.04.19. A Causal Inference Approach to Understand the Link between Air Pollution Exposure and the Occurrence of Multiple Sclerosis Relapses**

Alice Sommer

*Alice Sommer<sup>1</sup>*

*1. Statistics, Harvard University - Faculty of Arts and Sciences, Cambridge, MA, United States.*

Abstract: When answering environmental health related questions, most often, only non-randomized observational data can be collected for ethical or practical reasons. The lack of randomized exposure prevents the identification of the causal effects on health outcomes. This barrier led the environmental epidemiology field to mainly consider associational models to examine relationships between environmental exposures and health outcomes. However, we believe that epidemiological researches should focus on the estimation of causal effects of plausible hypothetical interventions (e.g., reducing PM10) and suggest preventive environmental actions. Some statistical matching techniques exist to reconstruct plausible randomized experiments, which are the "gold standard" to establish causality. Based on an environmental epidemiology example, we will present, 1) how the conceptual and design stages can be performed prior to statistical estimation of causal effects, and 2) why this conceptual and computational work is relevant for making policy recommendations. A case-cross over study by Jeanjean et al. 2017 reported significant associations between multiple sclerosis (MS) relapse incidence and exposures to NO<sub>2</sub>, PM<sub>10</sub>, and O<sub>3</sub>. With the same data, we will show how constructing hypothetical experiments, thereby creating comparable groups of MS patients can provide results that are relevant for policy makers. Several epidemiological studies have reported significant associations between air pollution and multiple sclerosis (Oikonen et al. 2003, Gregory et al. 2008, Heydarpour et al. 2014, Angelici et al. 2016, Jeanjean et al. 2017), whereas other studies did not find any (Palacios et al. 2017). These conflicted findings demonstrate the gap of knowledge in understanding the causal air pollution-MS relationship. Our objective is to show that carefully avoiding confounding of the exposure assignment prior to any analysis can help to examine whether observed associations are truly causal.

## O01.04E. Prenatal Metals Exposure

### O01.04.20. Prenatal Heavy Metal Exposure and Newborn Leucocyte Telomere Length: A Birth-Cohort Study in Myanmar

Kyi Wai

**Abstract:** Background: Arsenic, cadmium and lead are associated with telomere length (TL) maintenance in adults. Although they are confirmed to have trans-placental circulation, the effect of prenatal exposure of those metals on newborn TL is unknown. Objectives: The aim of this study was to determine whether prenatal heavy metal exposure has an impact on newborn leucocyte TL. Methods: A birth-cohort study was conducted with 409 pregnant women and their newborns in Myanmar. During the first visit, face to face interviews were performed and maternal spot urine samples were collected. Cord blood samples were collected during follow-up. Urinary heavy metal concentration was measured by ICP-MS and adjusted for creatinine. Relative TL was measured by quantitative real-time polymerase chain reaction. The extent of prenatal arsenic, cadmium and lead exposure and their associations with newborn leucocyte TL were assessed using multivariate linear regression. Results: The median values of maternal urinary arsenic, cadmium, and lead concentrations were 73.8, 0.9, and 1.8  $\mu\text{g/g}$  creatinine, respectively. Prenatal arsenic and cadmium exposure was significantly associated with newborn TL shortening (coefficient = - 0.13, 95% CI: - 0.22, - 0.03,  $p = 0.002$ , and coefficient = - 0.17, 95% CI: - 0.27, - 0.07,  $p = 0.001$ , respectively), and the associations remained robust after adjusting for confounders. However, there was no significant association between prenatal lead exposure and newborn TL. Conclusion: The present study identified the effect of arsenic and cadmium exposure on TL shortening, even in utero exposure at a lower concentration.

## **001.04.21. In Utero and Peripubertal Metals Exposure in Relation to Reproductive Hormones and Sexual Maturation in Girls**

Pahriya Ashrap

*Pahriya Ashrap<sup>1</sup>, Deborah Watkins<sup>1</sup>, Brisa Sánchez<sup>2</sup>, Martha M. Téllez-Rojo<sup>3</sup>, Marcela Tamayo y Ortiz<sup>3</sup>, Karen E. Peterson<sup>4</sup>, John Meeker<sup>1</sup>*

**Abstract:** Metals occur naturally in the environment and are potential endocrine disrupting chemicals (EDCs). In utero development and adolescence are critical windows of susceptibility to EDC exposure. Few human studies have evaluated the impact of metal exposure on pubertal development. Our aim was to investigate in utero and peripubertal metal exposure in relation to pubertal development among girls from the Early Life Exposure in Mexico to Environmental Toxicants (ELEMENT) study. We measured urinary concentrations of Ni, Cu, Mo, Sb, Ba, Pb, Fe, As, Se, Al, Mn, Co, Zn, and Cd in maternal samples collected during the third trimester of pregnancy and their female children at 8-13 years (n=114). In girls, we measured serum testosterone, estradiol, dehydroepiandrosterone sulfate (DHEA-S), inhibin B, and sex hormone-binding globulin (SHBG) at age 8-13, and assessed sexual maturation (Tanner staging: breast, pubic hair development; menarche status), at two time points (8-13, 14-20 years). We used linear regression to independently examine in utero and peripubertal metal levels as predictors of peripubertal hormones. In a longitudinal analysis using generalized estimation equations, we evaluated Tanner stage and menarche progression in relation to in utero and peripubertal metal levels. We found that higher in utero Zn was associated with increased inhibin B, while in utero Ni, Al, Mn, and Cd were associated with slower progression of breast development after adjustment for child age and BMI z-score. Several metals at 8-13 years were associated with higher DHEA-S and estrogen, while Ni was positively but Cu was negatively associated with testosterone. Peripubertal levels of some metals were also associated with being at a higher pubic hair Tanner stage and menarche. These findings suggest that female reproductive development may be vulnerable to the effects of metal exposure, and using both Tanner stage and hormone levels provides essential information about underlying mechanisms.

## **001.04.22. Chemical Mixture Exposures during Pregnancy and Birth Outcomes**

Geetika Kalloo

*Geetika Kalloo<sup>1</sup>, Gregory A. Wellenius<sup>1</sup>, Lawrence McCandless<sup>2</sup>, Antonia Calafat<sup>3</sup>, Andreas Sjodin<sup>3</sup>, Margaret R. Karagas<sup>4</sup>, Aimin Chen<sup>5</sup>, Kimberly Yolton<sup>6</sup>, Bruce P. Lanphear<sup>2</sup>, Joseph M. Braun<sup>1</sup>*

Abstract: Exposure to environmental chemical mixtures, which is prevalent among pregnant women, may be associated with altered fetal growth and gestational duration. In a prospective cohort of 380 pregnant women from Cincinnati, OH (enrolled 2003-2006), we quantified biomarker concentrations in urine and blood of 35 organic pollutants, cotinine, and 4 metals. We used K-means clustering and non-negative principal component (PC) analysis to characterize chemical mixtures among pregnant women. Then, we used multivariable linear regression to estimate and compare the covariate-adjusted associations of cluster membership or PC scores with gestational-age-specific birth weight z-score, birth length, head circumference, and gestational duration. Geometric mean biomarker concentrations were generally higher among women in cluster 1, intermediate among women in cluster 2, and lowest among women in cluster 3. Chemical biomarkers in the same structural or commercial family loaded onto the same PC. Compared with children born to women in cluster 3, children born to women in clusters 1 and 2 had 0.28 cm (95% CI: -0.86, 0.30) and 0.13 cm (95% CI: -0.65, 0.38) shorter birth length, respectively. Each standard deviation increase in PC 4 (correlated with organochlorine pesticides, cadmium, and lead) and PC 6 (correlated with mercury and monoethyl phthalate (MEP)) was associated with a 0.24 cm (95% CI: -0.49, 0.02) and 0.14 cm (95% CI: -0.42, 0.14) decrease in birth length, respectively. Chemical biomarkers with higher concentrations among women in clusters 1 and 2 loaded more strongly on both PC 4 and PC 6 than other PCs. Neither cluster membership nor PC scores were associated with birth weight z-score, head circumference, or gestational duration. In this cohort, cluster membership and PC scores reflecting exposure to cadmium, mercury, lead, organochlorine pesticides, and MEP were both inversely associated with birth length, but not other fetal growth measures or gestational duration.

## **001.04.23. The Relationships between Maternal Urinary Trace Metals and Plasma Immune Biomarkers during Pregnancy**

Tun (Max) Aung

*Tun (Max) M. Aung<sup>2</sup>, John Meeker<sup>1</sup>, Jonathan Boss<sup>3</sup>, Kelly Bakulski<sup>4</sup>, Bhramar Mukherjee<sup>3</sup>, David Cantonwine<sup>6</sup>, Thomas McElrath<sup>6</sup>, Kelly Ferguson<sup>5</sup>*

**Abstract:** Background: Environmental exposure to metals is widespread and may pose a risk for adverse birth outcomes. Metals may impact these outcomes through immunotoxic mechanisms via perturbations in maternal immune signaling molecules. We aimed to characterize associations between maternal urinary trace metals and plasma C-reactive protein (CRP) and cytokines in pregnancy. Methods: We conducted a cross-sectional study of pregnant women recruited early in pregnancy (<15 weeks gestation) from the LIFECODES birth cohort, which included 99 cases of preterm birth and 291 unmatched randomly selected controls. Through collaboration with the Children's Health Exposure Analysis Resource, we measured 17 urinary metals and five plasma immune biomarkers from samples collected in the 3rd trimester (median 26 weeks gestation). We used linear regression to calculate associations between metals and immune biomarkers, using inverse probability weights to account for case status, and adjusting for specific gravity, maternal age, race, and body mass index at the initial study visit. We used the elastic net to perform variable selection to assess relationships between multiple metals and immune biomarkers. Results: Single pollutant linear regression models revealed that several metals were associated with pro-inflammatory markers. An interquartile range (IQR) difference in Selenium (39 µg/L) was associated with a 65% increase in CRP (95% Confidence Interval (CI): 22.3 - 123). The elastic net revealed that Barium (Ba), Manganese (Mn), and Nickel (Ni) were positively associated with interleukin-1β (IL-1β), with Mn having the largest effect estimate. An IQR difference in Mn (0.6 µg/L) was associated with a 29% increase in IL-1β (95% CI: 12.4 - 48.2). Conclusions: Our results indicate that higher concentrations of Se, Mn, Ba, and Ni are related to higher pro-inflammatory immune biomarkers in pregnancy. Systemic immune perturbations may increase the risk of adverse birth outcomes.

#### **001.04.24. Bone Remodeling and Metals Exposure during Pregnancy: Results from Progress Cohort**

**Abstract:** Background: Environmental exposure to metals has been associated with decreased bone density and higher risk of fracture mainly among premenopausal women and older adults. Metals such as lead (Pb) and cadmium (Cd) interfere with calcium incorporation into the bone cells leading to low bone density. However, little is known about the effects of metals exposure on bone remodeling during pregnancy, a window of susceptibility to the toxic effects of metals. Objective: The aim of this study was to assess concurrent exposure to metals [Pb, Cd, chromium (Cr) and arsenic (As)] and bone remodeling at radius during second and third trimester of pregnancy. Methods: We studied 1,054 mothers from PROGRESS cohort (Programming Research in Obesity, Growth, Environment and Social Stress). We measured BMD at radius by ultrasound and metals exposure by inductively coupled plasma during second and third trimesters of pregnancy. We generated linear mixed models to assess associations between metals exposure and z-scores at radius during second and third trimesters of pregnancy. Additionally, at each trimester of pregnancy, we assessed associations between metals exposures and z-scores using simple linear regression models. Results: At third trimester of pregnancy, Pb and Cr were associated with lower z-score at radius [for Pb (estimate: -0.89; 95% CI: -1.54, -0.24) and for Cr (estimate:-0.70; 95% CI: -1.37, -0.34)] in adjusted models. Similarly, we observed a decreasing trend in z-score at radius associated with Pb and Cr exposure during pregnancy, although it was not statistically significant. Overall, we did not observe associations between Cd or As and z-scores during pregnancy. Conclusions: Lead and chromium exposure during the third trimester of pregnancy might decrease bone remodeling at radius. Further studies should be conducted to assess bone remodeling at different anatomic sites in relation to metals exposure during pregnancy.

## Neurological and Cognitive Outcomes Associated with Air Pollution

### O01.04.25. Genetic Variation in Biotransformation Enzymes, Air Pollution Exposures, and Risk of Spina Bifida

Amy Padula

*5. University of California Berkeley, Berkeley, CA, United States.*

Abstract: Spina bifida is a birth defect characterized by incomplete closure of the embryonic neural tube. Genetic factors as well as environmental factors have been observed to influence risks for spina bifida. Few studies have investigated possible gene-environment interactions that could contribute to spina bifida risk. The aim of this study is to examine the interaction between gene variants in biotransformation enzyme pathways and ambient air pollution exposures and risk of spina bifida. We evaluated the role of air pollution exposure during pregnancy and gene variants of biotransformation enzymes from bloodspots and buccal cells in a California population-based case-control (86 cases of spina bifida and 208 nonmalformed controls) study. We considered race/ethnicity and folic acid vitamin use as potential effect modifiers and adjusted for those factors and smoking. We observed gene-environment interactions between each of the five pollutants and several gene variants: NO (ABCC2), NO<sub>2</sub> (ABCC2, SLC01B1), PM<sub>10</sub> (ABCC2, CYP1A1, CYP2B6, CYP2C19, CYP2D6, NAT2, SLC01B1, SLC01B3), PM<sub>2.5</sub> (CYP1A1 and CYP1A2). These analyses show positive interactions between air pollution exposure during early pregnancy and gene variants associated with metabolizing enzymes. These exploratory results suggest that some individuals based on their genetic background may be more susceptible to the adverse effects of pollution.

#### **O01.04.26. Fine Particulate Matter Air Pollution and Incidence of Cognitive Impairment among the Elderly in China**

Jiaonan Wang

*Jiaonan Wang<sup>1</sup>, Yi Zhang<sup>1</sup>, Yuebin Lv<sup>1</sup>, Tiantian Li<sup>1</sup>, Xiaoming Shi<sup>1</sup>*

*1. Institute for Environmental Health and Related Product Safety, Chinese Center for Disease Control and Prevention, Beijing, China.*

**Abstract:** Background/Aim: Long-term exposure to fine particulate matter (PM2.5) has been shown to increase risk of cognitive impairment. However, research on the relationship between exposure to PM2.5 and cognitive function is lacking in developing countries, especially in highly polluted areas. The aim of this study is to determine if exposure to PM2.5 is associated with cognitive function in a diverse, national sample of older adults in China. Methods: This analysis included data on 5704 older adults aged  $\geq 65$  years from the Chinese Longitudinal Healthy Longevity Survey (CLHLS) in 2008-2011, which randomly selects half of the counties and cities in 23 of China's 31 provinces. We used geographic information system to estimate annual average satellite-derived PM2.5 concentration for the geocoded location of participants' baseline residences enrolled between 2008 and 2011. The cognitive function was assessed with Mini Mental State Evaluation (MMSE) scale. Association between PM2.5 concentration and cognitive impairment was analyzed by logistic regression model. Results: The average age of participants was 79.6 years. Logistic regression analysis results showed that a  $10\mu\text{g}/\text{m}^3$  increase in PM2.5 concentration was associated with an increased odds of incident impairment, after adjusting for demographic factors and behavioral factors [RR (95% CI): 1.06 (1.01, 1.11)]. The effect is especially significant in men, current alcohol drinker, current smoker, the elder age group and hypertensive patients. Conclusions: PM2.5 was associated with increased risk of cognitive impairment incidence in the elderly of China. Air pollution reduction is a potential measure for reducing the future population burden of age-related cognitive decline, especially in heavy air polluted area.

## S01.04A. Addressing Complexities through Partnership and Collaboration in the Arctic

### **S01.04.01. Exposure to Perfluoroalkyl Substances and Polybrominated Diphenyl Ethers from Traditionally Harvested Food Animals on St. Lawrence Island, Alaska**

Sam Byrne

*Sam Byrne<sup>1</sup>, Thoin Begum<sup>1</sup>, Pamela Miller<sup>2</sup>, Samarys Seguinot-Medina<sup>2</sup>, Vi Waghiyi<sup>2</sup>, C. Loren Buck<sup>3</sup>, Frank A. von Hippel<sup>3</sup>, David O. Carpenter<sup>4</sup>*

- 4. Univeristy at Albany, Rensselaer, NY, United States.*

**Abstract:** The Arctic serves as a hemispheric sink for persistent organic pollutants (POPs). Indigenous arctic populations are exposed to POPs through traditional harvest of food animals, including marine mammals. This study quantified 13 perfluoroalkyl substances (PFAS) and 40 polybrominated diphenyl ethers in traditional food animals harvested by residents of St. Lawrence Island, Alaska. Of 13 measured PFAS, 9 were detectable in any sample. Overall PFAS concentrations were highest in seal tissue. In seal tissue samples, Perfluoropentanoic acid (PFPeA) was the most commonly detected PFAS, and was present at the highest mean concentration of any PFAS (15.4 ng/g ww). PFPeA was also the most commonly detected PFAS and was present the highest maximum concentration (24.8 ng/g in seal muscle). Analysis of heart, liver, kidney and intestine samples from a single juvenile seal suggest that PFAS may preferentially partition into organs. Both total concentrations of PFAS and the number of detectable compounds were higher in these organ meats. Polybrominated diphenyl ethers (PBDEs) were detected in 100% of traditional foods samples. BDE-47, 99, 100 and 209 tended to make up a large percentage of overall PBDE concentrations. Seals had the highest median concentrations compared to other species. BDE-47 made up the majority of overall PBDE concentrations in seal samples. The median total PBDE concentration in seal blubber from this study (2,511 pg/g ww) was lower than the concentration reported in harbor seals collected in Alaska in 2000-2002 (14,600 pg/g ww). This is consistent with the overall decreasing trends of PBDEs in the Arctic.

## **S01.04.02. Overview of Human Health Risk Assessments**

Zoe Gillespie

*Zoe Gillespie<sup>1</sup>*

*1. Food Directorate, Health Canada, Ottawa, ON, Canada.*

Abstract: A general overview of the role of Health Canada's Food Directorate within the Northern Contaminants Program and how country food contaminant data is assessed in order to provide a health risk opinion. This overview will include a hypothetical case study to illustrate the various factors and the uncertainties that are considered with an assessment and highlight additional factors that are taken into consideration when determining whether consumption advisory is warranted.

### **S01.04.03. Discovering Chemicals of Emerging Arctic Concern: Application of New Analytical Approaches to Human Biomonitoring**

Pierre Ayotte

*Pierre Ayotte<sup>1</sup>, Pierre Dumas<sup>2</sup>*

*1. Université Laval, Quebec, QC, Canada.*

*2. Centre de toxicologie, Institut national de santé publique du Québec, Quebec, QC, Canada.*

Abstract: Different analytical strategies are used to discover chemicals of emerging concern in the Arctic. While traditional targeted analyses allow for the identification and quantification of chemicals with a priori knowledge of their presence, semi-targeted and untargeted analyses also permit samples obtained in the framework of human biomonitoring studies to be screened for the presence of unknown or unsuspected pollutants. We recently applied these different analytical strategies to human biomonitoring studies conducted in various regions of the Arctic. Chemical families targeted in plasma samples include polychlorinated biphenyls and chlorinated pesticides, polychlorinated dibenzo-p-dioxins and dibenzofurans as well as perfluorinated compounds. Targeted interrogation of the non polar purified extracts revealed the presence of chlorobenzenes, polycyclic aromatic hydrocarbons, polychlorinated naphthalenes, polychlorinated terphenylenes, short-chain chlorinated paraffins and natural halogenated compounds. Through untargeted analyses of extracts, thousands of entities are detected. Chemometric methods such as Kendrick mass defect plot and isotopic pattern detection can be used to attribute unknowns to the proper chemical family and facilitate compound identification. These innovative strategies will help identifying chemicals of emerging Arctic concern that should be included in future biomonitoring studies and considered for inclusion under the Stockholm Convention.

#### **S01.04.04. Human Health in the Arctic: The Arctic Monitoring and Assessment Programme**

Jon Oyvind Odland

*Jon Oyvind Odland<sup>1</sup>*

*1. ISM, NTNU Trondheim Norway, Bodø, Norway.*

Abstract: The Arctic Monitoring and Assessment Programme (AMAP) has a history back to 1991. The Human Health Assessment Group (HHAG) was established in 1993. The first report was submitted in 1998, followed by comprehensive reports in 2003, 2009, and 2015. The generous contribution from the Canadian partners in the first phase resulted in a historical monitoring program with samples from all Arctic countries analysed at CTQ in Quebec, with strict routines of sampling, storage, transportation, and finally analyses of toxic and essential metals, as well as persistent toxic substances (PTS) in blood samples from all participating countries. The first report was mostly a monitoring of levels in human samples, while the following reports built on the mother-child cohorts connected to the monitoring, with continuous new knowledge of human health effects in the complicated field of child development, nutrition, life style, and exposure to the toxic elements. The cohorts are ongoing, and the communication of results is steadily developed in close collaboration with health authorities. This presentation will present the broad picture, but also discuss recent important findings, effects in different geographical areas, and give future perspectives for public health impact from contaminants, nutrition, and life style. The development and sustainability of the partnership in the group is crucial for future work on both monitoring and effect studies. The group has also added new knowledge to global environmental science, with specific strategies for cohort studies in scarcely populated regions.

## S01.04B. Aggregate Exposure and Cumulative Risk Assessments in the Euromix Project

### S01.04.06. Identification of Key Mixtures in European Countries and Assessment of Consequential Exposures

Amélie Crépet

*Amélie Crépet<sup>1</sup>, Marie Vanacker<sup>1</sup>, Corinne Sprong<sup>2</sup>, Waldo de Boer<sup>3</sup>, Hilko van der Voet<sup>3</sup>, Jacob V. Klaveren<sup>2</sup>, WP5 Euromix participants<sup>4</sup>*

- 2. National Institute for Public Health and the Environment, Bilthoven, Netherlands.*
- 3. Biometris, Wageningen University & Research, Wageningen, Netherlands.*
- 4. Euromix project, Europe, France.*

Abstract: Through their diet, populations are exposed to mixtures of chemicals which can cause health diseases. Due to the complexity of mixtures, the question of which substances should be assessed together remains a big challenge. The EuroMix project developed a strategy for mixture risk assessment and proposed an original method combining exposure and hazard information to identify the key mixtures of chemicals to which populations are exposed. The principle is to reduce the number of substances in a defined cumulative assessment group (CAG) identifying co-occurring substances in diet. The method is based on sparse non-negative matrix under approximation to factorize the co-exposure matrix into two non-negative matrices. The method is illustrated on the liver steatosis CAG using children and adults exposure in 9 European countries. Food consumption and pesticide residue in food and drinking water came from national surveys. Exposures of 144 pesticides were evaluated through scenarios related to chronic/acute exposure and merged/country specific residue data. Relative potency factors were calculated to express the potency of each substance relative to the flusilazole and multiplied by the exposure. Considering chronic exposure, one mixture explained the major part of the total variance for each country, while in acute exposure, several mixtures were often needed to explain the major part of the total variance. The results showed that 15 pesticides were mainly observed in mixtures, with a high contribution of imazalil and dithiocarbamates. The originality of the proposed approach was to start from a CAG and to integrate information from co-exposures to identify key mixtures with much fewer components. As this approach was sensitive to the input data heterogeneity, efforts should continue on data collection and harmonization among the different aspects within the regulatory framework.

#### **S01.04.07. Verification of Aggregated Exposure to Bisphenols from Diet and Cosmetics - The Human Biomonitoring Study from the EU Project Euromix**

Monica Andreassen

*Monica Andreassen<sup>1</sup>, Cecile Karrer<sup>2</sup>, Natalie von Goetz<sup>3</sup>, Amrit Sakhi<sup>4</sup>, Hubert Dirven<sup>1</sup>, Trine Husøy<sup>1</sup>*

*4. Environmental Exposure and Epidemiology, NIPH, Oslo, Norway.*

Abstract: Bisphenols have many applications in consumer products, and exposure occurs from a vast number of sources and via several routes. In order to examine the plausibility of source-to-dose calculations of aggregate exposure of bisphenols in the EuroMix project, a biomonitoring study was performed. For two 24-hour study periods separated by 2-3 weeks, adult volunteers (n=144) in Norway kept detailed diaries on food consumption (type/brand of foods, weight, time point and packaging material) and the usage of PCPs (type/brand of product, time and number of applications, and number of showers and hand washes). Concurrently, 24h urine was collected and urinary levels of the bisphenols BPA, BPS, BPF, and BPAF were analyzed using on-line column switching ultra high performance liquid chromatography and tandem mass spectrometry (UPLC-MS-MS). The exposure models MCRA and PACEM were used to estimate dietary and non-dietary exposure of the bisphenols in line with the information obtained from the study. Bisphenol concentrations in food and PCPs were taken from literature. Internal exposures were obtained with a previously published PBPK model. Estimates of voided urine concentrations obtained with the models were then compared with measured urine concentrations to evaluate the coupling of aggregate exposure models, which was developed within the EuroMix framework.

#### **S01.04.08. Aggregate and Cumulative Exposure to Pyrethroids of French Population**

Marie Vanacker

*Marie Vanacker<sup>1</sup>, Paul Quindroit<sup>2</sup>, Celine Brochot<sup>2</sup>, Amélie Crépet<sup>1</sup>*

*1. Departement of Risk Assessment, ANSES, French Agency for Food, Environmental and Occupational Health and Safety, Maisons-Afort, France.*

*2. INERIS, Verneuil-en-Halatte, France.*

Abstract: Pyrethroids are commonly used as insecticides and can be found in both outdoor and indoor environments. More specifically, these substances could be found in food, in air, in dust, in cosmetics and in veterinary products. The ENNS study (2005-2006) showed that the pyrethroid metabolite body burden of the French adult population is much greater than German and North-American ones. In response to this observation, aggregate and cumulative external exposures of the French adult population to four major pyrethroids (cyfluthrin, cypermethrin, deltamethrin and permethrin) were evaluated, taking into account exposure by ingestion, inhalation and dermal contact. In total seven routes of dietary and non-dietary exposures were combined (food ingestion, dust ingestion, dust dermal contact, air inhalation, dermal contact by animals and by cosmetics). For left censored data, two scenarios using lower (LB) and upper bounds (UB) were compared. Exposure sources contributing the most to aggregate exposure were then identified for each substance and censor scenario. The cumulative risk assessment associated to the neurotoxicity effect was also evaluated using relative potency factors based on deltamethrin, as the substance of reference. First results showed that the sources of exposures and the contribution of substances mainly differed between the different censor scenarios. The dietary exposures of deltamethrin and cypermethrin, and the dermal contact exposure of permethrin through animal handling, were the main contributors of the cumulative exposure for the LB scenario, while the dietary exposure of cyfluthrin and the deltamethrin contributed the most for the UB scenario. These results confirm high values of metabolites in the French adult population. After integrating the external exposure in a PBPK model, the resulting metabolite body burden will be compared to those observed in the ENNS study.

#### **S01.04.09. Aggregate Exposure and Cumulative Risk Assessment of the Bisphenols BPA, BPS, BPF, and BPAF for the French Population**

Cecile Karrer

Abstract: Bisphenol A (BPA) is used in the production of polycarbonate plastics and epoxy resins and for the color development in thermal paper (TP). In the EU, since 2011 its use in plastic materials and articles intended to come into contact with food is subject to a migration limit. In view of the increasingly strict legislation, industry has partly turned towards replacement chemicals for BPA, such as bisphenol S (BPS), bisphenol F (BPF), and bisphenol AF (BPAF). These analogues can e.g. be found in foodstuffs, indoor dust, and thermal paper. Several studies showed that they exert estrogenic effects just like BPA. To evaluate whether the European BPA restrictions had effects on exposures to BPA and its analogues, we conducted comparative exposure and risk assessments for the time before and after the year 2011. We modeled exposures for European consumers and further focused on the French population. We regarded all sources, which significantly contributed to exposure in previous assessments: dietary and dust ingestion, and dermal exposure from personal care products (PCPs) and TP. Wherever possible, we used concentration data from before and after 2011, respectively. We used the Monte Carlo Risk Assessment (MCRA) model for dietary exposure, the Probabilistic Aggregate Consumer Exposure Model (PACEM) for exposure to PCPs and other probabilistic models for TP and dust. We aggregated the realistic external exposures from different sources by means of a physiologically based pharmacokinetic (PBPK) model developed previously for these bisphenol analogues, yielding internal exposures. We used relative potency factors to estimate the cumulative risk that could result from combined internal exposure to BPA, BPS, BPF, and BPAF. For this, we compared the margins between effective concentrations and the cumulative internal exposures for the time before and after 2011.

## **S01.04.10. Taking Account of Variability and Uncertainty in Cumulative Risk Assessment**

Waldo de Boer

*Waldo de Boer<sup>1</sup>, Hilko van der Voet<sup>1</sup>, Johannes Kruisselbrink<sup>1</sup>, Marco van Lenthe<sup>1</sup>*

*1. Biometris, Wageningen University & Research, Wageningen, Gelderland, Netherlands.*

Abstract: Human populations are exposed to many chemicals that may cause the same health effect. In a risk assessment, exposures coming from dietary and non-dietary routes (e.g. oral, dermal and inhalation) are aggregated and combined with hazard data. The aim is to characterise the health impact due to the combined effect of multiple chemicals. In a refined approach, kinetic models translate the external dose coming from various routes to the internal dose at the level of the target organ, e.g. the liver. The models are substance-specific, so accumulation over multiple substances can only be performed at the internal dose level. Humans may be exposed to hundreds or thousands of chemicals that may cause the same health effect, facing kinetic modellers with a seemingly impossible task. So there is a need for model simplification or simple approaches like using absorption factors to obtain generalised models for classes of substances. The EuroMix toolbox is a user-friendly, web-based platform that implements models for exposure and risk assessment. Both exposure assessment through the use of kinetic models and hazard characterization are included in a probabilistic way. Uncertainties involved enter the model by using a two dimensional Monte Carlo approach. This results in an uncertainty distribution for any statistic of interest, e.g. the margin of exposure.

## S01.04C. Assessing Health and Well-Being Benefits of Exposure to Natural Environments: Methodological Challenges and Opportunities

### S01.04.11. Urban Green Spaces and Health - Evidence, Limitations, and Ways Forward

Matilda van den Bosch

*2. Swedish University of Agricultural Sciences, Alnarp, Sweden.*

**Abstract:** Based on scientific evidence, the World Health Organization advocates for public green space as an important component of healthy cities. Different pathways and mechanisms are likely to mediate the health effects of exposure to green spaces. Those range from stress reduction and increased physical activity to regulating ecosystem services, such as heat and noise reduction. Many of these pathways are causally related to common non-communicable diseases, for example, depression, and urban heat related morbidity, disorders that have been negatively associated with exposure to green spaces. The evidence is limited by various factors, such as lack of validation of exposure metrics and shortness of experimental data. Attempts to standardise and optimise exposure metrics are ongoing, but depending on what health outcome is studied different types of measurements are needed. For example, measuring the impact on heat related morbidity may require different metrics than for estimating mental health benefits. Aspects of green space exposure to be considered for measurement are availability, accessibility, qualities, and usage. Availability and accessibility can be determined for large-scale population studies and are often assessed through remote sensing data of various spatial resolution, sometimes combined with other data sources for mapping of land cover types, such as different tree species, of land use, such as recreational areas and sport facilities. Evaluating qualities of green spaces often requires field studies or qualitative analyses, resulting in smaller scale studies. Usage of natural spaces can be identified by big data collection, from sources such as accelerometers or smart phone applications. This presentation will provide an overview of the evidence on associations between urban green spaces and health, based on a systematic review of the literature. It will critically discuss existing exposure metrics and potential for validation and development.

## **S01.04.12. Does Physical Activity Mediate the Effect of Residential Greenness on Mental Health and Subjective Well-Being? Findings from the Sister Study**

Raquel Silva

*Raquel A. Silva<sup>1</sup>, Paul Villeneuve<sup>3</sup>, Wei-Lun Tsai<sup>1</sup>, Steven Prince<sup>2</sup>, Aimee D'Aloisio<sup>4</sup>, Maliha Nash<sup>2</sup>, Megan Mehaffey<sup>2</sup>, Anne C. Neale<sup>2</sup>, Dale Sandler<sup>5</sup>, Timothy J. Buckley<sup>2</sup>*

**Abstract:** Although a growing body of research shows that exposure to natural environments benefits physical and mental health and well-being, there remain significant gaps in our understanding of the factors that influence the association between exposure and health and well-being outcomes. Addressing these gaps, we present results from two projects using health data from NIEHS' Sister Study and residential greenness derived from the US National Land Cover Database. The Sister Study collects various measures from over 50,000 women aged 35-74 years across the United States. The cohort covers broad geographic distribution and demographics that help us understand the potential mechanisms between exposures to nature and health outcomes. Previous cross-sectional analyses of the Sister Study by Villeneuve and colleagues found reduced risks of obesity (body mass index  $\geq 30$ ) for women who lived in areas with the highest tertile of greenness within a 500m residential buffer (odds ratio (OR) = 0.83, 95% CI = 0.79-0.87) relative to those in the lowest tertile. Further, mediation analyses showed that physical activity attenuated the association between greenness and obesity by 32%. In this presentation, we analyze the associations between residential greenness within 250m, 500m, and 1250m buffers, and self-reported health, perceived stress, depressive symptoms and quality of life, controlling for sociodemographic factors, lifestyle, and environmental stressors. Then, we discuss how levels of physical activity mediate the association between mental health and residential greenness. Additionally, we extend previous analyses that investigated the association between overall physical activity and nearby greenness to examine associations with specific types of recreational physical activities, particularly those more likely influenced by proximal greenness. Finally, we discuss the impact of using different metrics for exposure assessment and propose future directions for this research.

### **S01.04.13. High-Resolution Measures of Natural Environments and Mental Health Outcomes in the Nurses' Health Studies**

**Abstract:** The biophilia hypothesis and psychoevolutionary theory suggest that exposure to nature might be linked to better mental health outcomes. Recent studies have observed associations between exposure to nature and mental health; however, many of these studies have used coarse vegetation indices to assess exposure to nature. In addition, as far as the authors are aware, no prior study has examined the relationship between nature and positive psychological constructs, such as optimism. Using high-resolution, aerial photography-based data on natural environments from EPA EnviroAtlas datasets across 18 urban areas, we examined the relationship between residential exposure to natural environments (including green space, tree cover, and proximity to parks) and validated self-reported measures of doctor-diagnosed depression, depressive symptoms, doctor-diagnosed anxiety, social integration, and optimism in over 12,000 female participants in the Nurses' Health Study and Nurses' Health Study II cohorts located in communities across the entire United States. Analyses were adjusted for age, race educational attainment of each participant and her husband, smoking, alcohol consumption, alterative healthy eating index, BMI, and census-tract median family income, home value, and population density. We tested effect modification by individual and area-level socioeconomic status (SES), race, physical activity, population density, and region. Using extremely high-resolution data on natural environments, this study will build the evidence base for nearby nature as a potential environmental intervention to improve psychological well-being. Municipalities have engaged in tree planting and other landscape interventions as part of climate change mitigation and adaptation efforts, and this study provides vital data on nature as a co-benefit for mental health.

#### **S01.04.14. Living Close to Water Is Associated with Reduced Risks of Mortality in Canada's Largest Cities: Results from the Canadian Census Health and Environment Cohort**

Dan Crouse

*Dan L. Crouse<sup>1</sup>*

*1. Sociology, University of New Brunswick, Fredericton, NB, Canada.*

Abstract: Increasing evidence suggests that residential exposures to natural environments, such as green space, are associated with many health benefits. Only a single study has examined the potential link between living near water and mortality. Here, we examine whether living near large, natural water features (e.g., lakes, rivers, coasts, "blue space") is associated with decreased risk of dying from cause-specific mortality among urban, Canadian adults, controlling for many individual and contextual covariates, along with exposures to ambient air pollution and residential greenness. Specifically, we examined whether living within 250 m of blue space was associated with cause-specific mortality among adults living in the 30 largest Canadian cities drawn from the 2001 Canadian Census Health and Environment Cohort. Our cohort included ~1.3 million subjects at baseline, 106,180 of whom died from non-accidental causes during the 11 years of follow-up. We found significant, reduced risks of mortality in the range of 12-17% associated with living within 250 m of water compared to living further away, among all causes of death examined, except with external/accidental causes. For example, in fully-adjusted models, the hazard ratio for non-accidental deaths was 0.879; 95% confidence intervals: 0.861-0.897. Effects were more protective among women and older adults, and most protective for deaths from stroke and respiratory-related causes. Our findings suggest that everyday residential exposures associated with living near blue space in urban areas have important benefits to health, which may be different from those achieved through purposeful visits to natural areas, such as parks or beaches. The findings here suggest that exposures to blue spaces in particular may have much stronger benefits to health than previously suggested.

S01.04D. Biomonitoring Data from the Canadian Health Measures Survey in Risk Assessment: A Decade of Progress

**S01.04.16. Making Biomonitoring and Exposure Knowledge More Accessible for Risk Assessment**

Annie St-Amand

*Andy Nong<sup>1</sup>, Annie St-Amand<sup>1</sup>, Kristin Macey<sup>1</sup>, Devika Poddalgoda<sup>1</sup>, Michelle Deveau<sup>1</sup>, Kim Irwin<sup>1</sup>, Mark Feeley<sup>1</sup>, Lesa Aylward<sup>2</sup>, Sean Hays<sup>3</sup>*

- 2. Summit Toxicology LLP, Falls Church, VA, United States.*
- 3. Summit Toxicology LLP, Bozeman, MT, United States.*

Abstract: Health Canada has invested over the decade at research for the interpretation of Canadian Health Measures Surveys (CHMS) with Biomonitoring Equivalents. The continued collaboration with scientists and regulators from various branches has matured from feasibility research studies into a priority and screening tool that is scientifically sound for chemical assessment at Health Canada. The presentation highlights the success of exposure sciences research implemented into policy for regulatory purpose. After being supported by Chemical Management Plan Monitoring and Surveillance, Biomonitoring Equivalent (BE) research has provided a simple way to understand the health risks from levels measured in biomonitoring surveys. A BE is a screening tool that translates guidance exposure values into an internal metrics or biomarker levels which can be compared to results of biomonitoring surveys. Initially, the study investigated the feasibility of BEs for the interpretation of Canadian Health Measures Survey. The work then continued with BE method development for Health Canada chemical evaluations, capacity building and knowledge transfer. Now, BE are currently being used for screening of biomonitoring data for Chemical Management Plan chemicals at Health Canada. With several publications and policy documents, BEs are helping to identify substances that are of low concern to human health at current levels of exposure under the Chemical Management Plan. The continued collaboration with scientists and regulators from various branches has enabled this research to mature into a robust tool that is scientifically sound for chemical risk assessment and management.

#### **S01.04.17. Using Biomonitoring Data from the Canadian Health Measures Survey and Biomonitoring Equivalents to Assess Risk Associated with Essential Nutrients**

Kristin Macey

*Kristin Macey*<sup>1</sup>

*1. Health Canada, Ottawa, ON, Canada.*

Abstract: Health Canada conducts human health risk assessments for priority substances under the Chemicals Management Plan. Many of these are essential nutrients for human health, including selenium, molybdenum, iodine and zinc. However, elevated exposures can result in adverse health effects. Although the diet is the primary route of exposure to these nutrients, they are ubiquitous in environmental media and as such, there is also potential for exposure from air, water, soil, and house dust. In addition, these substances are present in thousands of products available to consumers; which contributes to overall exposure. With the availability of human biomonitoring data from the Canadian Health Measures Survey (CHMS), Health Canada was able to evaluate integrated exposure from all sources, as biomonitoring data can be used as a measure of internal exposure regardless of the source. General population biomonitoring data from the CHMS, coupled with biomonitoring equivalents (BEs), i.e., the blood or urine equivalent of an exposure guideline such as a tolerable daily intake or reference dose, provided evidence of safety for the general population for selenium, molybdenum, iodine and zinc. Comparison of the CHMS biomonitoring data with data from smaller target studies revealed subpopulations in Canada with elevated exposure and the potential for adverse health effects. Using the same approach, biomonitoring data coupled with BEs for nutritional adequacy (e.g., the estimated average requirement) can also be used to evaluate the nutritional status of Canadians. On average, Canadians meet dietary recommendations for these nutrients, although some deficiencies have been observed across the population.

#### **S01.04.18. Fluoride Levels in Urine and Tap Water in Canada: Data from the Canadian Health Measures Survey 2012-2015 and Interpretation in a Risk-Based Context**

Lesla Aylward

*Kathy Nguyen<sup>1</sup>, Patrick Hamel<sup>1</sup>, Morie Malowany<sup>1</sup>, Anne Vezina<sup>1</sup>, Lesla Aylward<sup>2</sup>, Sean Hays<sup>2</sup>, Mike Walker<sup>1</sup>, Annie St-Amand<sup>1</sup>*

- 2. Summit Toxicology, Lyons, CO, United States.*

**Abstract:** Fluoride is recognized as beneficial to dental health because of its ability to prevent tooth decay. However, excessive fluoride intake may cause dental fluorosis, and at much higher levels skeletal fluorosis and other adverse health effects. For many years, water fluoridation has been introduced in various Canadian communities and around the world as a public health measure to prevent dental decay. Besides tap water, Canadians are exposed to fluoride through food, beverages, and fluoridated dental products. In order to track fluoride exposure in Canada, fluoride levels in urine and tap water of Canadians have been monitored in the Canadian Health Measures Survey (CHMS) in 2012-2015. Using CHMS data and municipal fluoridation information, this study examined fluoride levels in urine and tap water of the Canadian population and potential associations between urinary fluoride levels and various exposure factors. It also aimed at interpreting the urinary fluoride levels in a risk-based context using biomonitoring equivalent (BE) values. Analysis showed that urinary fluoride levels varied by age and sex. Children aged 3-5 years had the highest urinary fluoride levels while the 11-19-year-old had the lowest concentrations. Females had higher urinary fluoride levels than males. The vast majority of Canadians had tap water fluoride levels lower than Health Canada's maximum acceptable concentration. The results also showed that the majority of the population had urinary fluoride levels below the BE values, suggesting that exposure levels in Canadians are generally below the recommended adequate intake levels for fluoride for the prevention of dental caries. This study presents the first nationally representative dataset on fluoride, which will be helpful to inform future risk assessment and management of this chemical in Canada.

#### **S01.04.19. Interpretation of Urinary Concentrations of Pyrethroid Metabolites in the Canadian Population in a Risk Context: Associated Factors and Comparison to Biomonitoring Equivalents**

Kim Irwin

*Subramanian Karthikeyan<sup>1</sup>, Djordje Vladislavljovic<sup>1</sup>, Annie St-Amand<sup>1</sup>, Ellen Lye<sup>1</sup>, Julie Yome<sup>1</sup>, Orly Brion<sup>1</sup>, Trevor Satchwill<sup>1</sup>, Kim Irwin<sup>1</sup>*

*1. Health Canada, Ottawa, ON, Canada.*

**Abstract:** Pyrethroids are extensively used in agricultural, commercial and residential pest control, and are implicated in adverse health outcomes in humans. We evaluated the associations between socio-demographic and dietary factors and urinary concentrations of pyrethroid metabolites in the Canadian general population using data collected under the Canadian Health Measures Survey (CHMS) cycles 1 and 2 (2007-11), and assessed the data in a risk context using the screening-level biomonitoring equivalents for 3-phenoxybenzoic acid (3-PBA), a common metabolite of several pyrethroids. Data from CHMS cycles 1 and 2 were combined for the analyses. Regression analysis revealed significant ( $p < 0.05$ ) age-dependent differences in the least-square geometric mean (LSGM) concentrations of the sum of all measured pyrethroid metabolites, or 3-PBA (LSGM for 20-39 years > 12-19 years). The concentrations were also associated with sex (females > males), country of birth (other than Canada > Canada), body mass index (normal weight > obese), season (fall > summer), use of home/yard pesticides or lice/flea control products (yes > no), and frequency of consumption of vegetables (high > low) and starchy roots (low > high). The geometric mean concentrations of 3-PBA for all age and sex groups from CHMS cycles 1 and 2 did not exceed the Tier 1 screening value of 1.7  $\mu\text{g/L}$  based on the most stringent of the biomonitoring equivalents derived for the chronic dietary RfD (USEPA) and ADI (WHO/FAO/EC) suggesting that the cumulative exposures to pyrethroids in Canadians are low relative to guidance values, and existence of a margin of safety. Additional data on pyrethroid metabolites in Canadians from CHMS cycle 5 (2016-17) and cycle 6 (2018-19) will support an assessment of trends in exposure and future evaluation of risks.

## **S01.04.20. Screening of Population Level Biomonitoring Data from the Canadian Health Measures Survey in a Risk Based Context**

Annie St-Amand

*Annie St-Amand<sup>1</sup>, Cheryl Khoury<sup>1</sup>, Kate Werry<sup>1</sup>, Mike Walker<sup>1</sup>, Subramanian Karthikeyan<sup>1</sup>, Andy Nong<sup>1</sup>, Sean Hays<sup>2</sup>, Lesa Aylward<sup>2</sup>*

- 1. Healthy Environment and Consumer Safety Branch, Health Canada, Ottawa, ON, Canada.*
- 2. Summit Toxicology LLP, Lyons, CO, United States.*

Abstract: Canada's comprehensive and nationally-representative Canadian Health Measures Survey includes a biomonitoring component which has measured over 250 chemicals in approximately 29,000 Canadians over a ten-year period. Our capacity to interpret biomonitoring results in relation to the risks these levels pose to human health is gradually improving with the development of biomonitoring equivalents (BE) and human biomonitoring values (HBM values). Biomonitoring data from various cycles of the CHMS are compared with published BE values for chemicals with short half-lives, persistent chemicals, and volatile organic compounds (VOCs). Hazard quotients are calculated as the ratio of the biomarker concentration to the chemical-specific BE value using both the geometric mean (GM) and upper bound (95th percentile). Hazard quotients near or exceeding a value of 1 are indicative that exposure levels are near or exceeding the exposure guidance values on which BEs are based. For example, acrylamide is assessed by comparing levels of two of its metabolites in blood, namely AAVal and GAVal. Hazard quotients for AAVal exceed the BE at the 95th percentile for smokers. This exceedance is not seen in non-smokers. A similar pattern is observed for GAVal. Although more work will be needed to fully evaluate available Canadian human biomonitoring data against established guidance values, this screening exercise can help to prioritize risk management actions for some toxic chemicals and show the importance of continued biomonitoring to assess population exposures and exceedances.

## S01.04E. Clean Cooking Implementation Science to Understand Complex Determinants of Clean Fuel Technology Adoption

### **S01.04.21. Introduction: Implementation Science to Reduce Household Air Pollution (HAP) Exposures in Low and Middle-Income Countries (LMICs)**

Joshua Rosenthal

*Joshua P. Rosenthal<sup>1</sup>, Kalpana Balakrishnan<sup>2</sup>*

*1. Epidemiology and Population Studies, Fogarty International Center - NIH, Bethesda, MD, United States.*

*2. Environmental and Occupational Health, Sri Ramachandra University, Chennai, Tamil Nadu, India.*

**Abstract:** HAP exposures are responsible for a major proportion of the total disease burden in LMICs. To address this, the NIH led Clean Cooking Implementation Science Network (ISN) is developing methods to elucidate technologies, conditions, and implementation strategies that can result in the largest reductions in HAP exposures. The challenge is to accelerate widespread, sustained and nearly exclusive adoption of clean cooking to promote public health. In this symposium we present a brief introduction to the network and its approach, followed by study results from interventional and natural experiments in India and Sub-Saharan Africa. For example, India has recently launched an enormous effort to provide access to clean cooking fuels such as Liquefied Petroleum Gas (LPG) to nearly 50 million homes by 2019, but challenges of sustaining LPG use remain to be overcome. Implementation science has evolved precisely to meet this kind of complex, multidimensional problem. Finance, access to services, ambient air quality, climate, home construction, community structure, cultural traditions and gender are among the complex variables addressed in the network's research. The ISN projects presented here use a diversity of methods - including social network analysis, microfinance experimentation, novel survey methodologies and sensor-based monitoring of stove-use and resulting exposure levels - to understand the potential drivers of decision making in rural and peri-urban, low income settings. In this brief introduction to the research we provide background on the scope of the problem and an outline of the approaches we are taking to employ research that will accelerate the transition to clean cooking fuels around the world.

## **S01.04.22. Economic Experiments to Measure LPG Stove Demand and Impacts on Cooking Behaviors and Exposures in Northern Ghana**

Katherine Dickinson

*4. University of Colorado, Boulder, CO, United States.*

Abstract: The Prices, Peers, and Perceptions (P3) project in the Kassena-Nankana Districts (KND) of Northern Ghana is conducting field experiments to better understand factors influencing adoption and use of cleaner cooking technologies, and the contribution of cooking emissions to air quality and exposures in this region. In the urban areas of the KND, liquefied petroleum gas (LPG) stove-fuel packages are offered to randomly selected households using a one-on-one auction procedure. Our interdisciplinary study design and methods allow us to: 1) measure willingness to pay for different package components, such as the type of stove (one vs two burner), and fuel delivery method (home delivery vs at refilling station); 2) randomize distribution of these different packages to participants, at varying price levels; and 3) measure subsequent impacts on cooking behaviors (including use of LPG and traditional stoves), household air quality, and personal exposure to particulate matter.

## **S01.04.23. The Bottled Gas for Better Life Pilot: An Evaluation of the First Microfinance Initiative in Cameroon to Support Households Switch from Solid Fuel to LPG for Cooking**

Dan Pope

*Dan Pope<sup>1</sup>, Nigel Bruce<sup>1</sup>, James Higgerson<sup>2</sup>, Ryan T. Chartier<sup>3</sup>, Lirije Hyseni<sup>1</sup>, Sara Ronzi<sup>1</sup>, Debbi Stanistreet<sup>1</sup>, Bertrand Hugo Mbatchou Ngahane<sup>4</sup>, Elisa Puzzolo<sup>5</sup>*

- 1. Public Health and Policy, University of Liverpool, Bolton, United Kingdom.*

- 3. Research Triangle Institute, Durham, NC, United States.*
- 4. Douala General Hospital, Douala, Cameroon.*
- 5. Global LPG Partnership, New York, NY, United States.*

**Abstract:** Introduction the LPG Adoption in Cameroon Evaluation (LACE) studies aimed to identify and address barriers to adoption and use of liquified petroleum gas (LPG) as a clean fuel. This included evaluation of a microfinance scheme (paid back over 6 months) to fund an LPG start-up kit (stove, equipment and gas; US\$95), a barrier to adoption identified by LACE. We report here impacts on fuel-use practices, household air pollution exposure, acute health symptoms and burns in loan beneficiaries. Methods 110 beneficiaries completed household surveys prior to receiving the LPG start-up kit, and then again after the loan period. Additional surveys were completed by 500 households each from beneficiary and control communities. 48-hr PM<sub>2.5</sub> samples (kitchen concentrations and cook exposures) were measured in 35 beneficiary households at the two data collection periods using the RTI MicroPEM. Results Most households repaid the loan (89%), although 41% reported difficulty making repayments. After the loan, primary fuel use changed from wood (75%) and other biomass (15%) to LPG (79%), although no households used LPG exclusively. Levels of PM<sub>2.5</sub> declined from baseline to after the loan period for kitchen concentrations (geometric mean (GM) 337.9 µg/m<sup>3</sup> vs 32.3 p<0.0005) and cook exposures (GM=73.8 µg/m<sup>3</sup> vs 28.6 p<0.0005). Significant reductions in headaches (46% to 9%; p<0.0005), eye problems (66% to 8%; p<0.0005), cook burns (25% to 3%; p<0.0005) and child burns (9% to 0%; p<0.0005) were observed after the loan. An increase in primary use of LPG was observed in the beneficiary community (46% to 55%) not seen in controls (67% to 67%). Conclusion Successes of this loan pilot included (i) a high level of repayment and LPG use, (ii) reductions in household air pollution, self-reported health symptoms and burns and (iv) increased community adoption of LPG. Fuel stacking remains an ongoing issue. The pilot has informed a second phase involving 800 homes across five regions of Cameroon.

#### **S01.04.24. Understanding Household, Network, and Organizational Drivers of Adoption, Sustained Use, and Maintenance of Clean Cooking Fuels in Rural India**

Gautam Yadama

*Praveen Kumar<sup>1</sup>, Gautam Yadama<sup>1</sup>*

*1. Social Work, Boston College, Chestnut Hill, MA, United States.*

**Abstract:** To reduce household air pollution (HAP) the emphasis is now on transitioning households and communities to cleaner Liquefied Petroleum Gas (LPG) based cooking systems. The objective of our case-control study is to examine household, network, and organizational drivers that influence adoption and sustained use of LPG in Below Poverty Line (BPL) households in rural India. Our aims are: 1) understand how rural LPG adopters vary from other rural households on factors of affordability, accessibility, and awareness (3As) of LPG; 2) evaluate the relative influence of gender-based personal networks on LPG adoption in these rural households; and 3) determine how the 3As affect sustained use of LPG in adopter households. Our findings come from a multistage random sample in 35 habitations of rural Andhra Pradesh, India. Data for Aim 1 were collected through a set of semi-structured questionnaires administered to 510 households. For Aim 2 we used a standardized personal gender based network survey administered to 200 households. We are currently collecting data for Aim 3 by deploying stove use monitoring technologies to record cookstoves' usage patterns in real time for 65 households for one year. We will present our results for aim 1 and aim 2 from this ongoing study. Our findings show that 3As concurrently impact the adoption of LPG in poor rural households. Specifically, our results indicate the following factors are salient and have a positive effect on LPG adoption in rural India: 1) income of women; 2) income of households; 3) proximity to LPG distribution centers; 4) proximity to tarmac roads; 5) remoteness to freely available biomass from forests; and 6) awareness campaigns. Our findings also reveal the importance of structure and composition of personal gender-based networks in the uptake of LPG. Lessons from this study are timely, relevant, and of interest to Government of India's renewed emphasis on expanding LPG distribution to the poor in rural India.

#### **S01.04.25. Enhancing Usage of Clean Fuels among Pregnant Women in India**

Ajay Pillarisetti

*Ajay Pillarisetti<sup>1</sup>, Sudipto Roy<sup>2</sup>, Arun Dhongade<sup>2</sup>, Sathish Madhav<sup>3</sup>, Makarand Ghorpade<sup>2</sup>, Tracy Allen<sup>4</sup>, Kalpana Balakrishnan<sup>3</sup>, Sanjay Juvekar<sup>2</sup>, Kirk R. Smith<sup>1</sup>*

**Abstract:** Background. Recent Indian policies have vastly expanded access to clean fuels. Access does not necessarily lead to displacement of traditional stoves and fuels, however. We evaluated methods to encourage usage of LPG, including provision of subsidized and free fuel. We also explored recruiting women at marriage to cover the vulnerable time prior to typical detection of pregnancy. Methods. 150 pregnant women and 50 newly married couples were recruited through local accredited social healthcare activists (ASHAs). Participants were provided an LPG stove, related accessories, and two full LPG cylinders. Stove use monitors were installed on the primary traditional and stove and on both LPG burners. Households were asked to destroy or remove their traditional stoves upon receipt of the intervention package. Pregnancy arms included free fuel (n=50), fuel subsidized on usage (a conditional cash transfer or CCT, n=50), and a control arm (n=50). Newly married couples (n=50) were provided a stove and related accessories. PM exposures and kitchen concentrations were measured. Results. Over two-thirds of households either destroyed or removed their traditional stoves. The number of refills was much higher in the free fuel arm than in either the conditional cash transfer or control arms. Recruiting at marriage proved successful, with approximately 1/3 of households pregnant within 4 months of recruitment. Approximately 66% of households have purchased or will purchase their second LPG cylinder rather than return it to the study. Conclusions. Provision of free fuel during pregnancy fits well within Indian paradigms of providing services to poor households. Assuming detection in the third month of pregnancy, such a program would cost approximately 70 dollars per household for fuel. Expanding to newly married couples could cover vulnerable periods of pregnancy prior to typical detection. Providing a second cylinder appears valuable to households to smooth out supply issues.

## S01.04F. Climate, Air Pollution, and Environmental Health in Africa 2

### **S01.04.26. The Canaries in the Coal Mine of Climate Change Impacts: Understanding the Threats that Climate Change Poses to Respiratory Health of Workers**

Isabella Annesi-Maesano

*Isabella Annesi-Maesano<sup>1</sup>*

*1. EPAR IPLESP, INSERM & Sorbonne Université, Paris, France.*

Abstract: The aim of the presentation is to characterize how climate change may influence workers' allergic and respiratory health and safety and to establish plans for mitigating, responding, and adapting to the current and anticipated impacts. Workers are often the first to be exposed to the effects of climate change as they may be exposed to hazards for longer durations and at greater intensities than the rest of the populations due to their type of activities, geographic region, season, and duration of time they are outside. Climate change may result in not only the increasing prevalence and severity of known occupational hazards and exposures but also the emergence of new ones including allergic and respiratory diseases. When looking at allergic and respiratory health, hazards to which workers are particularly exposed and that are increasing due to climate change are physical (extreme heat and cold, air pollution, noise) and biological (vector-borne, pollen, molds, plants). Extreme heat and cold temperatures and air pollution are responsible for increased respiratory morbidity and mortality. In workers, extreme heat triggers asthma and extreme cold worsens COPD. Air pollution is an established trigger and cause of both asthma and COPD. Additionally, exposure to loud noise as source of stress exacerbates the effect of air pollution. More vector-borne respiratory diseases and allergies are expected. Increasing molds and pollen count and allergens will increase allergies. Thunderstorms tightening will enhance asthma occurrence due to pollen and mold sub-particles penetration in the airways. Finally, poisonous plants can cause allergic skin reactions and respiratory problems if their toxins are inhaled. Employers should train outdoor workers about their workplace hazards, including hazard identification and recommendations for preventing and controlling their exposures.

**Abstract:** Background: Indoor air pollution from solid fuels represents an important determinant of adverse health effects with 4.3 million premature deaths annually, and 3% of the global burden of disease. However, research on impacts of indoor air pollution on child development, including cognitive and behavioral development, is lacking. Objective: To investigate the association between children's exposure to indoor air pollution through solid fuel use (SFU) and early child development in low and middle-income countries (LMICs). Methods: We analyzed data on 102,007 children under 5 years from the multiple indicator cluster survey by UNICEF on 46 LMICs. A standardized global early child development index (ECDI) was calculated from questions on 4 developmental domains: physical, learning, social-emotional and literacy-numeracy. SFU was defined as cooking with coal/lignite, charcoal, wood, straw/shrubs/grass, animal dung, agricultural crop. We used multilevel regressions to investigate associations between SFU and ECDI by country, pooled by geographical region, and pooled globally. Results: Between 0.3% (Tunisia) and 99.5% (Central Africa) reported SFU. Overall, 31% of children were not developmentally on track. Associations between SFU and ECDI were heterogeneous across countries, and higher in Africa. Children with SFU had 0.25 standard deviation (SD) (95% CI: -0.31, -0.18), 0.27 SD (95% CI: -0.32, -0.21), 0.13 (95% CI: -0.22, -0.05), and 0.07 (95% CI: -0.14, 0) decreased ECDI scores in West & Central Africa, Middle East & North Africa, South Asia, and Latin America regions, respectively. No associations were observed for the Eastern European, East Asia and Pacific, and Eastern & Southern Africa regions. Globally, SFU was associated with 0.11 SD (95% CI: -0.18, -0.04) decrease in standardized ECDI scores. Conclusions: Although current SFU was used as a proxy and explicit exposure measurements were lacking, we found evidence that SFU negatively impacts children's early development

#### **S01.04.28. Outdoor Air Pollution in the City of Abidjan (Côte D'Ivoire): From Pollutant Concentrations to Diseases in Hospitals**

Kouame Kouadio

*Kouame Kouadio<sup>1</sup>*

*1. Environment and health , Institut Pasteur of Côte d'Ivoire, Abidjan, Côte d'Ivoire.*

**Abstract:** Background Air quality is a major concern due to its impact on human health. In order to assess the impact of air pollution on health, a survey was carried out during 2 years. The pollutants' concentrations were also estimated. PM<sub>2.5</sub> concentrations were recorded in regard to hospital admissions in order to estimate a relationship between the occurrence of the diseases and pollutants concentrations. The survey was conducted from the 2nd July 2015 to 23rd February 2017 during rainy and dry season. Daily data of patients with cardiovascular, respiratory and skin diseases from five health centers of palmeraie and Akouédo village in the municipality of Cocody, Community Hospital and Soeur Catherine hospital in Yopougon and general hospital in Adjame were recorded. Results 10,593 patients with respiratory diseases, cardiovascular and skin diseases were recorded. 54 % were female. 57% of them were under 20 years old. Concerning diseases, final diagnosis showed that 67% had respiratory diseases. Seasonal average concentrations were observed for pollutants. PM<sub>2.5</sub> concentration average was 32±24 µg/m<sup>3</sup> for traffic, 28±19 µg/m<sup>3</sup> for waste burning and 145±69 µg/m<sup>3</sup> for domestic fire; which were higher than those recommended by WHO guidelines for air quality. Correlation between hospital admission and pollutants concentrations were not observed. **Conclusions** This study is an original database to characterize urban air pollution and a first attempt toward hospital admission in the metropolis of Abidjan. This work should draw the attention of the stakeholders to the necessity of air quality monitoring in order to define national standards and to better control the pollutants' emissions and to investigate the impact on the health of the growing population of developing African countries.

#### **S01.04.29. A Time Series Analysis of Morbidity and Mortality of Lung and Cardiovascular Diseases in Kampala, Uganda**

Samuel Etajak

*Samuel Etajak<sup>1</sup>*

*1. Department of Disease Control and Environmental Health Science, Makerere University School of Public Health, Kampala, Uganda.*

**Abstract:** Burden of disease attributable to non-communicable diseases (NCD) is increasing worldwide. World Health Organization 2017 report estimated 40 million deaths occur per year worldwide, and that 31 million of all these deaths occur in low and middle income countries. We provide preliminary analysis to ascertain morbidity and mortality of Lung and Cardiovascular Diseases in Kampala, Uganda. We collected data on morbidity and mortality from 3 hospitals in 2 sub cities of Kampala. These hospitals were selected on the basis of providing adequate data for emergency and regular admissions, and discharge hospital services (improved or follow up or death), serving a larger geographical catchment area, potential availability of complete data, and the presence of in house IRB in each hospital. Data from the hospitals was collected from Health Management System (HMIS) using the data abstraction from 1st September to 31st December 2017. We collected data on the health outcomes related to cause of illnesses (morbidity) and cause of deaths (mortality). Individual level variables included age, sex, date of admission, cause admission, date of discharge, cause of death, and address of the patient were analyzed using descriptive statistics. Overall 870 patients were studied and of these 53% (463/870) of the patients were male as compared to the females. The mean age was 30 years (range=0-97 years). Majority 78% (676/870) patients had respiratory related conditions, of these 51% (347/870) were children aged 0-9 years. Cardiovascular related conditions were notably higher adults  $\geq 40$  years. The most reported cardiovascular related conditions in adults were stroke and cardio pulmonary failure. The commonest cardiovascular conditions are stroke and cardio vascular failure and pneumonia is a dominant respiratory condition in children The findings will help to generate road maps and action by governments and implementing partners in control the NCD diseases in cities.

## S01.04G. Emerging Evidence on Exposures to Ultrafine Particles

### S01.04.31. Personal Exposures to Ultrafine Particles among Asthmatic Kids: Differences between UFP and PM2.5

Kirsten Koehler

Abstract: Particulate matter (PM) air pollution is known to exacerbate asthma symptoms in children; however, it is still unclear which metric (particle size, morphology or chemical composition) of PM is most relevant to respiratory health. Most studies have focused on the health impacts of fine PM (PM<sub>2.5</sub>, particles with diameter less than 2.5  $\mu\text{m}$ ), yet recent evidence suggests that health effects may be more strongly related to the ultrafine particulate (UFP) portion of PM exposure. Due to complexities of exposure assessment and the lack of a regulatory monitoring network for UFP, few epidemiologic studies have evaluated the relationship between UFP and respiratory health. The aim of this work is to determine which factors of PM exposure, including UFP, microenvironment, and peak exposure, are associated with respiratory effects. We conducted personal exposure assessment in a panel of 15 children with asthma, each of whom were followed for 7 days with 4 days of continuous monitoring of PM (10-s resolution), geographic location via GPS, biomarkers (urinary LTE<sub>4</sub>), and 7 days of asthma symptoms reported via text message. Ultrafine PM was measured using a Partector (expressed as lung deposited surface area; CH Technologies) and fine PM mass was measured with a MicroPEM (RTI International). Inner-city children were exposed to levels of PM mass often exceeding WHO recommendations for PM<sub>2.5</sub> in indoor air (24-hr mean (N=58): 23.6  $\mu\text{g}/\text{m}^3$ ; range: 1.4-132.2  $\mu\text{g}/\text{m}^3$ ). Ultrafine particle exposures (24-hr mean (N=58): 37  $\mu\text{m}^2/\text{cm}^3$ ; range: 3-185  $\mu\text{m}^2/\text{cm}^3$ ) typically varied over 2 orders of magnitude within 24-hours and showed relatively low correlation with PM<sub>2.5</sub> (mean Pearson coefficient of 1-minute measurements across 58 sampling days was 0.29). Exposures to ultrafine particles tended to be highest at home during exposure to secondhand smoke and cooking events. Exposures while commuting were also high, especially when walking.

### **S01.04.32. Using Real-Time Personal Monitoring and Ecological Momentary Assessment to Study Ultrafine Particles and Children's Health**

Patrick Ryan

*Patrick Ryan<sup>1</sup>, Haley M. Beavers<sup>1</sup>, Christopher Wolfe<sup>1</sup>*

*1. Division of Biostatistics and Epidemiology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, United States.*

**Abstract:** Background: Few studies have examined the health effects of ultrafine particles (UFPs), in part due to challenges in assessing exposure. The objective of the Ecological Momentary Assessment and Personal Particle Exposure Study (EcoMAPPE) is to characterize adolescents' personal exposure to UFPs and examine their association with respiratory health. Methods: Participants (ages 13-17) complete two sampling periods of seven days. On each sampling day, personal UFP exposure is measured at one-second intervals for three hours using a wearable UFP monitor (PUFP C200, EnMont, LLC). Ecological momentary assessment (EMA) data is collected using a smartphone app that prompts participants to answer brief surveys based on time, location, and activity. Participants may also record locations where they perceive elevated exposure and can upload images to provide a visual depiction of their environment. Additional sensors include the collection of GPS data; a Fitbit Charge 2 to monitor heart rate, sleep quality, and activity; and a Spirobank Smart to record lung function throughout the sampling period. Results: To date, 24 participants have enrolled in the study and, collectively, completed 458 hours of personal sampling. Personal exposure to UFP was highly variable; participants' median UFP exposures over their seven-day sampling period ranged from 1,140 - 13,000 particles / cm<sup>3</sup> (p/cc). Similarly, the 95th percentile of UFP exposure ranged from 13,600 to > 150,000 p/cc. Participants completed 1,012 EMA surveys; of these 51% were completed at home, 9% at school, 23% while in transit, and 17% at other locations. Participants recorded FEV<sub>1</sub> and peak flow 3.25 times per day, on average. Conclusions: Personal air pollution monitors, EMA, and other sensors enable the examination of short-term UFP exposure and respiratory health in adolescents.

### **S01.04.33. Ultrafine Particle Exposures in a Population of Former Smokers with COPD**

Meredith McCormack

*Meredith McCormack<sup>1</sup>, Ehsan Majd<sup>2</sup>, Kirsten Koehler<sup>2</sup>, Nadia Hansel<sup>1</sup>*

*1. Medicine, Johns Hopkins University, Baltimore, MD, United States.*

*2. Environmental Health Sciences and Engineering, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States.*

**Abstract:** Chronic Obstructive Pulmonary disease (COPD) is the third leading cause of death in the United States, affecting over 10 million adults, and the fifth leading cause of death worldwide. Mortality attributable to COPD is projected to increase and those with COPD suffer high morbidity, including poor quality of life, activity limitation and exacerbations leading to ED visits and hospitalizations. Individuals with COPD are susceptible to the health effects of air pollution. Exposure to indoor PM<sub>2.5</sub> has been associated with respiratory symptoms and increased risk of exacerbation. However, little is known about whether there is an independent effect of ultrafine particles on COPD morbidity. To study indoor UFP and COPD outcomes, in-home monitoring of UFP has been conducted in the homes of 35 non-smoking adults with COPD for 1-week periods. This monitoring has been done concurrently with PM<sub>2.5</sub> and NO<sub>2</sub> monitoring, providing a holistic look at air pollution exposures in this potentially susceptible population. This cohort is well characterized, comprised of former smokers with impaired lung function indicating moderate to severe COPD. Respiratory questionnaires and lung function have been obtained with simultaneous monitoring of in-home air pollution at 3 and 6 months after enrollment. Peak UFP exposures are highly correlated with cooking events and exposures typically vary over 2 orders of magnitude within a day. We will evaluate the independent effects of UFP on respiratory morbidity in this cohort of former smokers with COPD.

### **S01.04.34. Joint Effects of Long-Term Exposure to Ultrafine Particles and Nitrogen Oxides on Cardiovascular Risk Factors over Six Years among an Environmental Justice Population**

Laura Corlin

*Laura Corlin<sup>1</sup>, Matthew C. Simon<sup>2</sup>, John Durant<sup>1</sup>, Jonathan Levy<sup>2</sup>, Katherine Tucker<sup>3</sup>, David Gute<sup>1</sup>, Doug Brugge<sup>4</sup>, Mark Woodin<sup>1</sup>*

- 4. Public Health and Community Medicine, Tufts University, Boston, MA, United States.*

**Abstract:** Background: No previous studies have examined the cardiovascular effects of interactions between long-term exposure to ultrafine particles (UFP, measured as particle number concentration or PNC) and nitrogen oxides (NOx). We assessed independent and joint effects of PNC and NOx on cardiovascular risk factors in a longitudinal study of Puerto Rican adults living in Boston (MA, USA). Methods: Over 940 participants attended up to 3 study visits over 6 years. Annual average PNC and NOx exposures were assigned using a model accounting for spatial (<200 m) and temporal patterns. We used multilevel linear models with random intercepts for each participant to examine the independent and joint effects of normalized PNC and NOx on systolic blood pressure (SBP), diastolic blood pressure (DBP), pulse pressure (PP), and an inflammation biomarker (high sensitivity C-reactive protein or CRP). Results: Median PNC was 21000 particles/cc (inter-quartile range (IQR) = 11000 particles/cc) and median NOx was 45 ppb (IQR = 12 ppb) for our participants (mean baseline age = 57 yrs, sd = 7.5; >70% female; 52% with >8th grade education). PNC was independently associated with DBP ( $\beta = 0.53$ , 95%CI = 0.09, 0.96 mmHg). NOx was independently associated with SBP ( $\beta = 1.18$ , 95%CI = 0.20, 2.16 mmHg), DBP ( $\beta = 1.02$ , 95%CI = 0.49, 1.55 mmHg), and lnCRP ( $\beta = -6.3$ , 95%CI = -13.3, 0.6% change). People exposed to high levels of both pollutants had higher SBP ( $\beta = 1.66$ , 95%CI = -0.08, 3.39 mmHg) and DBP ( $\beta = 2.47$ , 95%CI = 1.51, 3.43 mmHg) than people exposed to low levels of PNC and NOx. An interaction term for PNC and NOx was significant and indicative of antagonistic effects on DBP. There were no effects of PNC or NOx on PP. Sex, smoking status, and baseline hypertension status modified the independent and joint effects. Conclusion: Long-term exposure to PNC and NOx have independent and joint associations with blood pressure levels over six years. There is less evidence that the pollutants affect CRP.

## S01.04H. Updates on the CKDu Epidemic and New Directions for Coordinated Research

### **S01.04.35. Longitudinal Study of Workers in El Salvador & Nicaragua: Opportunities for Collaboration**

Madeleine Scammell

- 5. Nephrology, Harvard Medical School/Beth Israel Deaconess Medical Center, Boston, MA, United States.*

**Abstract:** The causes of the epidemic of chronic kidney disease (CKD) in Central America, referred to as Mesoamerican Nephropathy (MeN), or CKD of non-traditional etiology (CKDnt), are unknown. Sugarcane workers in both El Salvador and Nicaragua are at high risk of developing the disease. However, the disease is not unique to sugarcane, nor is it limited to agricultural workers. The disease is also known to affect men of working age engaged in other sectors involving manual labor. An ongoing longitudinal study in both countries of workers in sugarcane, corn, plantain and construction will measure exposure to heat as well as a variety of nephrotoxins including pesticides and metals. The MesoAmerican Nephropathy Occupational Study (MANOS) will include a short-term exposure assessment characterizing occupational risk factors and baseline health status, and follow workers over time to monitor long-term kidney function. The presentation will emphasize aspects of the study design that allow for analyses of multiple exposures and end points, and opportunities for collaboration.

### **S01.04.36. Chronic Kidney Disease in a Multiethnic Rural Population in the United States: Translating Research from Tropical Regions**

Katherine James

*Katherine A. James<sup>1</sup>, Camille Marsh<sup>2</sup>, Amber Vaughn<sup>1</sup>, Richard Johnson<sup>3</sup>, Richard Hamman<sup>1</sup>*

- 1. Colorado School of Public Health, Aurora, CO, United States.*
- 2. National Jewish Hospital, Denver, CO, United States.*
- 3. University of Colorado, Aurora, CO, United States.*

Abstract: Chronic kidney disease is a global public health concern which can lead to end stage renal disease. Known risk factors have been unable to account for all the variability in chronic kidney disease risk especially in tropical areas where an emerging epidemic is occurring. Therefore, research has expanded into examining environmental exposures as potential risk factors for chronic kidney disease. These include climate factors such as heat stress and dehydration, drinking water quality (metals, hardness, silica, fluoride), pesticide exposure (glyphosate), and health risk behaviors (smoking, non-steroidal anti-inflammatory drug use). In consideration of these factors, we are investigating the association between environmental exposure to metals and clinical and preclinical kidney disease in the San Luis Valley Diabetes Study cohort with longitudinal physiologic and behavioral data. We estimated cumulative cadmium exposure for individual study subjects using historically collected urine samples and arsenic exposure from residential drinking water based on a previously validated method. We also considered other pathophysiologic factors including diet, smoking, physical activity, family history, diabetes mellitus, hypertension, specific drug use, occupation and other contributing medical factors. If an association is identified between metal exposure and clinical and preclinical kidney disease, it can help elucidate the pathophysiology with possible linkage to the emerging epidemic in tropical regions.

**S01.04.37. Chronic Kidney Disease in El Salvador and Mesoamerica: Fostering Collaborations to Respond to the Epidemic**

Ramon Garcia Trabanino

*Ramon Garcia Trabanino<sup>1</sup>, Emmanuel R. Jarquin<sup>2</sup>*

*1. Centro de Hemodialisis, San Salvador, El Salvador.*

*2. AGDYSA, San Salvador, El Salvador.*

Abstract: Dr. Garcia Trabanino is the head of the Association of Nephrology of El Salvador and a board member of the CENCAM, the Consortium of researchers studying the Epidemic of Mesoamerican endemic Nephropathy (MeN) in Central America and Mexico. He will discuss research on MeN nationally and regionally, on pesticides and heat stress, as well as collaborations with community groups in El Salvador, including the Emergency Social Fund for Health (ESFH) of the town of Tierra Blanca, at the Bajo Lempa region in El Salvador, a community-based organization focused on early identification and treatment of the disease. This presentation will summarize 20 years of research history and collaborations, along with relevant clinical aspects of this new disease, including the ESHF community registry of end-stage renal disease and protocol for diagnosis and treatment of patients with MeN.

## **S01.04.38. Shining a Light on Sri Lankan CKDu: Opportunities for International Collaboration**

Keith Levine

*Keith E. Levine<sup>1</sup>, Jennifer H. Redmon<sup>2</sup>, Myles Elledge<sup>2</sup>, Rajitha Wickremasinghe<sup>3</sup>, Kamani Wanigasariya<sup>4</sup>, M. Pathmalal<sup>4</sup>, James Harrington<sup>1</sup>, Reshan A. Fernando<sup>1</sup>*

- 3. University of Kelaniya , Kelaniya , Sri Lanka.*
- 4. University of Sri Jayewardenepura, Nugegoda, Sri Lanka.*

Abstract: Chronic kidney disease (CKD) has emerged as an important non-communicable, global health epidemic. Importantly, CKD is becoming increasingly prevalent in the developing world where diagnosis and treatment of renal disease is consuming a significant and growing portion of healthcare resources. In the 1990s, an apparently new form of CKD of unknown etiology (CKDu) began to emerge in Sri Lanka's North Central Province (NCP), located within the island nation's dry zone. It is slowly progressive, initially asymptomatic, and irreversible, directly impacting approximately 30K people to date, and growing. Sri Lankan CKDu is also characterized by renal tubular/interstitial damage, primarily burdening people of lower socioeconomic status working or living in agricultural areas. This presentation will review findings from CKDu field work in Sri Lanka (2013-14 and 2017) in targeted geographic areas. Biological (blood and urine) and environmental samples (drinking water, rice, soil and freshwater fish) from endemic areas in Sri Lanka were analyzed to determine the concentration of a suite of heavy metals and trace element nutrients, along with qualitative research of household health and farming practices. A broad panel, mineralomics approach was used to shed light on potential geochemical risk factors associated with CKDu.

Tuesday, August 28

WHO Global Strategy on Health, Environment and Climate Change

*Maria Neira, World Health Organization (WHO), Director for the Department of Public Health, Environmental and Social Determinants of Health*

Abstract: Environmental risk factors cause about one quarter of deaths world-wide, amounting to 13 million deaths each year. Ambient and household air pollution together cause 7 million deaths per year. 829,000 annual deaths still results from easily preventable risks linked to poor water, sanitation and hygiene. A large fraction of malaria, dengue and other vector diseases are closely linked to aquatic environments. Adverse health impacts from chemicals are continuously identified. Over half of the world population live in urban areas, which will increase to over 70% by 2050. The threats of climate change to health are multi-faceted and rapidly increasing in intensity. A transformative approach is needed to address environmental risks to health at their root, at the level of policy setting, in an integrated way. Sectors which define policies highly impacting on population health include the energy, transport, land use planning, housing, water and sanitation, labour and industry. Accumulating evidence on impacts and solutions and the Sustainable Development Goal (SDG) Agenda are creating the opportunity for change. Evidence on notable successes from solutions to critically reduce this burden has increased, and is showing high returns from investments in safer environments. Our vision is an overarching framework and set of governance mechanisms and leadership for health, and stepped up, broad intersectoral stakeholder engagement and action to implement health-supportive policies. Such actions are to be based on a solid evidence base of health impacts and solutions, and informed by regular monitoring and tracking. New research connected to interventions in health-relevant areas, implementation science and participatory policies are necessary to accelerate the attainment of the SDGs. Research, together with strengthened advocacy, communication and awareness raising around the co-benefits from actions on health, environment and climate change is essential to trigger for long-term sustainable solutions.

## How Can Birth Cohort Studies Contribute to Knowledge and Policies of the World to Reduce Risks of Emerging Contaminants?

*Shoji Nakayama, National Institute for Environmental Studies, Japan*

**Abstract:** A number of epidemiologic studies have revealed the environment can affect child health and development. Exposure to specific chemical substances during foetal and early childhood may cause health problems in later life. Children have unique exposure characteristics such as specific routes of exposure (e.g. through placenta and breastfeeding), exploratory behaviours (e.g. hand-to-mouth, object-to-mouth, pre-ambulatory and high-risk behaviours) and specific physiology (e.g. high oxygen demand, high breathing rate, low stature and high surface area to volume ratio). Understanding how children expose to harmful environment qualitatively and quantitatively and how the exposure associates with child health and development is essential for children's environmental health. Contaminants of emerging concern (CECs) in human health context are groups of chemical substances that existed in the past but with new concern and that are introduced to market recently and concerned to have potentially harmful effects. For example, lead is a legacy contaminant but has posed new concern about its effect on child neurological development at relatively low exposure. Particulate matter is not a single chemical but a long-lasting pollutant that appears to affect children's lung function at low level exposure. Algal toxins are another legacy group of chemicals with new health concern. Examples of newly introduced chemicals include pesticides, pharmaceuticals and personal care products, fragrances, plasticisers, hormones, flame retardants, nanoparticles, poly- and perfluoroalkyl compounds, chlorinated paraffins, siloxanes and various trace elements including rare earths. To better characterise the effect of the CECs on child health and development, many researches have been initiated in Asian countries as well as North America and Europe. Some studies look at a single to few CECs and others do many CECs simultaneously. Some studies characterise foetal exposure and others start from birth. Some studies evaluate health outcomes in trajectory, e.g. growth curves and changes in developmental scores. Some uses advance statistical methodologies to analyse the effect of multiple contaminants that potentially correlate each other. In this presentation, a potential of birth cohort studies on addressing risks of CECs will be discussed.

**Abstract:** Background Evidence remains equivocal regarding the association of inflammation, a precursor to cardiovascular disease, and acute exposures to ambient air pollution from traffic-related particulate matter. Though youth with type 1 diabetes are at higher risk for cardiovascular disease, the relationship of inflammation and ambient air pollution exposures in this population has received little attention. Objectives Using five geographically diverse US sites from the racially- and ethnically-diverse SEARCH for Diabetes in Youth Cohort, we examined the relationship of acute exposures to PM<sub>2.5</sub> mass, Atmospheric Dispersion Modeling System (ADMS)-Roads traffic-related PM concentrations near roadways, and elemental carbon (EC) with biomarkers of inflammation including interleukin-6 (IL-6), c-reactive protein (hs-CRP) and fibrinogen. Methods Baseline questionnaires and blood were obtained at a study visit. Using a spatio-temporal modeling approach, pollutant exposures for 7 days prior to blood draw were assigned to residential addresses. Linear Mixed Models for each outcome and exposure were adjusted for demographic and lifestyle factors. Results Among the 2566 participants with complete data, fully adjusted models showed positive associations of EC average week exposures with IL-6 and hs-CRP, and PM<sub>2.5</sub> mass exposures on lag day 3 with IL-6 levels. Comparing the 25th and 75th percentiles of average week EC exposures resulted in 8.3% higher IL-6 (95%CI: 2.7%,14.3%) and 9.8% higher hs-CRP (95%CI: 2.4%,17.7%). We observed some evidence of effect modification by gender for PM<sub>2.5</sub> mass exposures with hs-CRP and by race/ethnicity for EC. Conclusions Inflammation was associated with PM<sub>2.5</sub> mass and traffic-related air pollution in this study population of youth with type 1 diabetes. Thus youth with type 1 diabetes may be at increased risk of cardiovascular outcomes in areas with poorer air quality. The racial/ethnic and gender differences observed deserve further exploration.

## **O02.01.02. A Longitudinal Cohort Study on the Association between Long-Term Exposure to Ambient Fine Particulate Matter (PM2.5) and Diabetes Development**

Xiang Qian Lao

*Xiang Qian Lao*<sup>1</sup>

*1. The Chinese University of Hong Kong, Hong Kong, Hong Kong.*

**Abstract:** A longitudinal cohort study on the association between long-term exposure to ambient fine particulate matter (PM2.5) and diabetes development Xiang Qian Lao 1, \*, Cui Guo 1; Yacong Bo 1 ; Zilong Zhang 1 1. School of Public Health and Primary Care, the Chinese University of Hong Kong, Hong Kong Background There is limited information on the effects of long-term exposure to PM2.5 on the development of diabetes, especially in the WHO Western Pacific and South-East Asia regions, where many countries are experiencing high levels of air pollution. This study aimed to investigate the association between PM2.5 and incident diabetes using a large-scale longitudinal cohort study in Taiwan. Method We recruited around 150,000 participants at least 18 years of age between 2001 and 2014. Each participant received at least two measurements of fasting plasma glucose (FPG). Incident diabetes was identified as FPG $\geq$ 126 mg/dl, or self-reported physician-diagnosed diabetes. We estimated PM2.5 concentrations at each participant's address using a satellite-based spatiotemporal model with a resolution of 1  $\times$  1 km<sup>2</sup>. We performed Cox regression models with time-dependent covariates to analyse the effects of long-term to PM2.5 on the incidence of diabetes. Results Every 5- $\mu$ g/m<sup>3</sup> increase in PM2.5 was associated with a 5% higher risk of diabetes (hazard ratio [HR]: 1.05; 95% confidence interval [CI]: 1.03 to 1.07). Compared with the participants who exposed to the 1st quartile of PM2.5, participants with the exposure to the 2nd, 3rd and 4th quartiles of PM2.5 had HRs of 1.26 (95% CI: 1.17 to 1.37), 1.27 (95% CI: 1.17 to 1.37) and 1.15 (95% CI: 1.06 to 1.25), respectively, in the incidence of diabetes. Participants who drank occasionally or regularly (more than once per week) and had a lower body mass index (<23 kg/m<sup>2</sup>) were more sensitive to the effects of long-term exposure to ambient PM2.5. Conclusion Long-term exposure to ambient PM2.5 is associated with an increased risk of diabetes development.

### **O02.01.03. Long-Term Exposure to Ambient PM2.5 and Incidence of Diabetes in China: A Cohort Study**

**Abstract:** Background: Fine particulate matter (PM2.5) exposure has been linked to increased risk of various diseases. However, associations between air pollution and the chronic development of diabetes were rarely reported, especially in China. In this work, a cohort-based study was conducted to assess the incidence of diabetes associated with long-term exposure to ambient PM2.5. Methods: We collected health data and risk factors from the project of Prediction for Atherosclerotic Cardiovascular Disease Risk in China (China-PAR Project), with a sample of 127,840 Chinese adults aged 35 to 74 years studied. To match our PM2.5 exposure data, follow-up information from 2004 to 2015 was analyzed. Individual levels of PM2.5 exposure were estimated from satellite-based PM2.5 concentrations at 10 km resolution. Time-weighted average level based on each subject's geocoded addresses during the study period was presented as the long-term exposure of PM2.5. Cox proportional hazards model was employed to estimate the incidence of diabetes attributable to long-term exposure of PM2.5, with age, gender, smoking status, education level, body mass index and long-term levels of temperature and relative humidity adjusted. Nested random intercept of study cohorts and clusters were fitted in the model. Results: With 553,303 person-years of follow-up after 2004, the incidence of diabetes was 11.5 and 11.6 per 1000 person-years in men and women, respectively. For an increase of 10 µg/m<sup>3</sup> in long-term PM2.5 exposure, the adjusted percent increase in the incidence of diabetes was 15.05% (95% confidence interval: 6.10%, 24.75%). The increases were larger among the women, non-smokers and the subjects who were living in rural areas. Conclusions: Long-term exposure to ambient PM2.5 is a risk factor for diabetes in China. A sustained improvement of air pollution may benefit for the reduction of diabetes incidence in population.

**O02.01.04. Associations between Traffic-Related Air Pollution and Cardiovascular Disease Risk Factors Were Stronger in More Walkable Neighborhoods: The Cardiovascular Health in Ambulatory Care Research Team (CANHEART)**

Nicholas Howell

*Nicholas Howell<sup>1</sup>, Jack V. Tu<sup>1</sup>, Rahim Moineddin<sup>2</sup>, Anna Chu<sup>3</sup>, Hong Chen<sup>5</sup>, Perry Hystad<sup>4</sup>, Gillian L. Booth<sup>1</sup>*

*5. Public Health Ontario, Toronto, ON, Canada.*

**Abstract:** Introduction Studies suggest living in a more walkable neighborhood may protect against cardiovascular disease risk factors such as hypertension (HTN) and diabetes mellitus (DM) by encouraging physical activity. Walkable neighborhoods, however, often carry higher levels of traffic-related air pollution. Little is known regarding whether synergistic effects may exist between walkability and air pollution on these risk factors. Hypothesis We hypothesized that the association between traffic-related air pollution, hypertension, and diabetes mellitus would be stronger in more walkable areas. Methods We drew a cross-sectional sample of individuals ages 40-74 on January 1, 2008 from the CANHEART cohort. HTN and DM were ascertained using validated algorithms. Walkability (quintiles, Q5 highest, Q1 lowest) was measured using a validated index which has previously been shown to be inversely associated with obesity and diabetes. Exposure to nitrogen dioxide, a valid marker for traffic-related air pollution, was assessed using a land use regression models. The associations were tested using logistic regression with cluster-robust standard errors, adjusting for age, sex, area-level income, ethnicity, and comorbidities. Results 2,618,584 individuals were included in the analysis. Walkability was inversely associated with odds for HTN (Q5 vs. Q1 OR = 0.80, 95% CI: 0.79, 0.82) and DM (Q5 vs. Q1 OR = 0.89, 95% CI: 0.87, 0.91), while NO<sub>2</sub> was positively associated with each (HTN: OR = 1.02 per 10 ppb (1.01, 1.03); DM: OR = 1.11 per 10 ppb (1.09, 1.13)). We observed significant interactions between walkability and NO<sub>2</sub> on odds for HTN and DM, with stronger NO<sub>2</sub> associations in the most walkable neighborhoods. Conclusions We observed significant interactions between traffic-related air pollution and walkability on odds for HTN and DM. This finding suggests that benefits from living in more walkable neighborhoods may be partially offset by stronger negative associations with air pollution.

## **O02.01.05. Childhood Type 1 Diabetes: An Environment Wide Association Study across England**

Annalisa Sheehan

*Annalisa Sheehan<sup>1</sup>, Daniela Fecht<sup>1</sup>, Anna Freni Sterrantino<sup>1</sup>, Susan Hodgson<sup>1</sup>*

*1. Epidemiology & Biostatistics, Imperial College London, London, United Kingdom.*

**Abstract: Background/Aim:** Type 1 Diabetes (T1D) is an autoimmune disease with ~400,000 people currently affected across the UK. T1D results from gene-environment interactions, with environmental factors likely triggering the disease process in genetically susceptible individuals. We aim to assess the influence of a wide range of environmental factors on childhood T1D incidence in England, using an agnostic Environment Wide Association Study (EWAS) approach. **Methods:** We undertook an ecological EWAS at the Local Authority District (LAD) level (average ~140,000 persons, N=354) using incident T1D data derived from the national inpatient Hospital Episode Statistics. We assessed the association of LAD-level T1D incidence with a range of environmental exposures including meteorological, demographic, land use and pollution variables. Associations were assessed via Negative Binomial regression, using the age-sex adjusted expected counts as the offset. **Results:** Over the study period April 2000 - March 2011, there were 13,948 eligible T1D cases aged 0-9 years old. Case counts by LAD varied from 1 to 236; with a median 33 (Inter Quartile Range: 24-46), with an overall incidence of 21.2 (95% CI 20.9-21.6) per 100,000. The EWAS indicated that 25 out of the 58 environmental exposures were significantly associated with T1D incidence after adjusting for multiple testing using the Bonferroni correction. These included the air pollutants particulate matter (PM<sub>10</sub>, PM<sub>2.5</sub>), nitrogen dioxide, carbon monoxide as well as light at night pollution, UV radiation, lead in soil, population density and ethnicity. **Conclusions:** Our analysis contributes to evidence that a range of environmental exposures are associated with T1D in children in England. Variables identified as associated with T1D incidence via this agnostic, hypothesis generating, ecological EWAS approach are being further assessed at the individual level in a case control study.

## 002.01B. Air Pollution Related Hospitalization, Mortality, and Life Expectancy

### **002.01.06. Mortality and Hospitalization Linked to Fine Particulate Matter in Canada: Is There a Trend in Risk between 2001 and 2012?**

Hwashin Shin

*Hwashin H. Shin<sup>1</sup>, Harun Kalayci<sup>1</sup>, Lani Haque<sup>1</sup>, Marc Smith-Doiron<sup>1</sup>, Branka Jovic<sup>1</sup>, Wesley S. Burr<sup>2</sup>, Dave Stieb<sup>1</sup>*

*1. Health Canada, Ottawa, ON, Canada.*

*2. Trent university, Peterborough, ON, Canada.*

**Abstract:** Background: The Air Health Trend Indicator is designed to estimate public health risk related to short-term exposure to air pollution and to detect trends in annual national health risks. Trends in risk may reflect changes over time in population susceptibility or in composition of fine particulate matter or more generally in the air pollution mix. Design: Daily PM<sub>2.5</sub>, mortality, morbidity, and weather data for 22 cities (about 50% of the total population) were collected for 2001-2012. A Bayesian hierarchical model was employed to estimate annual national associations by season, lag of effect, sex and age group ( $\leq 65$  vs  $>65$ ). Circulatory (ICD\_I00-I99) and respiratory (ICD\_J00-J99) causes were examined for both mortality and morbidity (hospital admissions). Results: Annual population weighted PM<sub>2.5</sub> concentrations decreased gradually by 14% from 8 to 7  $\mu\text{g}/\text{m}^3$  nationally over the 12 year period. While population has increased by 13%, the ratios of mortality and morbidity to the population have decreased by 6% and 14%, respectively. In relation with PM<sub>2.5</sub> both mortality and morbidity showed higher circulatory risk for cold season, higher respiratory risk for warm season, higher risk for seniors ( $>65$ ), and sex-specific differences. Females were at higher risk (1.9% vs 1.1% per 1  $\mu\text{g}/\text{m}^3$ ) for circulatory mortality but males were at higher risk (0.26% vs 0.02%) for respiratory morbidity. No apparent trends were observed in PM<sub>2.5</sub> risk over time. Discussions: Despite downward trends in PM<sub>2.5</sub> concentrations, mortality and morbidity rates, there was no apparent trend in PM<sub>2.5</sub> risk. The 12-year period may be not long enough to detect trends if they exist. While the age difference in risk has been consistently reported, the sex difference has been inconsistent and thus needs further investigation. These findings could differentiate adverse effects of PM<sub>2.5</sub> on mortality and morbidity by identifying sub-populations susceptible to PM<sub>2.5</sub> by season, age, and sex.

## **002.01.07. Exploration on Explanations for Observed Long-Term Temporal Trend of the Short-Term Association between Fine Particulate Matter Concentration and Hospital Admissions in the U.S.**

Chen Chen

*Chen Chen<sup>1</sup>, Francesca Dominici<sup>2</sup>, Roger Peng<sup>3</sup>, Yun Wang<sup>2</sup>, Jennifer Bobb<sup>4</sup>, Michelle Bell<sup>4</sup>*

*3. Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States.*

*4. Kaiser Permanente Washington Health Research Institute, Seattle, WA, United States.*

**Abstract:** Background In earlier work, we examined whether the PM<sub>2.5</sub>-hospital admissions relative risk varies over time, using hospital admission data of U.S. Medicare beneficiaries and U.S. Environmental Protection Agency PM<sub>2.5</sub> monitoring data. When assuming a linear temporal trend, the change in respiratory hospital admissions per 10 µg/m<sup>3</sup> increase in same day PM<sub>2.5</sub> decreased by 1.77% (95% CI: 0.92 to 2.63%) from the year 1999 to the year 2013, while no statistical significant temporal trend was observed for cardiovascular hospital admissions. To better understand drivers behind the observed temporal trends, this study provides details in our model specifications, as well as exploration on explanations to these observations. Methods To ensure internal validity of the modified Bayesian hierarchical model used, we conducted extensive sensitivity analyses with hypotheses tested stated a priori. Based on previous literatures and biological plausibility, we proposed and evaluated four possible explanations for the decreasing temporal trend for respiratory admissions as well as the lack of temporal trend for cardiovascular admissions: 1) the increase in relative measurement error at lower level of PM<sub>2.5</sub> concentration; 2) flattening of concentration-response function at lower level of PM<sub>2.5</sub> concentration; 3) change in chemical composition of PM<sub>2.5</sub> total mass; 4) change in population susceptibility towards acute exposure to PM<sub>2.5</sub> on respiratory adverse health outcomes. Results and conclusions Based on qualitative evidence, changes in population susceptibility towards acute exposure to PM<sub>2.5</sub> on respiratory adverse health outcomes, and combination of changes in multiple chemical components may partially explain the observed temporal trend. Future research should consider distributed lag model and non-linear concentration response functions, which will require additional exposure data.

## **002.01.08. A National Study of the Mortality Effects of PM2.5 on All-Cause and Cause-Specific Mortality in the Contiguous U.S.**

Helen Tamura-Wicks

*Helen Tamura-Wicks<sup>1</sup>, James Bennett<sup>1</sup>, Matthew Bechle<sup>2</sup>, Robbie M. Parks<sup>1</sup>, C. Arden Pope<sup>3</sup>, Julian Marshall<sup>2</sup>, Rick Burnett<sup>4</sup>, Majid Ezzati<sup>1</sup>*

**Abstract:** Background The adverse health effects of air pollution are established at the individual level, and at the population level in major metropolitan areas. However, the effect on all-cause and cause-specific mortality for the entire country has not been directly evaluated. We investigate the effects of air pollution on mortality for the entire population in the contiguous USA. Methods We used number of deaths for 1999-2011 from the U.S. National Center for Health Statistics (NCHS). Corresponding age-sex-specific population counts were from the US Census Bureau and the NCHS. Annual mean PM2.5 concentrations were estimated by incorporating remotely-sensed and in-situ observations into a land-use regression model. We applied a Bayesian spatiotemporal model to age-sex-county-specific death rates, to estimate the effects of county annual mean PM2.5 concentration on all-cause and cardiopulmonary mortality. The model was formulated to empirically smooth death rates over age and county of residence. We adjusted for poverty, race, income and lung-cancer mortality as a proxy for smoking. Results In unadjusted analysis, all-cause death rates increased by 4.4% (95%CI 3.9-4.9%) for males and 2.5% (95%CI 2.0-3.0%) for females, per 10 $\mu$ g $m^{-3}$  higher PM2.5. Age-specific rate ratios smoothly varied with age, with rate ratios highest in males aged 60-64 years and females 65-69 years. Cardiopulmonary death rates increased by 2.2% (95%CI 1.1 to 3.1%) for males and 0.5% (95%CI -0.4 to 1.4%) for females (all confounders and education). Age-specific proportional effects were largest for males aged 45-49 and females 50-54 per 10 $\mu$ g $m^{-3}$  higher PM2.5. Conclusion In this first direct population-level study for an entire country we found that air pollution increases the risk of deaths from major cause of death.

## **002.01.09. Respiratory and Cardiovascular Diseases Mortality and Long-Term Exposure to Ambient Air Pollution: A 12-Year Cohort Study in Northern China**

Abstract: Cohort evidence linking long-term exposure to ambient air pollution and mortality has come largely from the United States and European countries. There is relatively little evidence from nationally representative cohorts in the high level exposure areas. We aim to investigate the associations between long-term exposures to high level ambient air pollutants and mortality of respiratory and cardiovascular diseases mortality in a cohort of Northern China. A total of 39,054 participants aged 40-89 years were followed from 1998-2009. Annual average concentrations for PM<sub>10</sub>, NO<sub>2</sub>, and SO<sub>2</sub> were determined based on data collected from central monitoring stations. Hazard ratios (HRs) for nonmalignant respiratory, lung cancer mortality and cardiovascular mortality for pollutants were estimated from Cox models adjusting for age at baseline, gender, BMI, education, marital status smoking status, personal incomes, occupation exposure, alcohol consumption and diet habits. Nonmalignant respiratory disease mortality was significantly associated with PM<sub>10</sub> (HR 1.461, 95% CI 1.296-1.648), borderline significant with SO<sub>2</sub> (HR 1.105, 95% CI, 1.022-1.195) in northern China. For each 10µg/m<sup>3</sup> increase in PM<sub>10</sub>, the relative risk ratios (RRs) of all-cause mortality, cardiovascular disease mortality, ischemic heart disease mortality, heart failure disease mortality, and cerebrovascular disease mortality were 1.24 (95% CI, 1.22-1.27), 1.23 (95% CI, 1.19-1.26), 1.37 (95% CI, 1.28-1.47), 1.11(95% CI, 1.05-1.17), and 1.23(95% CI:1.18-1.28), respectively. Each 10mg/m<sup>3</sup> increase in PM<sub>10</sub> concentrations was associated with a 3.4%-6.0% increase in lung cancer mortality in the time-varying exposure model and a 4.0%-13.6% increase in the baseline exposure model. Substantial differences exist in the risk estimates for participants based on assignment method for air pollution exposure. Further research that focuses on exploring dose-response relationship and inter-population comparisons is warranted.

## **O02.01.10. Estimating the Causal Effects of PM2.5 on Life Expectancy**

Joel Schwartz

*Joel D. Schwartz<sup>1</sup>, Yan Wang<sup>1</sup>, Itai Kloog<sup>3</sup>, Maayan Yitshak-Sade<sup>1</sup>, Francesca Dominici<sup>2</sup>, Antonella Zanobetti<sup>1</sup>*

*1. Environmental Health, Harvard University, Boston, MA, United States.*

*2. Biostatistics, Harvard University, Boston, MA, United States.*

*3. Geography and Environmental Development, Ben Gurion University of the Negev, Beersheva, Israel.*

**Abstract:** Background: Many cohort studies have reported associations between PM2.5 and the hazard of dying, but few have used formal causal modeling methods, estimated marginal effects, or directly modeled the loss of life expectancy. Methods: Using all 16,965,154 Medicare beneficiaries in the Northeastern and Mid-Atlantic states (129,341,959 person years of follow-up, 6,334,905 deaths) we fit separate IPW weighted logistic regressions estimating the risk of dying at that age for each year of age, using PM2.5 exposure estimated at the Zip code of residence in that year for each participant. This provides a nonparametric estimate of the distribution of life expectancy as a function of PM2.5. We used Monte Carlo simulations to estimate confidence intervals. Results: The difference in the mean age at death between a counterfactual exposure to 12  $\mu\text{g}/\text{m}^3$  and 7.5  $\mu\text{g}/\text{m}^3$  was 0.85 years (95% CI 0.84, 0.86). The percent of the population that died at or before age 75 was 3.3% higher at 12  $\mu\text{g}/\text{m}^3$ . In comparison, between 2006 and 2015 U.S. life expectancy at age 65 increased by 0.7 years. Conclusions: We believe that this is the first study to directly estimate the effect of PM2.5 on the distribution of age at death using causal modeling techniques to control for confounding. We find that reducing air pollution concentrations below the current U.S. annual standard would substantially increase life expectancy in the Medicare population.

## 002.01C. Methods in Occupational Exposure Assessment

### **002.01.11. Assessing Diesel Particulate Matter Exposure by a Multi-Metric Approach in Three Different Workplaces in Québec (Canada)**

Alan da Silveira Fleck

*Alan da Silveira Fleck<sup>1</sup>, Cyril Catto<sup>1</sup>, Caroline Couture<sup>1</sup>, Maximilien Debia<sup>1</sup>*

*1. Department of Environmental and Occupational Health, Université de Montreal Public Health Research Institute, School of Public Health, Université de Montreal, Montreal, QC, Canada.*

**Abstract:** Elemental carbon and total carbon are the surrogates usually used to assess diesel particulate matter (DPM) exposure, but the measurement of different indicators by direct-reading instruments (DRI) is also described and includes advantages and limitations. The aim of this study was to assess and compare several indicators of DPM exposure in three workplaces by using a multi-metric approach. Three workplaces in Quebec (Canada) were evaluated: An underground mine (W1; n=12), a subway tunnel (W2; n=12) and a truck repair workshop (W3; n=12). Ambient particle number concentration (PNC), submicron particulate matter (PM1), and submicron elemental carbon (EC1-DRI) were measured by DRI. Filter-based samples (FBS) were also collected to estimate the respirable and submicron fractions of elemental carbon (ECR and EC1-FBS), as well as the respirable and submicron fractions of total carbon (TCR and TC1). The geometric means of the DRI were: 128,000; 32,800 and 22,700 particles/cm<sup>3</sup> for PNC in W1, W2 and W3, respectively; 165, 20.4 and 6.9 µg/m<sup>3</sup> for PM1; and 148, 25 and 4.1 µg/m<sup>3</sup> for EC1-DRI. W1 also had the highest concentrations of ECR, EC1-FBS, TCR and TC1. EC1-DRI showed the strongest association with EC1-FBS when considering all workplaces ( $\rho = 0.966$ ;  $p < 0.001$ ), but this association decreased at lower concentrations of DPM. PM1 ( $\rho = 0.936$ ;  $p < 0.001$ ) and PNC ( $\rho = 0.871$ ;  $p < 0.001$ ) also showed a strong positive correlation with EC1-FBS. Ratios of 1.05, 1.76 and 1.30 were calculated between TC1/PM1 for W1, W2 and W3, respectively. This study provided solid information about the concentrations, as well as their associations, of several indicators of DPM exposure in three different exposure contexts.

## **002.01.12. Estimating Personal Exposures with a Multi-Hazard Sensor Network in a Manufacturing Facility**

Christopher Zuidema

*Christopher Zuidema<sup>1</sup>, Larissa Stebounova<sup>2</sup>, Geb Thomas<sup>2</sup>, Thomas Peters<sup>2</sup>, Kirsten Koehler<sup>1</sup>*

*1. Johns Hopkins University, Baltimore, MD, United States.*

*2. University of Iowa, Iowa City, IA, United States.*

**Abstract:** Industrial Hygienists conduct personal sampling to assess if workplaces are in compliance with occupational exposure limits. However, personal sampling is expensive, burdensome to employees, and generally suffers from low sample size. To overcome these shortfalls of personal sampling, we have devised a technique to estimate personal exposure by combining two pieces of data: hazard maps from a wireless sensor network (WSN) and worker location information. The study site was 75,000 m<sup>2</sup> within a heavy-vehicle manufacturing facility where processes included cutting, welding, machining, grinding and abrasive blasting. We developed and deployed a spatially-optimized, 40-node WSN with low-cost sensors for particulate matter (PM; SHARP GP), carbon monoxide (CO; Alphasense CO-B4), oxidizing gases (O<sub>3</sub> + NO<sub>2</sub>; Alphasense OX-B431), and noise (custom sensor) to map hazards inherent in these processes. We generated personal exposure estimates by combining hazard maps with location information recorded by study staff as they simulated workers moving throughout the facility. To make comparisons with personal measurements, study staff also wore direct-reading instruments (DRIs; PM: Thermo pDR-1500; CO: Lascar CO-300 EasyLog; O<sub>3</sub>: 2BTechnologies POM; Noise: Larson-Davis Spark 703+). Three field campaigns produced between 147 and 212 pairs of network-derived estimates and DRI measurements (both 5-min averages) for each hazard. The hazard ranges measured by the DRIs were: 0.110-0.990 mg/m<sup>3</sup> PM, 2-17 ppm CO, 0-57 ppb O<sub>3</sub>, and 71-89 dBA. We observed 59% of PM, 90% of CO, 0% of O<sub>3</sub>, and 100% of noise estimates were within 50% of the DRI measurement. Our WSN built with low-cost sensors was able to map occupational hazards with a high degree of spatial and temporal resolution. Combined with a method to collect location information, we have demonstrated that WSNs can be used to generate personal estimates of occupational exposures that, for some hazards, compare favorably to personal sampling.

## **O02.01.13. The Application of the Spectrosome Approach to the Evaluation of Occupational Co-Exposures to Multiple Chemical Agents**

Delphine Bosson-Rieutort

**Abstract:** The occupational environment represents an important source of exposure to multiple hazards for workers' health. Although it is recognized that mixtures of agents may have different effects on health as compared to single agents, studies continue to focus on individual exposures. The objective was to provide a portrait of occupational co-exposures occurring in the United States, based on the largest multi-industry occupational exposure databank of the Occupational Safety and Health Administration (OSHA). From the Integrated Management Information System (IMIS) of OSHA, measurement data from workplace inspections occurring from 1979 to 2015 were retrieved. The 'workplace situation' (WS) was defined as a job title within a company within a year. Co-exposures were identified by looking at measurements within each WS. To summarize the analyses across all WSs, we used the Spectrosome approach, a new methodology inspired by big data and network science, which relies on the transformation of the data into a network. Among the 346,692 detectable exposure measurements recorded into IMIS, we found 130 690 individual WSs, 30% of which had exposure to at least two agents (up to 39). Among these co-exposures, 5 507 unique combinations of agents were found. The most frequent include co-exposures between metals such as cadmium, lead, iron oxide, manganese, copper, zinc and chromium. However, co-exposures between certain solvents such as acetone, benzene, toluene, and xylene, and also co-exposures between metals and solvents were observed. We also found that metals were associated with dusts and gases, and solvents with styrene and gases. Isocyanates were not found in association with any other class of agents. The spectrosome approach is a powerful data exploration and visualization tool for complex data. This approach enabled quantification and characterization of patterns of co-exposures in the IMIS databank, and revealed frequent occurrences of co-exposures in workplaces in the US.

## **002.01.14. Systematic Evaluation of Bias Associated with a Multiple Imputation Approach for Estimating Missing Exposure Data**

Pamela Dopart

*3. Department of Epidemiology, Johns Hopkins University Bloomberg School of Public Health, Baltimore , MD, United States.*

*4. Department of Environmental Health Sciences, Columbia University Mailman School of Public Health, New York , NY, United States.*

**Abstract:** Introduction: Occupational exposure data frequently include missing or incomplete measurements that, if not addressed, can result in an increased potential for exposure misclassification. Standard approaches for handling missing data, including complete-case analysis and mean substitution, have known limitations. This presents an opportunity to evaluate the use of more advanced statistical approaches, including multiple imputation (MI). Methods: We systematically evaluated a MI approach for addressing missing exposure data using a uniquely large and complete dataset of >1 million radiation measurements collected on workers in the skilled trades at three shipyards from 1975-2005. The original dataset contained no missing exposure information and thus represented the true exposure levels in the population. We performed a series of simulations in which 10-99% of the radiation measurements were randomly replaced with missing values and then imputed. To evaluate the performance of MI, estimates of the mean, median, 25th and 75th percentiles, and variance were calculated for each imputed dataset and compared to the true values of each metric to obtain estimates of the raw and relative bias. Results: For the simulations in which 10-95% of the measurements imputed, the raw bias of the mean ranged from -3.0 to -0.3 (relative bias: 2-15%), the raw bias of the median ranged from -3.0 to 0.0 (relative bias could not be calculated), and the raw bias of the variance ranged from -7.1 to 6.6 (relative bias: 0.1-7.4%). For the simulations in which >95% of the measurements imputed, the magnitude of the biases varied widely for each metric and were not informative. Conclusion: MI was shown to perform well in characterizing the true distribution of exposures, even when large percentages of radiation measurements were imputed. Our results, combined with the statistical advantages of model-based approaches, support the use of MI for addressing missing occupational exposure data.

## **O02.01.15. Assessment of Occupational Exposure to Endocrine Disrupting Agents**

Martie van Tongeren

Abstract: Endocrine disrupting chemicals (EDCs) are exogenous substances that cause adverse health effects through interference with the endocrine system. Exposure to EDC can occur through various pathways, with occupational exposures potentially contributing the highest dose in adults. It has been suggested that we should classify EDCs by biological changes resulting from exposure. EDCs may directly affect the endocrine system via antagonizing and/or mimicking the effect of hormones; disrupting the production, metabolism and transport of hormones or disrupting the production of hormone receptors. For a Canadian study of occupational EDC exposures and the risk of colorectal cancer, we aim to assess occupational exposure to EDCs using the Canadian Job-Exposure Matrix (CANJEM), a newly developed job exposure matrix (JEM) built from expert evaluations of over 30,000 jobs. The CANJEM provides estimates of exposure in specific time periods to a list of 258 agents. In parallel, a crude JEM was developed in the UK by van Tongeren et al (2002) to assess occupational exposure to EDC, which was improved by Brouwers et al in 2008. Based on this EDC-JEM, we have identified and classified 30 CANJEM agents with potential endocrine disrupting effect into five classes: pesticides, polychlorinated organic compounds, phthalate, alkylphenolic compounds and heavy metals. This paper will present a proposed scheme to improve assessment of exposure and risk, by classifying these CANJEM agents according to their potential estrogenic (E), androgenic (A), anti-estrogenic (-E) and anti-androgenic (-A) effects. We will further review the evidence to assess the strength of the endocrine disrupting potential (weak, strong, uncertain). As interest increases in understanding differences in health outcomes between men and women, the availability of an exposure matrix that incorporates some estimate of endocrine disrupting potential will add immeasurably to our understanding of these differences.

## O02.01D. Predicting Indoor Particulate Matter Concentrations

### O02.01.16. Modelling Indoor PM<sub>2.5</sub> and BC in Slum Homes of Mumbai, India

Abhay Anand

*Abhay Anand<sup>1</sup>, Arpan Patra<sup>1</sup>, Harish C. Phuleria<sup>1</sup>*

*1. CESE, IIT Bombay, Mumbai, Maharashtra, India.*

Abstract: Slums which house >50% of the population in Mumbai city (~20 million), are mostly located in the peripheries of major traffic arteries thus facing high risk to air pollution. The objective of this paper is hence to identify the determinants of indoor PM<sub>2.5</sub> and black carbon (BC) in the slum homes and develop predictive indoor models for the same. Multivariate regression models are developed using log-transformed indoor measurements in 40 non-smoking homes and outdoor measurements at a background site in a slum in Mumbai, information on S.E.S. characteristics, building characteristics and activity patterns and publicly available data from central air monitors and geographic information system. Outdoor concentration in the slum is the crucial determinant of both indoor PM<sub>2.5</sub> and BC. Outdoor PM<sub>2.5</sub> is influenced by the proximity to all major roads (especially the internal major roads with congested traffic) whereas BC is influenced by the proximity to the major roads with significant truck traffic. Number of windows and presence of exhaust fan outlets on the wall increased the indoor PM<sub>2.5</sub>, suggesting increased infiltration of outdoor PM<sub>2.5</sub> at higher air exchange rates. Surprisingly, none of the indoor pollutant sources (cooking, incense burning etc.) have a significant impact on 24-hour PM<sub>2.5</sub> or BC. The study demonstrates that the indoor slum PM<sub>2.5</sub> levels could be reasonably estimated (adj R<sup>2</sup>=0.61, RMSE=0.24) using the publicly available ambient monitoring data, GIS based local traffic information, S.E.S. characteristics and home ventilation characteristics. The results show that outdoor pollution remains an important determinant for indoor air pollution in slums. Improving the traffic circulation along the congested inner roads of slum there by reducing local outdoor air pollution and ventilation control in homes during peak traffic hours may be feasible control options.

## **002.01.17. Factors Associated with Airborne Particulate Matter Concentrations in Peri-Urban Guatemala**

John Weinstein

- 2. Centro de Estudios en Salud, Universidad del Valle, Guatemala City, Guatemala.*
- 3. Emory University, Atlanta, GA, United States.*

**Abstract:** Background: Exposure to ambient and household air pollution is the fourth and fifth leading cause of death worldwide and in Guatemala, respectively. In urban Guatemala, over half of households use woodstoves for cooking. Therefore, we explored associations between particulate matter (PM<sub>2.5</sub>) and stove usage in peri-urban Guatemala. Methods: We conducted a cross-sectional study among 60 households using wood and liquid petroleum gas (LPG) stoves. We measured PM<sub>2.5</sub> every 1 minute over a 1-week period using the UCB-PATS photoelectric particle monitor (Berkeley Air) and calculated the proportion of wood versus gas stove usage using iButton temperature sensors (Maxim Integrated) placed on all stoves to log temperature every 5 minutes continuously for 6 months. Results: Lower gas stove usage was associated with elevated kitchen PM<sub>2.5</sub>. Even among exclusive LPG stove households who did not use a woodstove, the median (range) 24-hour PM<sub>2.5</sub> was 71.5 µg/m<sup>3</sup> (65.7-111.9) indicating high ambient air pollution from other sources, such as traffic sources and neighboring homes using woodstoves. Compared to recent stove purchasers, households owning LPG stoves for 1-5 years used the LPG stove less (3.4 hours or 8% of total cooking time), whereas those owning a LPG stove for over 10 years used it 2.2 hours more per week (12% of total cooking time). These differences were associated with parallel trends in PM<sub>2.5</sub> (median (IQR) in µg/m<sup>3</sup>): 125.1 (79.7-186.7) for recent purchasers, 166.2 (85.5-535.5) for gas stoves owned 1-5 years and 101.8 (85.1-191.7) for gas stoves owned >10 years. Conclusions: Even with exclusive gas stove use, PM<sub>2.5</sub> remained well above WHO guidelines (annual mean concentration 35µg/m<sup>3</sup>) set to protect human health. Thus, there is a need for national and local efforts to reduce air pollution from both cooking and non-cooking sources. Additionally, as gas stoves were used least among those owning it 1-5 years, this may signal a critical time to avoid stove dis-adoption.

## **O02.01.18. Global Estimation of Exposure to PM2.5 from Household Air Pollution**

Matthew Shupler

*Matthew Shupler<sup>1</sup>, William Godwin<sup>2</sup>, Joseph Frostad<sup>2</sup>, Kalpana Balakrishnan<sup>6</sup>, Paul Gustafson<sup>5</sup>, Santu Ghosh<sup>4</sup>, Raph Arku<sup>3</sup>, Michael Brauer<sup>1</sup>*

- 6. Sri Ramachandra University, Chennai, India.*

**Abstract:** Background: Household air pollution (HAP) exposure from cooking with dirty fuels is a major global health risk factor. Epidemiological studies have demonstrated significant variation in particulate matter concentrations of diameter  $\leq 2.5$  micrometers (PM2.5), an important metric for using integrated exposure-response functions to assess risks. To characterize global HAP-PM2.5 exposures, novel estimation methods are needed, as financial/resource constraints render it difficult to monitor exposures in all relevant areas. Methods: A Bayesian, hierarchical HAP-PM2.5 global exposure model was developed using kitchen and female HAP-PM2.5 exposure data available in published, peer-reviewed studies. Cooking environment characteristics and quantitative HAP-PM2.5 measurements from 47 studies were used to model urban and rural, fuel- and country-specific (traditional wood, improved biomass, coal, dung and gas/electric stoves) 24-hour HAP-PM2.5 kitchen concentrations and male, female and child exposures for 106 countries in Asia, Africa and Latin America. Results: A model incorporating fuel/stove type, urban/rural location and the socio-demographic index resulted in a Bayesian R<sup>2</sup> of 0.57. Estimated global average 24-hour HAP-PM2.5 concentrations in rural kitchens using traditional, improved biomass, animal dung, and coal stoves were 320  $\mu\text{g}/\text{m}^3$ , 180  $\mu\text{g}/\text{m}^3$ , 1,760  $\mu\text{g}/\text{m}^3$  and 400  $\mu\text{g}/\text{m}^3$ , respectively, higher than in rural kitchens using gas/electricity. Modeled female exposures from traditional wood stoves varied from 90-260 across countries, on average, with urban area exposures 40  $\mu\text{g}/\text{m}^3$  less than those in rural areas. Male and child rural area exposures from traditional wood stoves ranged from 60-190 and 80-230  $\mu\text{g}/\text{m}^3$ , respectively; urban area exposures were 10  $\mu\text{g}/\text{m}^3$  less than rural area exposures, among both sub-groups. Conclusions: A global exposure model incorporating type of fuel-stove combinations adds specificity and reduces exposure misclassification for estimation of HAP risk.

## **002.01.19. Predicting Indoor Fine Particulate Matter in the Apartments of Pregnant Women in Ulaanbaatar, Mongolia**

**Abstract:** Background: Indoor and outdoor exposures to fine particulate matter (PM<sub>2.5</sub>) are both leading risk factors for death and disease, but collecting indoor measurements is often infeasible for large study populations. Methods: We developed models to predict indoor PM<sub>2.5</sub> concentrations for pregnant women who were part of a randomized controlled trial of portable HEPA filter air cleaners in Ulaanbaatar, Mongolia. We used multiple linear regression (MLR) and random forest regression (RFR) to model indoor PM<sub>2.5</sub> concentrations with 447 independent 7-day PM<sub>2.5</sub> measurements and 87 potential predictor variables obtained from outdoor monitoring data, questionnaires, home assessments, and geographic data sets. Models were evaluated in a 10-fold cross-validation. Results: The predictors in the MLR model were season, outdoor PM<sub>2.5</sub> concentration, the number of air cleaners deployed, and the density of gers (traditional felt-lined yurts) surrounding the apartments. The RFR had a higher model-based R<sup>2</sup> (93.8%) than the MLR model (52.4%), but both models had similar performance in cross-validation (R<sup>2</sup> = 48.9% for RFR vs. 50.2% for MLR). Intervention status alone explained only 6.0% of the variation in indoor PM<sub>2.5</sub> concentrations. Conclusions: We predicted a moderate amount of variation in indoor PM<sub>2.5</sub> concentrations using easily obtained predictor variables and the models explained substantially more variation than intervention status alone. While RFR shows promise for modeling indoor concentrations, our results highlight the importance of out-of-sample validation when evaluating model performance.

## **O02.01.20. Leveraging Real-Time Data to Identify Determinants of Indoor PM2.5 Exposure Disparities at the Community-Level**

MyDzung Chu

*MyDzung T. Chu<sup>1</sup>, Sara Gillooly<sup>1</sup>, Jose Vallarino<sup>1</sup>, Lacy Reyna<sup>1</sup>, Gary Adamkiewicz<sup>1</sup>*

**Abstract:** Elucidating determinants of increased indoor exposures is critical to alleviating exposure and health disparities. PM2.5 is a key determinant of indoor air quality and cardiorespiratory health. As part of the Center for Research on Environmental & Social Stressors in Housing across the Life Course (CRESSH), we investigated indoor PM2.5 sources within small spatial and temporal scales. We recruited 72 households in Chelsea, MA from 6/2016-8/2017. We collected in-home and outdoor PM2.5, housing, and activity data across 1 week for 2 seasons using a real-time sensor platform, visual assessments, and surveys. We assessed predictors of indoor PM2.5 by season using linear mixed-effect models accounting for non-linear effects of time and outdoor PM2.5, race/ethnicity, rent status, housing type, occupancy, and kitchen vent use. Households were predominantly Hispanic/Latino (49%), renters (54%), & low-income (<\$50K) (54%). Mean indoor PM2.5 was 10.3 $\mu\text{g}/\text{m}^3$  (SD: 60.2) for summer and 9.6 $\mu\text{g}/\text{m}^3$  (30.2) for winter. Across seasons, significant predictors were time of day ( $\beta=1.16-2.18$ ,  $p<0.01$ ) & outdoor PM2.5, which was more strongly associated in summer ( $\beta\geq 1.43$ ,  $p<0.02$ ). In summer, use of gas stoves (vs. electric) ( $\beta=2.05$ ) & having visitors who smoked ( $\beta=4.55$ ) were also significant ( $p<0.04$ ). In winter, any weekend cooking ( $\beta\geq 3.23$ ), residential smoking ( $\beta=2.72$ ), & weekday status ( $\beta=1.07$ ) were also significant ( $p<0.02$ ). Risk factors varied socio-demographically: renters were more likely to smoke (8.5x), homeowners more often had gas stoves (1.3x), & low-income households cooked longer periods ( $\geq 60$  min.: 1.72x). Our findings underscore the value of real-time data to identify time-varying sources and contributors of indoor PM2.5. Seasonal effects are likely driven by changes in meteorology, housing conditions, and activity that affect air exchange. The socioeconomic patterning of risk factors, much of which is modifiable, implicate targets for reducing exposure and health disparities.

## O02.01E. Understanding Early Life Exposures and Nutritional Health through the Exposome

**Abstract:** Background: The exposome encompasses the totality of environmental exposures from conception onwards. The Human Early Life Exposome (HELIX) project offers a unique opportunity to explore the interplay between the early-life exposome and the molecular responses in childhood. Method: HELIX consists of 1,300 children aged 6-11 years from 6 European cohorts (BIB in UK, EDEN in France, KANC in Lithuania, INMA in Spain, MOBA in Norway, and RHEA in Greece). The child's prenatal and early life exposome included >200 variables: Air pollution, build environment, noise, cotinine, metals, POPs, PFAS, phthalates, phenols, and organophosphates, and life-style factors (socio-economic capital, diet and physical activity). Cross-sectional molecular measurements were obtained, including blood DNA methylation, gene and miRNA transcription, serum and urinary metabolites and plasma proteins. The exposome was related to the molecular marks through linear regression models. Results: During the prenatal period, exposure to tobacco (maternal active smoking, urinary cotinine and cadmium) was associated with DNA methylation at age 6-11 years. Moreover, maternal levels of essential metals and elements (i.e. zinc) were also associated with DNA methylation. During the postnatal period, child PFAS, mercury, arsenic and selenium were associated with metabolites derived from fish intake (i.e. polyunsaturated fatty acids (PUFA)); and child organophosphate pesticides were associated with urine metabolites related to fruit consumption (i.e. proline betaine). Further associations were found with copper and persistent pollutants across several omics suggesting a link to systemic inflammation and adiposity. Conclusion: While main associations of the prenatal exposome were with childhood DNA methylation, cross-sectional exposures were more related to metabolic profiles and proteins. Molecular biomarkers informed about source of exposure (i.e. fish) and about molecular mechanisms (i.e. inflammation).

**Abstract:** Background: High cholesterol levels during childhood have been associated with increased risk of atherosclerosis later in life. Apart from traditional risk factors for dyslipidemia, such as high fat diet and obesity, the contribution of environmental exposures on variations in lipid levels in childhood, is unclear. Aim: To assess the impact of a wide array of environmental exposures during pregnancy and childhood on lipid profiles in children using an exposome-wide approach. Methods: Within the HELIX exposome project, we measured over 90 prenatal and 110 childhood environmental exposures in 1,301 mother-child pairs from 6 European countries. We also measured in 2-hour fasting plasma samples, total (TC), high-density (HDL), low-density (LDL) lipoprotein cholesterol, and triglyceride (TG) levels at the age of 6-11 years. Associations were assessed using agnostic exposome-wide analyses (ExWAS) correcting for multiple comparisons. Results: Childhood exposure to organochlorine compounds was associated with increased lipids. Exposure to hexachlorobenzene (HCB) was associated with higher TC, LDL and TG levels (mean change per IQR increase: 6.6 mg/dL, 95% CI: 4.4 to 8.8; 5.7 mg/dL, 95% CI: 3.6 to 7.8 and 6.0 mg/dl, 95% CI: 2.6 to 9.4 respectively) after multiple testing correction. Dichlorodiphenyltrichloroethane (DDT) and polychlorinated biphenyls (PCBs) childhood levels were also associated with increased TGs (6.9 mg/dl, 95% CI: 3.4 to 10.4 and 9.6 mg/dl, 95% CI: 5.4 to 13.9 respectively). Childhood exposure to polybrominated diphenyl ether (PBDE 153) was associated with a 5.2 mg/dL change in TC (95% CI: 2.6 to 7.8), while copper exposure was associated with a -1.7 mg/dL change in HDL (95% CI: -2.7 to -0.8) and a 3.3 mg/dL change in LDL (95% CI: 1.5 to 5.1). Conclusions: Children with higher exposure to organochlorine compounds and copper had higher levels of lipids. Further work is needed to examine the underlying mechanisms and to exclude the role of reverse causation.

## **O02.01.23. An Exposome-Based Approach to Environmental and Nutritional Impacts of Food on Human Health**

Olivier Jolliet

*Katerina Stylianou<sup>1</sup>, Vy K. Nguyen<sup>1</sup>, Victor L. Fulgoni III<sup>2</sup>, Olivier Jolliet<sup>1</sup>*

*1. University of Michigan, Ann Arbor, MI, United States.*

*2. Nutrition Impact, LLC, Battle Creek, MI, United States.*

**Abstract:** Development of sustainable products requires comparing direct impacts on the user and indirect impacts such as environmental pollution in a consistent exposome-based approach. We currently lack tools that can comparably quantify environmental impacts and nutritional health effects at the food level. Here, we evaluate and compare impacts associated with foods, accounting for nutrition, particulate matter (PM) from food production, and chemical migration from food packaging. We test this approach on a pizza case study. We quantify the Dietary Risk Factors (DRF) as the disease, gender and age-specific health burden attributable to a g of 15 risk components identified to pose risk on health according to the Global Burden of Diseases, expressed in disability adjusted life years (DALYs/g). We multiply DRFs with the corresponding component densities (grisk/servingfood) for 6000+ foods, to yield the Health Nutritional Index (HENI) measured in DALYs per serving. We evaluate in parallel exposures (intake fractions) associated with ammonia emissions during food production and chemicals migrating from food packaging and use dose-responses and severity factors to evaluate their impacts in DALYs. DRFs range from -57  $\mu$ DALY/gomega-3 to 8  $\mu$ DALY/g sodium, with ischemic heart disease dominating the burden associated with most risks. HENI scores for 68 pizzas range from -3 to 36  $\mu$ DALY/serving (median: 17  $\mu$ DALY/serving), with meat pizzas having the highest impacts and vegetarian or fruit pizzas the lowest. The corresponding PM impacts are substantially lower with a median of 0.15  $\mu$ DALY/serving. Environmental impacts are strongly correlated with nutritional impacts, signifying that unhealthy foods also have the highest environmental impacts and vice-versa ( $r_{CO2}=0.69$ ,  $r_{PM2.5}=0.77$ ). For food contact material, the product intake fraction (PiF) typically ranges from  $1E-4$  to 0.8 and when combined with effect data it can yield impact estimates in  $\mu$ DALY/serving.

## 002.01.24. Environmental Exposures and Childhood Obesity: An Exposome Analysis

Martine Vrijheid

*Martine Vrijheid<sup>1</sup>, Serena Fossati<sup>1</sup>, Lea Maitre<sup>1</sup>, Regina Grazuleviciene<sup>2</sup>, Mark Nieuwenhuijsen<sup>1</sup>, Theano Roumeliotaki<sup>3</sup>, Remy Slama<sup>4</sup>, Cathrine Thomsen<sup>5</sup>, Marina Vafeiadi<sup>3</sup>, Charline Warembourg<sup>1</sup>, John Wright<sup>6</sup>, Xavier Basagaña<sup>1</sup>, Leda Chatzi<sup>3</sup>*

1. ISGlobal, Barcelona, Barcelona, Spain.
2. Vytautas Magnus University, Kaunas, Lithuania.
3. University of Crete, Heraklion, Greece.
4. INSERM, Grenoble, France.
5. NIPH, Oslo, Norway.
6. Bradford Teaching Hospitals NHS Foundation Trust, Bradford, United Kingdom.

**Abstract:** Background With an increasing number of suspected developmental obesogens, there is a need to identify those most relevant for childhood obesity risk. Objective To systematically test associations between many environmental exposures and obesity and adiposity in children, using an exposome approach. Methods The HELIX study measured obesity outcomes in 1,301 children from 6 European countries, aged 6-11 years, including age-and-sex specific SD-scores for body mass index (zBMI), waist circumference, skinfold thickness, and body fat mass. HELIX estimated over 90 prenatal and over 110 childhood environmental exposures to outdoor, chemical and lifestyle factors. Exposome-outcome associations were tested using agnostic exposure-wide analyses (ExWAS) and with the deletion-substitution-addition (DSA) algorithm that considers all exposures simultaneously. Results For prenatal exposures, maternal smoking-related variables (active and passive smoking, cotinine and cadmium concentrations) were associated with higher child zBMI in the ExWAS, although these associations did not pass the multiple testing corrected p-value (0.001). Maternal passive and active smoking during pregnancy were also selected in the DSA model. For childhood exposures, 18 exposures were associated with zBMI in the ExWAS after multiple testing correction ( $p < 0.0006$ ). In the DSA model, exposure to indoor particulate matter and copper were associated with increased zBMI, and HCB and PBDE-153 with decreased zBMI. Other adiposity outcomes showed similar results. Conclusions Early life exposure to several pollutants is associated with childhood obesity, with smoking and indoor air pollutants raising particular concern. Results for childhood exposures may suffer from reverse causation bias. The exposome's systematic approach can be used to prioritize factors for further investigation and intervention, and avoids problems of selective reporting, co-exposure confounding, and false positive results.

## **O02.01.25. Ethical Considerations Related to Studies of the Exposome**

Susan Pinney

*Susan M. Pinney<sup>1</sup>*

*1. Dept of Environmental Health, U of Cincinnati College of Medicine, Cincinnati, OH, United States.*

Abstract: The exposome encompasses the totality of human environmental exposures from conception onwards, complementing the genome. The concept was first proposed in 2005 by Christopher Wild in an article entitled "Complementing the genome with an 'exposome': The outstanding challenge of environmental exposure measurement in molecular epidemiology". The idea of the exposome was first proposed during a time of great attention to the genome, and refocused attention on environmental exposure data for casual research. In studying the exposome, there are both technical and ethical challenges. What is the current state of research methods for studying the exposome? What is our level of precision in characterizing the exposome (beneficence - maximize possible benefits and minimize possible harms)? Have these methods been validated? Are there ways to assess whether statistical methods for studying exposure mixtures yield valid results? Do we have sufficient confidence in the methods to communicate the results to the general public (beneficence)? With very complex analytical methods, and considering multiple environmental and lifestyle risk factors simultaneously, how do we communicate risk to the general public (comprehension - present the information at the study subject's level of understanding)? When returning individual exposure information (from environmental sampling or biomarkers), how many exposures are reasonable to include (respect for autonomy)? Among participants who were minor children at the time the data and biospecimens were collected and are now adults, should they be consented as adults before receiving individual exposure information? What level of responsibility does the environmental epidemiologist have to move research findings into public health action? And how?

## S02.01A. Challenges of Assessing Non-Tailpipe Emissions for Urban Air Quality and Health

### S02.01.01. Dust in the Wind: The Changing Nature of Traffic-Related Air Pollution

Greg Evans

*3. Ontario Ministry of the Environment and Climate Change, Toronto, ON, Canada.*

Abstract: Traffic has a substantial impact on air pollution in many cities. As the introduction of new vehicle technologies reduces emissions of some pollutants, the role of non-tailpipe emissions is increasing in prominence. The impact of non-tailpipe emissions has been investigated using 18 months of data collected at two near road monitoring sites in Toronto, one beside a downtown arterial road and the other beside highway 401 within the busiest stretch of highway in North America. These data indicate that non-tailpipe emissions can have large impacts on the concentrations of selected metals. Hourly and 24-h integrated measurements have revealed diurnal, weekday/weekend, seasonal and meteorology dependent patterns that help to isolate traffic-related metal sources and provide insight into the relative importance of direct emissions and resuspension of road dust. Positive matrix factorization has been applied to isolate traffic-related factors and the contribution of non-tailpipe emissions to ambient PM<sub>2.5</sub>. The oxidative potential and metal concentrations in dust samples collected at sites across Toronto are being used to evaluate the relative hazard posed by these vehicle emissions. Overall, this talk will summarize what is known about the sources, composition, and size of the different non-tailpipe particulate emission components and highlight markers of these sources that can be used for future source apportionment and modeling efforts.

## **S02.01.02. Toxicity of Non-Tailpipe Emission**

Miriam Gerlofs-Nijland

*Miriam Gerlofs-Nijland<sup>1</sup>*

*1. National Institute for Public Health and the Environment (RIVM), Bilthoven, Netherlands.*

Abstract: There is substantial evidence that exposure to airborne particulate matter (PM) from road traffic is associated with adverse health outcomes. Therefore, many efforts have been taken to diminish traffic emissions, which have resulted in a considerable reduction of tailpipe emissions in the last decades. Although it is often assumed that negative health effects are to be caused by tailpipe emissions such as soot, other components may also contribute to detrimental effects. PM from traffic emissions is not only derived from engine combustion but consist of wear emission from the road, tires and brakes as well. The contribution of these non-exhaust emissions to PM concentrations in cities is comparable or might even be more than the tailpipe contribution. With reducing tailpipe emissions, the relative contribution of non-tailpipe emissions to particulates is increasing although the implications for health are mainly unknown. This symposium presentation will give an overview of the reported toxicity studies on non-exhaust including the possible mechanisms by which non-tailpipe emissions may exert adverse health effects, for example via the link with oxidative potential.

### **S02.01.03. Modeling Brake and Tire Wear Emissions in Regulatory Models in the United States**

Darrell Sonntag

*Darrell Sonntag<sup>1</sup>, Chad Bailey<sup>1</sup>, Richard Baldauf<sup>1</sup>, Christina Parsons<sup>1</sup>, Chris Owen<sup>1</sup>, Alison Eyth<sup>1</sup>, Sonya Collier<sup>2</sup>, Sam Pournazeri<sup>2</sup>, Seungju Yoon<sup>2</sup>*

- 1. US Environmental Protection Agency, Ann Arbor, MI, United States.*
- 2. California Air Resources Board, Sacramento, CA, United States.*

Abstract: MOVES and EMFAC (for California only) are the regulatory vehicle emission models used in the United States to estimate brake and tire wear emissions. The emissions estimates are then used in conjunction with air dispersion models (including AERMOD, US EPA's preferred dispersion model) to estimate PM<sub>2.5</sub> and PM<sub>10</sub> concentrations in the near-road environment. We will provide an overview of the data and methods that MOVES and EMFAC uses to estimate brake and tire emissions, including a comparison to exhaust particulate matter emissions. For example, MOVES does not account for the important differences in chemical speciation between brake, tire and exhaust particulate matter emissions. We will discuss current efforts to evaluate and improve the brake and tire emission rates in the models. We will also provide an overview of regulatory context in which the emission and air quality modeling tools are used, and the limitations of these tools for conducting exposure and epidemiology studies.

#### **S02.01.04. Characterization of Non-Tailpipe and Tailpipe Emissions in Boston: Road Work in Progress**

Joy Lawrence

*Joy Lawrence<sup>1</sup>, Petros Koutrakis<sup>1</sup>, Brent A. Coull<sup>2</sup>, Marco Martins<sup>1</sup>*

*1. Environmental Health, Harvard TH Chan School of Public Health, Boston, MA, United States.*

*2. Biostatistics, Harvard TH Chan School of Public Health, Boston, MA, United States.*

**Abstract:** Background: The design and preliminary results of a study designed to develop tools to improve assessment of exposure to traffic particles and pollutants for health effects studies, characterize direct (tailpipe and non-tailpipe) and indirect contributions, and identify parameters which influence them. Study Design: Using a mobile sampling platform equipped with coarse and fine particle matter (PM) concentrators we collect ambient ultrafine, accumulation mode and coarse particle samples near roads in the Greater Boston. We also collect PM<sub>2.5</sub> and PM<sub>10</sub> aerosolized surface road dust in situ. We collect these samples at three distance ranges (roadside, 0-50m; intermediate, 50-150m; background, 500-1000m) from 100 (Census Feature Class Code A1, A2, or busy A3 type) road sites included in this study. Sites are selected based on factors including traffic density/composition, speed limit, road conditions, traffic lights, nearby development type. Each day of sampling, we also collect continuous particle count, mass, traffic, and weather data at all 3 locations simultaneously, to assess temporal variability at sites. A subset of sites will be visited multiple times in different seasons. Preliminary Results: We have completed a small number of sites and observe enrichment factor for fine particles between 8.8 and 10.8 times ambient and the coarse particle enrichment between 74 and 91. So far, enrichment has been higher at the Roadside than background or intermediate sites. All filters had loading sufficient for XRF and EC/OC analysis. Preliminary results from road dust samples with elemental concentrations normalized to Aluminum suggest trends in both coarse and fine composition with distance from road across sites. For example, fine road dust decreases relative to Al with distance from the road for Cu, Zn, Ti, Cr, Mn, and Fe, while coarse road dust suggests similar trends for Ca, Mn, Zn, and Ti.

## **S02.01.05. Health Effects of Exposure to Non-Tailpipe PM Emissions: A Critical Review**

Gerard Hoek

*Gerard Hoek<sup>1</sup>*

*1. IRAS, University Utrecht, Utrecht, Netherlands.*

**Abstract:** Gerard Hoek **Background:** Because of the reduction of tailpipe particulate emissions in most-high income countries, the relative importance of non-tailpipe emissions of motor vehicles is increasing. Epidemiological studies have started to study non-tailpipe emissions specifically. In this presentation, I will review epidemiological studies that have specifically assessed non-tailpipe emissions, separate from exhaust emissions. **Methods:** Epidemiological studies were identified by a search in Medline. Studies assessing mortality and morbidity endpoints were eligible. We included time series, case-crossover assessing short-term effects and cohort studies assessing long-term exposures. **Results:** We identified a fairly large number of time series studies on measured elemental composition and mortality / hospital admissions, predominantly in the USA. A small number of (birth and adult) cohort studies was identified where exposure was assessed with land use regression of elemental composition, including the European ESCAPE study. In some studies, Cu, Fe or Zn in PM were associated with adverse health effects, but in other studies no association was found. In most studies that evaluated markers of tailpipe emissions such as NO<sub>2</sub> or Black carbon, the correlation with these markers was high. **Conclusions:** Epidemiological studies on short and long term exposure to non-tailpipe emissions have generally not been fully consistent. Reasons for inconsistencies across studies included limitations in exposure assessment and the challenge of separating non-tailpipe from tailpipe emissions effects.

## S02.01B. Contaminant Exposures in Indigenous Communities: Tribal Research Avenues and Health Effects

### **S02.01.06. Contaminant Exposures in Indigenous Populations: A Road to Understanding**

Judith Zelikoff

*Judith T. Zelikoff<sup>1</sup>, Vincent Mann<sup>2</sup>, Krina Shah<sup>1</sup>*

*1. Environmental medicine, NYU School of Medicine, Tuxedo, NY, United States.*

*2. Ramapough Lenape Tribal Nation, Ringwood, NJ, United States.*

Abstract: This introductory presentation will consider the overall toxicological perspective of growing up as a Native American person in a contaminated world. Of a total of 1,388 Superfund sites throughout the nation, nearly 25 percent of them are in Indian country. Fourteen percent of all Native Americans live within 3-mi of a Superfund site. Given their cultural traditions of hunting, fishing and growing their own food, Native Americans are at greater risk for contaminant exposure through a variety of pathways. Many of these sites are not cleaned up, though not all of those listed are still active. In cases like the Navajo, the Akwesasne Mohawk and the Quapaw Tribe, the human health impacts are known because some health professionals and scientists took enough interest to do studies in their regions. But, this knowledge is the exception rather than the rule. Many of the health impacts associated with living, working and/or playing in these areas persist through generations, as in the case of the Mohawk, as a result of exposure to endocrine disrupting chemicals. This presentation will provide a description of where we are now employing a specific example of the urban-dwelling Ramapough Lenape Tribe as presented by Ramapough Turtle Clan Chief, Vincent Mann. There is an urgent need to form trusted partnerships and community-driven Tribal health studies that can build community capacity and reduce potential contaminant exposures to an already vulnerable population. A mutual community academic perspective on how to move forward and success stories with the Ramapough, will close the presentation

## **S02.01.07. Contaminant Exposures in Indigenous Communities: Tribal Research Avenues and Health Effects**

**Abstract:** Intro American Indians were stripped of traditional tobacco upon first contact with settlers, forcing them to use commercial tobacco for sacred ceremonies. Colonization and exploitation of American Indians by tobacco companies contribute to the Cheyenne River Sioux Tribe's (CRST) 51% smoking rate. Methods To reduce secondhand smoke exposure in indoor public places on CRST, the Canli Coalition began advocating for a tribal smoke-free air law in 2009. By 2012, 76% of tribal members supported smoke-free air in public. In 2015, the CRST became the third tribe in America to pass a comprehensive smoke-free air policy. Evidence supporting such policies will pave the way for more smoke-free policies in Indigenous territories. The CRST Mercury in the Water Study sought to find exposures to metals through fishing, smoking and land use pathways. Commercial tobacco contributes to heavy metal exposure and poor health outcomes through metal toxicants. Tobacco use and secondhand smoke exposure was collected using a survey and cotinine levels confirmed nicotine exposure. 225 adult CRST members participated from 2014-2016 (75 per year). This analysis focuses on tobacco exposure changes after the 2015 CRST Ordinance 77 was passed. Results The year following Ordinance 77, the rate of smokers with high cotinine levels (> 15 ng/ml serum cotinine concentration) was reduced from 83% to 40%. Non-smokers with high cotinine levels reduced from 18% to 13% in the year following policy adoption. The number of cigarettes smoked among current smokers did not change significantly. However, participants with intermediate cotinine levels increased in 2016 for smokers and non-smokers. Detailed home and indoor sampling for nicotine surface deposition and toxicant exposure can be included in future Tribal research agendas to accurately depict the impact of smoke-free air policies in Indigenous communities.

## **S02.01.08. Cadmium and Mercury Exposure among Dene/Métis Communities of the Northwest Territories, Canada**

Brian Laird

*Mylene Ratelle<sup>1</sup>, Leicester Fung<sup>1</sup>, Matthew Laird<sup>1</sup>, Brian Laird<sup>1</sup>*

*1. University of Waterloo, Waterloo, ON, Canada.*

Abstract: In northern Indigenous communities, eating traditional foods (which include locally harvested wild game, fish, game birds, and plants) is associated with improved nutritional status. However, traditional foods can occasionally increase human exposures to contaminants. To mitigate potential risks from elevated contaminant levels in fish and wildlife, public health officials regularly respond to the results from environmental monitoring programs by designing notices that advise individuals to limit their consumption of particular traditional foods. For example, elevated mercury (Hg) levels in Walleye, Northern Pike, and Lake Trout in some subarctic lakes led to the release of a series of consumption notices by the Government of the Northwest Territories Department of Health and Social Services. Also, high levels of cadmium (Cd) in the organs of moose from the Southern Mackenzie Mountains, Canada resulted in consumption notices recommending people to limit their consumption of kidney and liver of moose harvested from this region. Since 2016, a community-based human biomonitoring project has been run in nine Dene/Métis communities of the Dehcho and Sahtú regions of the Northwest Territories Mackenzie Valley (n=538). This project included dietary assessments (e.g., 24-hour Recall, Food Frequency Questionnaire) as well as hair, urine and blood sampling to characterize contaminant exposures among participants. Although Hg and Cd levels in traditional foods from the Northwest Territories are occasionally elevated, the results from this biomonitoring research show exposures to these metals to be generally similar to those observed in other populations in Canada. These results are supporting ongoing efforts at the community and territorial level to design follow up plans in response to environmental monitoring data.

## **S02.01.09. Mercury and Other Toxicants from Mine Waste and Immune System Health Effects: The Cheyenne River Sioux Tribe's Concerns**

Esther Erdei

*Marcia O'Leary<sup>2</sup>, Esther Erdei<sup>1</sup>*

*1. Community Environmental Health Program, University of New Mexico, Albuquerque, NM, United States.*

*2. Missouri Breaks Industries Research Inc., Eagle Butte, SD, United States.*

Abstract: Over 900 silver and gold mines were in operation in the Black Hills area of South Dakota for almost 100 years. Extraction released mercury to the environment and it is up-taken by various fresh water fish. Fishing is vital part of Lakota life that supports subsistence and provides recreation along the Cheyenne River. CRST communities sought academic partnership as early as 2000 trying to address concerns of immunotoxicity associated with metals originated from the drinking water. Our team recruited 225 adults (53% males, 47% females; mean age: 42.9 years (range: 18-77 yrs) regularly fish along CRST waters. Hg considered ubiquitous on the land and arsenic exposures were also estimated via fishing survey. Smoking and various land use activities were assessed using questionnaires. Blood and urine samples were collected for biomonitoring. Indirect immunofluorescence and in-house ELISA techniques were used for serum autoimmunity marker determinations and multiplexing assays were applied to determine serum cytokines and immunoglobulins, components of the human immune response. Percentages of blood lymphocytes were also measured by flow cytometry. Serum cotinine concentrations validated self-reported smoking. Multivariate statistical modeling ascertained that current cigarette smoking and fish consumption were significant predictor variables of increased cytokine productions resulting in an activation of cellular and mucosal immune reactivity (GM-CSF,  $p=0.015$ ; IL-2,  $p=0.008$ ; IL-8,  $p=0.049$ ). Increased prevalence of antinuclear autoimmunity (36% ANA positivity, score >2+) was identified compared to the US national average (13.8%) and showed negative associations with serum cotinine concentrations. These results suggest that environmental toxicants can have complex, both pro- and anti-inflammatory influence. Immune response inhibition via toxicant exposures might play crucial role in chronic disease development in exposed Indigenous communities.

**S02.01.10. The Namaus (All Things Fish) Project: Community-Engaged Environmental Health Research in Collaboration with the Narragansett Tribe in Charlestown, RI, U.S.A.**

Marcella Thompson

*Marcella R. Thompson<sup>1</sup>*

*1. College of Nursing, University of Rhode Island, Providence, RI, United States.*

Abstract: For scientific knowledge to be useful, it has to be translated, synthesized, exchanged and applied within specific social, institutional and human constructs. There is none more challenging for non-Indigenous researchers than translating research to practice and policy within the context of an Indigenous knowledge framework. The Namaus (All Things Fish) Project team ensures the integration of scientific knowledge with the cultural knowledge of the Narragansett tribal community by nurturing a long-term mutually beneficial partnership based on trust and mutual respect. Conducting community-engaged environmental health research and incorporating community-based activities builds the capacity of the Narragansett Tribal government and its members for informed decision-making and participation in Tribal environmental health policy and regulatory formulation.

S02.01C. Critical Exposure Windows, Selection Biases and Novel Methods:  
Methodological Complexities in Reproductive Environmental Epidemiology

**S02.01.11. Potential for Bias when Estimating Critical Windows for Air Pollution in Children's Health**

Ander Wilson

**Abstract:** Evidence supports an association between maternal exposure to air pollution during pregnancy and children's health outcomes. Recent interest has focused on identifying critical windows of vulnerability. An analysis based on a distributed lag model (DLM) can yield estimates of a critical window that are different from those from an analysis that regresses the outcome on each of the 3 trimester-average exposures (TAEs). Using a simulation study, we assessed bias in estimates of critical windows obtained using 3 regression approaches: 1) 3 separate models to estimate the association with each of the 3 TAEs; 2) a single model to jointly estimate the association between the outcome and all 3 TAEs; and 3) a DLM. We used weekly fine-particulate-matter exposure data for 238 births in a birth cohort in and around Boston, Massachusetts, and a simulated outcome and time-varying exposure effect. Estimates using separate models for each TAE were biased and identified incorrect windows. This bias arose from seasonal trends in particulate matter that induced correlation between TAEs. Including all TAEs in a single model reduced bias. DLM produced unbiased estimates and added flexibility to identify windows. Analysis of body mass index z score and fat mass in the same cohort highlighted inconsistent estimates from the 3 methods.

## **S02.01.12. Bias from Conditioning on Live Birth in Pregnancy Cohorts: An Illustration Based on Neurodevelopment in Children after Prenatal Exposure to Organic Pollutants**

Zeyan Liew

*Zeyan Liew<sup>1</sup>, Jørn Olsen<sup>2</sup>, Beate Ritz<sup>1</sup>, Onyebuchi Arah<sup>1</sup>*

*2. Department of Clinical Epidemiology, Aarhus University, Aarhus, Denmark.*

Abstract: Only 60-70% of fertilized eggs may result in a live birth and very early fetal loss mainly goes unnoticed. Outcomes that can only be ascertained in live born children will be missing for those who do not survive till birth. We illustrated a common bias structure (leading to 'live-birth bias') that arises from studying the effects of prenatal exposure to environmental factors on long-term health outcomes among live births only in pregnancy cohorts. We used prenatal exposure to perfluoroalkyl substances (PFAS) and the risk of attention-deficit/hyperactivity disorder (ADHD) in school-aged children as an example. PFAS are persistent organic pollutants that may impact human fecundity and be toxic for neurodevelopment. We simulated several scenarios based on characteristics from the Danish National Birth Cohort (DNBC), and we found that a weak inverse-association may appear even if PFAS do not cause ADHD but have a considerable effect on fetal survival. Our example highlights the need for knowing the determinants of pregnancy loss and the importance of quantifying bias arising from conditioning on live birth in observational studies.

### **S02.01.13. Live Birth Bias May Affect Associations between Air Pollution and Autism**

Raanan Raz

*Raanan Raz<sup>1</sup>, Marianthi-Anna Kioumourtzoglou<sup>2</sup>, Marc Weisskopf<sup>3</sup>*

*2. Department of Environmental Health Sciences, Columbia University Mailman School of Public Health, New York, NY, United States.*

*3. Departments of Environmental Health and Epidemiology, Harvard T.H. Chan School of Public Health, Boston, MA, United States.*

Abstract: In a recent publication of ours, we implemented a distributed lag model with autism spectrum disorders (ASD) data and NO<sub>2</sub> models from Israel that are highly resolved in time and space. When mutually adjusted, postnatal exposures had positive associations, while prenatal exposures had negative peak around the end of the 1st trimester. We suggest two possibilities in which the apparently protective associations could be the result of live-birth bias. The first possibility results from selection that affects the distribution of exposures in the analyzed sample. Selecting on live births may result in a group less likely to have co-exposure to both high air pollution and other causes of ASD that also affect the likelihood of live birth. In the analyzed sample, those with high exposure are less likely to have other causes of ASD (and thus a lower ASD prevalence) compared with those with lower exposure. This scenario will be described in a directed acyclic graph demonstrating conditioning over a collider. In order for the bias to act, only two assumptions need to hold: (a) air pollution during pregnancy affects the chance of a live birth; and (b) another variable (U) exists that affects both the chance of a live birth and ASD. The second possibility is that air pollution selects into the analyzed sample (live-born children) fetuses that are less susceptible to developing ASD later on. For a paradoxical protective association to arise with an exposure like air pollution, the key factor is that air pollution must lead to fetal loss preferentially among fetuses who are more susceptible to ASD (because of any other factor, e.g. genetic factors). In this case, the proportion of susceptible fetuses selected into the analysis sample (live-born children that survive to the age of ASD diagnosis) will vary across air pollution levels, with lower relative proportion of susceptible fetuses at higher exposures.

## **S02.01.14. Seeing the Invisible: A Novel Epidemiological Approach**

Marc Weisskopf

*Marc Weisskopf<sup>1</sup>, Marianthi-Anna Kioumourtzoglou<sup>2</sup>, Ander Wilson<sup>3</sup>, Raanan Raz<sup>4</sup>*

*1. Environmental Health and Epidemiology, Harvard TH Chan School of Public Health, Boston, MA, United States.*

*2. Environmental Health Sciences, Columbia University Mailman School of Public Health, New York, NY, United States.*

*3. Statistics, Colorado State University, Fort Collins, CO, United States.*

*4. Braun School of Public Health and Community Medicine, The Hebrew University of Jerusalem, Jerusalem, Israel.*

Abstract: When all events of an outcome cannot be counted, there is risk that bias can be introduced to analyses, or even difficulty conducting basic analyses. An example is pregnancy loss, because many of these events never come to medical attention, and some may not even be recognized by the mother. This greatly limits the research that can be done into risk factors for pregnancy loss. We describe here a novel approach to the epidemiologic investigation of risk factors for pregnancy loss that takes advantage of the fact that the total number of conceptions in a given period of time is the sum of live births that result from those conceptions (live birth-identified conceptions) and those that are lost. Thus, associations with pregnancy loss—even with those that go undetected—can be inferred from results of analyses of live births. Here we describe a novel inferred effects approach, its implementation, and assumptions required for causal inference. This new approach could be a powerful approach to study effects on events that have to date been hidden to epidemiologists. The study of pregnancy loss is one example where such an approach could open up new research avenues, but we anticipate that other settings may also lend themselves to such an approach.

## **S02.01.15. Traffic-Related Air Pollution and Pregnancy Loss**

Marianthi-Anna Kioumourtzoglou

*Marianthi-Anna Kioumourtzoglou<sup>1</sup>, Raanan Raz<sup>2</sup>, Ander Wilson<sup>3</sup>, Marc Weisskopf<sup>4</sup>*

- 1. environmental health sciences, columbia university mailman school of public health, New York, NY, United States.*
- 2. Braun School of Public Health and Community Medicine, The Hebrew University of Jerusalem, Jerusalem, Israel.*
- 3. Department of Statistics, Colorado State University, Fort Collins, CO, United States.*
- 4. environmental health, harvard th chan school of public health, Boston, MA, United States.*

**Abstract:** Background. Traffic-related air pollution has been linked to multiple adverse pregnancy outcomes. However, few studies have examined pregnancy loss, targeting losses identified by hospital records, a large limitation as it does not capture events not reported to the medical system. Methods. We used a novel variation of the time-series design to determine the association, and identify the critical window of vulnerability, between week-to-week traffic-related air pollution and conceptions resulting in live births, using nitrogen dioxide (NO<sub>2</sub>) as a traffic emissions tracer. We used information from all live births recorded at Beth Israel Deaconess Medical Center (BIDMC) in Boston, MA (2000-2013) and all live births in Tel Aviv District, Israel (2010-2013). For exposure assessment, in Boston we used the average of 5 urban monitoring sites, while in Tel Aviv the district average of a spatio-temporal prediction model. Results: In Tel Aviv District, the strongest estimate was during the 16th gestational week; for every 10 ppb of NO<sub>2</sub> we observed a decreased rate of live births (RR=0.82; 95%CI: 0.76-0.90), using live-birth identified conceptions to infer pregnancy losses. In Boston, the strongest estimate was during the 15th gestational week; we observed a RR = 0.87 (95%CI: 0.78-0.97), among women living within 60 km from BIDMC, and RR = 0.84 (95%CI: 0.74-0.96) in week 17 among those within 20 km from BIDMC. Conclusions: Using weekly conceptions ending in a live birth rather than identified pregnancy losses, we for the first time comprehensively considered the relationship between air pollution and all pregnancy loss throughout gestation. The observed results, with remarkable similarity in two independent locations, suggest that at levels of traffic pollution experienced in Boston and Israel, higher levels are associated with pregnancy loss with strongest estimates between the 10th-20th gestational weeks.

## S02.01D. Exposures and Health Effects Related to Unconventional Oil and Gas Development

### S02.01.16. Endocrine Disrupting Activities of Unconventional Oil and Gas Operations

Christopher Kassotis

*Christopher D. Kassotis<sup>1</sup>, Susan Nagel<sup>2</sup>, Heather Stapleton<sup>1</sup>*

*1. Nicholas School of the Environment, Duke University, Durham, NC, United States.*

*2. Obstetrics, Gynecology, & Women's Health, University of Missouri, Columbia, MO, United States.*

Abstract: Unconventional oil and gas (UOG) production utilizes the high-pressure injection of more than 1,000 industry-reported chemicals across the US to unlock previously inaccessible or unprofitable oil and natural gas deposits. We have directly tested 24 of these chemicals for endocrine disrupting activity and reported antagonist activities of 21, 21, 10, 10, and 7 for the estrogen, androgen, progesterone, glucocorticoid, and thyroid receptors, respectively. We have also previously found elevated nuclear receptor antagonist activities in surface and groundwater from UOG regions in CO, WV, WY, and other areas. To assess potential reproductive and developmental health effects throughout development, we exposed female C57Bl/6 mice to an equimolar mixture of 23 commonly used UOG chemicals at 3, 30, 300, and 3,000 µg/kg/day via their drinking water from gestational day 11 through birth. Prenatal exposure to this mixture at concentrations that are environmentally relevant resulted in adverse reproductive and developmental effects in offspring, including: modulated hormone levels, apparent effects on fertility (decreased sperm count in males and altered ovarian follicle development in females), increased body weights, and altered reproductive and other organ weights. We further characterized the potential mechanisms of UOG chemical-mediated metabolic dysfunction, and demonstrated that UOG wastewater and wastewater-impacted surface water samples at environmentally relevant concentrations could promote adipocyte development in vitro via both peroxisome proliferator receptor gamma (PPARγ)-dependent and independent mechanisms. We have previously reported PPARγ-independent adipogenic activity for various ethoxylated surfactants, some of which are included in the mixture of 23 UOG chemicals utilized above, though have not identified putative PPARγ-dependent adipogenic chemicals in these samples. This work highlights the importance of evaluating health near UOG operations.

## **S02.01.17. Environmental Monitoring for Unconventional Oil and Gas Development**

Nicole Deziel

*Nicole Deziel<sup>1</sup>, Elise Elliott<sup>1</sup>, Desiree Plata<sup>2</sup>, James Saiers<sup>3</sup>*

- 1. Environmental Health Sciences, Yale School of Public Health, New Haven, CT, United States.*
- 2. Yale School of Engineering and Applied Sciences, New Haven, CT, United States.*
- 3. Yale School of Forestry and Environmental Studies, New Haven, CT, United States.*

**Abstract:** Background: Over 4 million people live within one mile of an unconventional oil and gas (UOG) well. Quantitative environmental monitoring data and models are needed to advance understanding of the complex inter-relationships between UOG activity, water and air quality, and human exposures. Methods: In a preliminary exposure study of 66 homes in Belmont County, Ohio, we measured the volatile organic compounds (VOCs) benzene, ethylbenzene, and toluene in air inside and outside homes with passive charcoal badges. We analyzed drinking water samples for 13 UOG-related VOCs, gasoline-range organics (GRO), and diesel-range organics. Using UOG well coordinates from the Ohio Department of Natural Resources, we calculated several metrics capturing residential proximity to multiple UOG wells. Results: Detection rates were low for the air samples; no associations between well proximity metrics and air VOC detection or concentrations were observed. Distance to nearest well was negatively correlated with drinking water concentrations of GRO, toluene, and certain disinfection byproducts linked with UOG wastewater. Research underway: To advance upon this work, we are formulating a model quantifying groundwater vulnerability to UOG contamination by augmenting proximity information with hydrological data. We are collecting water samples from hundreds of homes across Pennsylvania and Ohio and analyzing them for a range of inorganic and organic compounds using new analytical chemistry techniques to aid in source attribution. Conclusions: Low detection rates impeded air monitoring inferences; more sensitive techniques are needed at a greater number of homes. Our new water vulnerability model could be used to prioritize monitoring or assign exposures in epidemiologic studies. Our inter-disciplinary approach (hydrogeology, chemistry, exposure science) to UOG environmental monitoring has the potential to provide important insights into human exposure potential via the drinking water pathway.

## **S02.01.18. Gestational Exposure to Volatile Organic Compounds (VOCs) and Trace Metals in a Region of Intensive Hydraulic Fracturing for Natural Gas Exploitation**

Élyse Caron-Beaudoin

*Élyse Caron-Beaudoin<sup>3</sup>, Jonathan Chevrier<sup>1</sup>, Pierre Ayotte<sup>2</sup>, Michèle Bouchard<sup>3</sup>, Maryse Bouchard<sup>3</sup>, Katherine L. Frohlich<sup>3</sup>, Marc-André Verner<sup>3</sup>*

*1. Department of Epidemiology, Biostatistics and Occupational Health, McGill University Faculty of Medicine, Montreal, QC, Canada.*

*2. Axe Santé des Populations et Pratiques Optimales en Santé, Centre de Recherche du CHU de Québec-Université Laval, Quebec, QC, Canada.*

*3. Université de Montreal Public Health Research Institute (IRSPUM), Université de Montreal, Montreal, QC, Canada.*

**Abstract:** Background: The Peace River Valley (Northeastern British Columbia, Canada), located on the Montney formation, is an area of intensive hydraulic fracturing for natural gas exploitation. Hydraulic fracturing operations can release contaminants that have been associated with adverse birth outcomes. Recent studies in the United States found associations between density and proximity of natural gas wells and birth defects, small birth weight and preterm birth. However, no exposure assessment studies have been carried in Northeastern British Columbia. Objective: To evaluate exposure to benzene, toluene and a suite of trace metals in 29 Indigenous (13) and non-Indigenous (16) pregnant women from the Peace River Valley. Methods: Enrolled participants collected urine samples over five consecutive days and provided one hair sample. We measured metabolites of benzene (trans,trans muconic acid (tt-MA), S-phenylmercapturic acid (S-PMA)) and toluene (S-benzylmercapturic acid (S-BMA)) in pooled urine samples from each participant. We measured trace metals in pooled urine samples and in the two centimeters of hair closest to the scalp. Results: The median urinary tt-MA level was 3.5 times higher (182 µg/g creatinine) than that from the general Canadian population (48 µg/g creatinine); in Indigenous participants, the median level was 6 times higher (319 µg/g creatinine). Median urinary and hair levels of barium (1.52 µg/L and 4.48 µg/g of hair), aluminum (7.60 µg/L and 4.37 µg/g of hair), strontium (148.40 µg/L and 4.47 µg/g of hair), and manganese (0.49 µg/L and 0.16 µg/g of hair) were higher in participants than reference median levels established in non-occupationally exposed volunteers. Conclusion: Our results suggest elevated gestational exposure to contaminants in our study population compared to the general population. Documenting gestational exposure to environmental chemicals in this region is paramount to assessing health risks and developing exposure mitigation strategies.

## **S02.01.19. Unconventional Gas Development Activity and Severity of Preterm Birth in the Barnett Shale, TX**

Kristina Whitworth

*Kristina W. Whitworth<sup>1</sup>, Amanda Marshall<sup>1</sup>, Elaine Symanski<sup>1</sup>*

*1. Epidemiology, Human Genetics & Environmental Sciences, University of Texas Health School of Public Health, San Antonio, TX, United States.*

**Abstract:** Background: Studies of the relation between maternal residential proximity to unconventional gas development (UGD) and preterm birth (PTB) are equivocal. No study has presented specific risk estimates by UGD-phase or pregnancy trimester. Methods: We conducted a case-control study among women with singleton births in the Barnett Shale area, TX, November 30, 2010-November 29, 2012. Five controls were individually matched to each PTB case (n=13,328) on age and race/ethnicity and controls' time-at-risk was truncated to equal the matched case's gestational age. We created separate activity metrics representing two phases of UGD for wells  $\leq \frac{1}{2}$  mile of the maternal residence. The inverse distance-weighted (IDW) count of wells in the drilling phase represented the UGD-drilling metric and the IDW sum of gas produced represented the UGD-production metric. Metrics were created for each trimester and the entire pregnancy and categorized as: zero wells (ref), 1st, 2nd, and 3rd tertiles of UGD-activity. Conditional logistic regression was used to examine associations with PTB and multinomial logistic regression was used to examine associations with PTB severity, classified as extreme, very, or moderate PTB. Results: We found increased odds of PTB among women classified in the third tertiles of the UGD drilling (1.2, 1.1-1.4) and production (1.2, 1.1-1.3) metrics. Among women classified in the highest tertile of the UGD production metric, the strongest association was observed during the first trimester (1.2, 1.0-1.4). Risk estimates for the UGD-drilling metric were similar across trimesters. We noted the greatest risk for extremely PTB [third tertile ORs: UGD drilling, 2.0 (1.2, 3.2); UGD production, 1.5 (1.0-2.3)]. Conclusion: Our results suggest differences in phase- and trimester-specific association between UGD and PTB, and indicate particular risk associated with extremely PTB.

## **S02.01.20. Congenital Heart Defects and Intensity of Upstream Oil and Natural Gas Activities in Early Pregnancy**

Lisa McKenzie

*Lisa McKenzie<sup>1</sup>, William Allshouse<sup>1</sup>*

*1. University of Colorado, Aurora, CO, United States.*

Abstract: Our previous study indicated that mothers of infants with congenital heart defects are more likely to live in dense areas of upstream oil and natural gas (O&G) activity. The potential for exposure misclassification was a major limitation of our previous study because it lacked sufficient spatial and temporal granularity to determine the variability in maternal exposures immediately before conception and during early pregnancy or between the intensity of upstream O&G activities. To address this limitation, we applied our newly developed spatial-temporal industrial activity model in a nested case-control study, of 3,324 Colorado singleton-live births between 2005 and 2011 to mothers living in a county where at least 20 O&G well started per 10,000 births between 2004 and 2011. This spatial-temporal activity model allowed us to estimate intensities of specific upstream O&G activities in the three months before conception through the first two months of gestation, the critical development window for the developing heart. Our cases were 65, 179, 38, and 187 children born with a conotruncal, tricuspid valve, pulmonary artery, or aortic valve defect, respectively. Our 2,860 controls were children without a birth defect. We found that, after adjusting for the infant's sex and mother's age, parity, ethnicity, smoking, and proximity to other air pollution sources, mothers of children born with a conotruncal, pulmonary artery, or aortic valve defect were more likely to live in areas of dense upstream O&G activity than in areas with no activity. Our results contribute to the evidence base of the potential for adverse health effects in populations living in close proximity to upstream O&G activities and provide justification for strategies to prevent or reduce exposures and improve health in these populations.

## S02.01E. Fluoride Exposure and Health Outcomes in North America

### S02.01.21. Community Water Fluoridation and Urinary Fluoride Concentrations in a National Sample of Pregnant Women in Canada

Christine Till

*Christine Till<sup>1</sup>, Rivka Green<sup>1</sup>, John G. Grundy<sup>1</sup>, Richard Hornung<sup>2</sup>, E. A. Martinez-Mier<sup>3</sup>, Pierre Ayotte<sup>5</sup>, Gina Muckle<sup>5</sup>, Bruce Lanphear<sup>4</sup>*

- 4. Simon Fraser University, Vancouver, BC, Canada.*
- 5. Centre de Recherche du CHU de Québec, Université Laval, Montreal, QC, Canada.*

**Abstract:** Background: Fluoride exposure in pregnant women who live in regions with and without community water fluoridation has not been established. Objective: To measure urinary fluoride levels during pregnancy using urinary creatinine and specific gravity (SG) as dilution correction standards. Methods: We measured maternal urinary fluoride (MUF) concentrations in spot samples collected in each trimester of pregnancy from 1566 pregnant women living in ten Canadian cities and enrolled in the "Maternal-Infant Research on Environmental Chemicals" cohort. We calculated intraclass correlation coefficients (ICCs) to assess variability in MUF concentrations across pregnancy. We estimated associations between MUF levels, tea consumption, and water fluoride concentrations as measured by water treatment plants using regression analyses. Results: Creatinine-adjusted MUF values (M ± SD; mg/L) were almost two-times higher for pregnant women living in fluoridated regions (0.86 ± 0.34) compared with non-fluoridated regions (0.46 ± 0.50; p<0.001). MUF values had modest reproducibility (ICC = 0.41) and tended to increase over the course of pregnancy. Creatinine-adjusted MUF was positively associated with municipal water fluoride level (B=0.52, 95% CI: 0.46, 0.57), accounting for 24% of the variance after controlling for covariates. Higher MUF concentration correlated with number of cups of black (r = 0.31 to 0.32, p<0.005), but not green tea (r = 0.04 to 0.06). Urinary creatinine and SG correction methods were highly correlated (r = 0.91) and interchangeable in models examining predictors of MUF. Conclusion: Community water fluoridation is a major source of fluoride exposure for pregnant women living in Canada. Urinary dilution correction with creatinine and SG are valid and interchangeable methods for pregnant women.

## S02.01.22. Fluoride Exposure during Fetal Development and Childhood IQ: The MIREC Study

Rivka Green

*Rivka Green<sup>1</sup>, Bruce P. Lanphear<sup>2</sup>, Richard Hornung<sup>3</sup>, David Flora<sup>1</sup>, E. A. Martinez-Mier<sup>4</sup>, Gina Muckle<sup>5</sup>, Pierre Ayotte<sup>5</sup>, Christine Till<sup>1</sup>*

- 4. Indiana University, Indianapolis, IN, United States.*
- 5. Université Laval, Quebec, QC, Canada.*

**Abstract:** Background: The potential neurotoxicity of early life exposure to fluoride, which has sparked controversy about community water fluoridation, is poorly understood. Objective: To test the association between fluoride exposure during fetal development and childhood IQ in a Canadian sample of 510 mother-child pairs enrolled in the Maternal-Infant Research on Environmental Chemicals (MIREC) birth cohort; 38% received "optimal" levels of community fluoridated water. Methods: We measured three maternal urinary fluoride (MUF) concentrations during pregnancy, averaged them and adjusted them for specific gravity. Children's cognitive abilities were assessed using the Wechsler Primary and Preschool Scale of Intelligence-III at 3-4 years of age. We used multiple linear regression analyses to examine covariate-adjusted associations between MUF and IQ, and to test for interaction with child's sex. We retained the following covariates based on theoretical and statistical relevance: city, quality of child's home environment, maternal education, and race. Results: Average MUF concentrations for all women were 0.51 mg/L (+/-0.36; range=0.06-2.44); MUF concentrations were lower in women supplied with non-fluoridated water (0.40 mg/L +/-0.27) than women supplied with fluoridated water (0.69 mg/L +/-0.41). MUF levels were inversely associated with Full Scale IQ in males (B=-4.51, 95% CI: -8.39, -0.63, p=0.02), but not in females (B=2.43, p=0.33). Among males, higher MUF levels were associated with a significantly larger reduction in Performance IQ (B=-4.63, p=0.04) than Verbal IQ (B=-2.85, p=0.14). Sensitivity analyses using MUF adjusted for creatinine and controlling for other known neurotoxins (i.e., lead, mercury and arsenic) did not substantially change the results. Conclusion: An increase of 1mg/L of MUF during prenatal development was associated with a decrease of Full Scale IQ by 4.5 points in young boys.

### **S02.01.23. Prenatal Fluoride Exposure and Cognitive Outcomes in Children at 4 and 6-12 Years of Age in Mexico**

Howard Hu

*Howard Hu<sup>7</sup>, Morteza Bashash<sup>1</sup>, Deena Thomas<sup>2</sup>, E. A. Martinez-Mier<sup>3</sup>, Brisa Sánchez<sup>2</sup>, Nil Basu<sup>4</sup>, Karen E. Peterson<sup>2</sup>, Adrienne S. Ettinger<sup>5</sup>, Robert Wright<sup>6</sup>*

**Abstract:** Background: Some evidence suggests that fluoride may be neurotoxic to children. Few of the epidemiologic studies have been longitudinal, had individual measures of fluoride exposure, addressed the impact of prenatal exposures or involved more than 100 participants. Objective: To discuss our recently published as well as key unpublished results of the association of prenatal exposure to fluoride with offspring measures of intelligence. Methods: We studied participants from the Early Life Exposures in Mexico to Environmental Toxicants (ELEMENT) project. An ion-selective electrode technique was used to measure fluoride in archived urine samples taken from mothers during pregnancy and from their children when 6-12 years of age, adjusted for urinary creatinine and specific gravity, respectively. Child intelligence was measured by the General Cognitive Index (GCI) of the McCarthy Scales of Children's Abilities at age 4 and full scale intelligence quotient (IQ) from the Wechsler Abbreviated Scale of Intelligence (WASI) at age 6-12 years. Results: We had complete data on 299 mother-child pairs, of whom 287 and 211 had data for the GCI and IQ analyses, respectively. Mean (SD) values for urinary fluoride in all of the mothers (n=299) and children with available urine samples (n=211) were 0.90 (0.35) mg/L and 0.82 (0.38) mg/L, respectively. In multivariate models, an increase in maternal urine fluoride of 0.5mg/L (approximately the IQR) predicted 3.15 (95% CI -5.42, -0.87) and 2.50 (95% CI -4.12, -0.59) lower offspring GCI and IQ scores, respectively. Trimester-specific results suggest that exposure during the 1st trimester may have the strongest negative effect. Conclusion: In this study, prenatal fluoride exposure, in the range of exposures reported for other general population samples of pregnant women and non-pregnant adults, was associated with lower scores on tests of cognitive function in the offspring at age 4 and 6-12 years.

## **S02.01.24. Fluoride Exposure and Thyroid Function among Iodine Deficient Adults in Canada**

Ashley Malin

*Ashley Malin<sup>1</sup>, Julia Riddell<sup>2</sup>, Hugh McCague<sup>3</sup>, Christine Till<sup>2</sup>*

*1. Environmental Medicine and Public Health, Icahn School of Medicine at Mount Sinai, New York, NY, United States.*

*2. Psychology, York University, Toronto, ON, Canada.*

*3. Institute for Social Research, York University, Toronto, ON, Canada.*

**Abstract:** Background: Fluoride exposure has the potential to disrupt thyroid functioning, though adequate iodine intake may mitigate this effect. This study is the first population-based study to examine the impact of chronic low-level fluoride exposure on thyroid function, while considering iodine status. Objective: This study used weighted population-based data from Cycle 3 (2012-2013) of the Canadian Health Measures Survey (CMHS), a cross-sectional survey designed to collect health and wellness data and biological specimens on Canadians. Methods: The weighted sample represented 7,543,966 adults aged 18-79 who were not taking any thyroid-related medication. Urinary fluoride concentrations were measured in spot samples using an ion selective electrode and adjusted for specific gravity (UFSG) and creatinine (UFCR). Serum TSH levels provided a measure of thyroid function. Multivariable regression analyses examined the relationship between adjusted levels of urinary fluoride and TSH, controlling for covariates. We tested whether TSH levels were more strongly related to urinary fluoride levels in adults who were moderately-to-severely iodine deficient than in adults who were iodine sufficient, according to World Health Organization reference standards Results: The mean (SD) age of the sample was 46.6 (15.8) years and approximately 17.8% fell in the moderately-to-severely iodine deficient range. Median UFSG and UFCR concentrations were 0.74 mg/L and 0.46 mg/g, respectively. Among iodine deficient adults, a 1 mg/L increase in UFSG was associated with a 0.36 mIU/L increase in TSH [95% CI: -0.03, 0.75;  $p = 0.03$ ], and a 1 mg/g increase in UFCR was associated with a 0.61 mIU/L increase in TSH [95% CI: 0.22, 0.99;  $p < 0.01$ ]. Conclusion: Adults living in Canada who have moderate-to-severe iodine deficiencies and higher levels of urinary fluoride may be at an increased risk for underactive thyroid gland activity.

## **S02.01.25. Fluoride Exposure and Dental Enamel Fluorosis**

E. Martinez-Mier

*E. A. Martinez-Mier<sup>1</sup>*

*1. Cariology, Operative Dentistry and Dental Public Health, Indiana University School of Dentistry, Indianapolis, IN, United States.*

Abstract: At appropriate levels, fluoride has been established as an effective agent in the prevention of dental caries. However, a worldwide increasing prevalence of dental enamel fluorosis, a condition that results from excessive intake of fluoride during tooth development, has raised questions regarding a possible excessive intake of and exposure to fluoride in children. This presentation will review selected studies on the prevalence of dental fluorosis in Mexico. Results from studies conducted in naturally fluoridated areas where water content is above optimal, as well as studies conducted in areas where water has negligible, unknown or optimal amounts of fluoride and fluoridated salt is distributed, will be presented. In addition, results from studies on fluoride intake and exposure in Mexico will be discussed. Findings from a recent epidemiological study that assessed dental enamel fluorosis clinically and through the use of imaging technology as well as fluoride intake and exposure in Mexican children will be presented. Finally, trends on the prevalence of enamel fluorosis in Mexico over the last four decades (before and after the introduction of salt fluoridation) will be discussed. The presentation and discussion of this evidence will be useful to inform public policy aiming at optimizing the beneficial effects of fluoride while minimizing its detrimental effects.

## S02.01F. Healthy Climate Solutions: What is the Evidence for Health Benefits of Climate Change Mitigation Strategies?

### **S02.01.26. Introduction and Overview of Health Benefits of Urban Climate Mitigation Strategies**

Patrick Kinney

*Patrick Kinney<sup>1</sup>*

*1. Boston University, Boston, MA, United States.*

Abstract: Research has demonstrated a broad range of adverse health impacts that are exacerbated by climate change. Attention has lately turned to the health aspects of climate solutions, including adaptation strategies to avert the worst consequences of rapid climate changes that are already underway, as well as assessments of the health benefits and/or impacts of mitigation actions aimed at reducing human influence on the climate system. For example, the global Healthy-Polis consortium, launched in 2013, is a global network focused on protecting and promoting urban health through multi-disciplinary, policy-relevant research on urban environmental health and sustainability. Climate change mitigation plans are reducing emissions of climate-damaging pollutants such as CO<sub>2</sub>, methane, and black carbon through strategies such as energy efficiency, increased use of renewables, reduced automobile dependency, urban greening, and others. While designed to achieve long-term carbon emission reduction goals, these mitigation strategies have the potential to achieve local public health benefits that accrue in the near term, both in space and time. Here I provide an overview and introduction to health benefit assessments for interventions related to mobility, buildings, and green space.

## **S02.01.27. Clean Transportation Interventions in Cities**

Mark Nieuwenhuijsen

*Mark Nieuwenhuijsen<sup>1</sup>, Natalie Mueller<sup>1</sup>, David Rojas-Rueda<sup>1</sup>*

*1. ISGlobal, Barcelona, Spain.*

**Abstract:** Background and aims: Research over recent years has convincingly demonstrated a broad range of adverse health impacts that are exacerbated by climate change. Climate change mitigation involves reducing emissions of climate-damaging pollutants such as CO<sub>2</sub>, methane, and black carbon through strategies such as energy efficiency, increased use of renewables, reduced automobile dependency, urban greening, and others. The aim of this session is to present some recent examples of proposed clean transportation interventions in cities worldwide and the impact on health.

**Method:** We obtained some recent examples of proposed and implemented clean transportation interventions in cities and demonstrate the impact on health and the economy. We focus on measures to reduce car use and promote public and active transportation. The studies considered multiple environmental and behavioral risk factors (e.g. air pollution, noise, traffic incidents, physical activity, green spaces and temperature) and multiple outcomes (cases of mortality, morbidity, disability adjusted life years, and economic costs). **Results:** We will present a number of recent studies estimating the health impacts of clean transportation interventions worldwide including the reduction of car use and increase in cycling, tram and Bus Rapid Transit and changes in the urban setting. The studies compare risks and benefits of clean transport interventions. All the studies show a considerable potential beneficial impact on health mainly through the increase of physical activity. **Conclusion:** Clean transportation interventions in cities worldwide cannot only mitigate climate change but also improve public health.

## **S02.01.28. Healthy Suburbs: A Case Study**

Alistair Woodward

*Alistair Woodward<sup>1</sup>, Alex Macmillan<sup>2</sup>, Hamish Mackie<sup>3</sup>*

- 1. University of Auckland, Auckland, New Zealand.*
- 2. University of Otago, Dunedin, New Zealand.*
- 3. Mackie Research, Auckland, New Zealand.*

Abstract: Studies of the low-carbon urban transition have tended to focus on the inner city, since this is where rapid progress can be made most readily. Low density suburbs in new, car-dominated cities have received less attention, although this is the setting in which the majority of the urban population live, in many countries. Why are these parts of the city neglected, and what prospects exist for climate mitigation with health co-benefits? I will attempt to answer these questions, with reference to early results from Te Ara Mua - Future Streets, a controlled before-after intervention study of street improvements to improve safety and increase walking and cycling. The setting is a low-income Auckland suburb with a high proportion of Maori and Pacific residents. Outcomes include physical activity, air quality, greenhouse gas emissions, injuries and social wellbeing.

## **S02.01.29. Urban and Transport Planning Related Exposures and Mortality: A Health Impact Assessment Study for Bradford, UK**

Natalie Mueller

*Natalie Mueller<sup>1</sup>, David Rojas-Rueda<sup>1</sup>, Haneen Khreis<sup>2</sup>, Ana Espinosa<sup>1</sup>, Carles Mila<sup>1</sup>, Marta Cirach<sup>1</sup>, Brian Kelly<sup>3</sup>, Rosemary R. McEachan<sup>3</sup>, John Wright<sup>3</sup>, Mark Nieuwenhuijsen<sup>1</sup>*

*1. ISGlobal, Barcelona, Spain.*

*2. Texas A&M Transportation Institute, College Station , TX, United States.*

*3. Bradford Institute for Health Research , Bradford, United Kingdom.*

**Abstract:** Introduction: By 2050, almost 70% of people globally are projected to live in cities. As the environments we inhabit affect our health, urban and transport designs that promote healthy living are needed. We estimated the number of preventable premature deaths under compliance with international exposure recommendations for physical activity (PA), air pollution, noise, and access to green spaces in Bradford, UK. Methods: We applied the Urban and Transport Planning Health Impact Assessment (UTOPHIA) tool to Bradford. Exposure data of PA, air pollution, noise, and access to green spaces were available for 393,091 Bradford residents  $\geq 18$  years at the Lower Super Output Area (LSOA; N=310) level. We compared recommended with current exposure levels. We quantified the associations between exposures and mortality and calculated population attributable fractions to estimate the number of preventable premature deaths. We also modeled changes in life expectancy and economic impacts. Results: Annually 376 premature deaths (95% CI: 277-475) were estimated to be preventable under compliance with exposure levels for PA, air pollution, noise, and access to green spaces. The biggest share in preventable deaths was attributable to increases in PA (327 deaths; 95% CI: 245-441), followed by reductions in air pollution and noise and increases in access to green spaces. Compliance was estimated to increase average life expectancy by 349 days (95% CI: 210-495) and result in economic savings of almost £ 60,000 per person (95% CI: 36,028-85,087). Residents of LSOAs which are classified as more deprived and more ethnically diverse were estimated to be more adversely exposed and to die more prematurely. Conclusions: Results of HIAs of urban and transport planning related performance are important for cities (1) to identify local health hazards, (2) to better understand the associated health burden and its distribution among the population, and (3) to formulate targeted mitigation strategies.

## S02.01G. New Approaches for Environmental Health Impact Studies: Assessing Human Health Risks from Chemical and Non-Chemical Stressors

### **S02.01.31. Assessment of Human Health Risk Using a Variety of Risk Assessment Approaches**

Elizabeth Miesner

*Elizabeth A. Miesner<sup>1</sup>, Debra Kaden<sup>1</sup>*

*1. Health Sciences, Ramboll US Corporation, San Francisco, CA, United States.*

**Abstract:** Human Health Risk Assessments (HHRAs) have been widely used for decades to quantitatively evaluate potential adverse health effects of exposures to environmental hazards. In guidance and application, HHRA has focused on the potential toxicity of the chemical component of exposure, but does not address other factors that may have public health consequences such as economic, social and planning factors. Most HHRAs do not address the combined impact of different types of exposure, which may disproportionately affect some racial, ethnic and socioeconomic groups. Both chemical and non-chemical stressors (e.g. physical [radiation, noise, vibration, temperature], biological [allergens, molds, pathogens], and social [stress, behaviors, lack of resources]) may impact the health of individuals and communities. Several alternative methods of assessing cumulative environmental stressors and health impacts on a community level have been developed including Health Impact Assessments (HIAs) and Cumulative Risk Assessments (CRAs). HIA is an emerging strategy to assess effects on non-traditional stressors on public health. It is used and promoted as an alternative or complement to HHRA. HIA also includes consideration of benefits, as well as adverse impacts. CRA is an analysis, characterization, and possible quantification of the combined risks to health or the environment from multiple agents or stressors. USEPA came out with their document "The Framework for Cumulative Risk Assessment" in 2003 as the first step in a long-term effort to develop cumulative risk assessment guidance, and it has recently been applied in multiple environmental settings. This talk describes methods to assess site-specific risks to human health, including the more traditional HHRA process, as contrasted to HIAs and CRAs and. The pros and cons of each procedure will be discussed, with an eye towards highlighting the strengths of each.

## **S02.01.32. Using Health Impact Assessments to Assess Potential Health Impacts of Local Infrastructure Projects: A Case Study**

Anushree Bhatt

*Anushree Bhatt<sup>1</sup>, Faiza Waheed<sup>1</sup>, Glenn Ferguson<sup>1</sup>*

*1. Intrinsic Corp., Mississauga, ON, Canada.*

Abstract: Rapid population growth in Ontario has resulted in a need for new infrastructure, including wastewater treatment plants (WWTPs). In support of a previously completed Environmental Assessment for a proposed WWTP, a Health Impact Assessment (HIA) is currently being conducted to assess the potential positive and negative health impacts due to the project to a First Nations Community (FNC). The HIA process is complementary to existing risk assessment and environmental assessment protocols where human health is viewed, not only from the perspective of environmental exposure to chemicals in the built and natural environments, but in terms of various health determinants such as physical health, mental well-being, and social, cultural and economic factors. The ongoing HIA, while providing a platform to enhance communication and address the concerns of the FNC, will recommend measures to enhance the potential positive impacts and mitigate any negative impacts due to the project. To determine the scope of the HIA, potential health issues of concern to the FNC due to the proposed WWTP, were identified and then reviewed through discussions with the FNC, public health and municipal officials, and other stakeholders. The engagement process identified that the main health determinants to be assessed in the HIA include: surface water quality with regards to pharmaceuticals and personal care products, food security, climate change, access to drinking water, impacts to cultural values and traditions, and the social and mental wellbeing of the FNC. Although this HIA is ongoing, initial results indicate that the HIA process will play an important role in establishing an unbiased means of communication between municipalities and FNCs. In general, HIAs are not intended to be advocacy tools; rather they are intended to provide further consideration of potential health outcomes of a given project or policy.

### **S02.01.33. An Analysis of the Use of Various Health Assessments Tools in the Natural Gas and Oil Development Sector**

Uni Blake

*Uni Blake*<sup>1</sup>

*1. American Petroleum Institute, Washington, DC, United States.*

Abstract: The past decade saw an increase in natural gas and oil development in the United States. The increase was mainly due to an innovative use of previously utilized technology, which made it possible to access shale resources that had been considered uneconomical for development. Shale basins cover a broad expanse of regions, underlying communities that were traditionally unaccustomed to industry operations. The rate at which development activities spread across the regions, led to community concerns about potential health impacts from both chemical and nonchemical stressors. Theoretically, using alternative assessments tools, including health impact assessments (HIAs), to address the concerns is seen to have value. Not only do HIAs provide the necessary recommendations that are required to improve positive public health outcomes and minimize the adverse health outcomes of projects, HIAs foster cross-sectoral collaborations which are crucial to developing solutions with maximum stakeholder buy-in. However, the adoption of these alternative tools in the U.S. has been slow as there is varying interest in the use of assessment tools in natural gas and oil development. Using HIA's as a case study, this presentation discusses examples of where HIAs have been used in the sector and identifies some of the challenges and potential solutions.

## **S02.01.34. Methods for Modeling Exposures and Health Risks from Combined Chemical and Non-Chemical Stressors**

Jonathan Levy

*Jonathan Levy<sup>1</sup>, Veronica M. Vieira<sup>2</sup>, Maayan Yitshak-Sade<sup>3</sup>, M. Patricia Fabian<sup>1</sup>, Susan A. Korrick<sup>4</sup>, Antonella Zanobetti<sup>3</sup>*

- 1. Environmental Health, Boston University School of Public Health, Boston, MA, United States.*
- 2. University of California-Irvine, Irvine, CA, United States.*
- 3. Harvard T.H. Chan School of Public Health, Boston, MA, United States.*
- 4. Brigham and Women's Hospital and Harvard Medical School, Boston, MA, United States.*

**Abstract:** Background: Although there is increasing interest in cumulative risk assessment and related approaches to characterize health impacts from multiple stressors, methodological challenges remain. Published epidemiological studies rarely report associations in a manner applicable for cumulative risk assessment, and multi-stressor exposure data are often lacking. We provide two examples that illustrate the strengths and weaknesses of novel methods for characterizing multi-stressor exposures and associated health risks. Methods: In one case, we utilized biomarker and questionnaire data from a prospective birth cohort study to develop exposure regression models that can be used to estimate exposures in a population-based surveillance database. We used generalized additive models (GAMs) to investigate the association between the predicted exposures, other stressors, and teen pregnancy. In the second case, we used sociodemographic Census information, temperature and air pollution predictions from satellite-based models, and other GIS data to characterize exposures for all Massachusetts births, and we applied elastic nets and Bayesian kernel machine regression (BKMR) to select among candidate variables and determine multi-stressor associations with birth weight. Results: Regression models explained exposure variability as a function of sociodemographics, birth address, and birth year. GAMs yielded valuable insights regarding non-linear interactions among stressors that would not have been identified through conventional approaches. While elastic net and BKMR models yielded different subsets of predictors, constrained model-building strategies helped identify the combinations of stressors associated with birth weight. Conclusions: Exposure modeling that leverages population-specific measurements and extensive GIS data, coupled with epidemiological approaches selected with cumulative risk assessments in mind, provide value insight on the health effects of combined exposures.

## **S02.01.35. The Territorialized Exposome Concept to Characterize Cumulative Risk at the Population Level**

Julien Caudeville

*Julien Caudeville<sup>1</sup>, Sarah Habran<sup>2</sup>, Corentin Regrain<sup>1</sup>, Roseline Bonnard<sup>1</sup>, Florence Zeman<sup>1</sup>, Suzanne Remy<sup>2</sup>, Celine Brochot<sup>1</sup>*

- 1. Chronir Risk Division, INERIS, Verneuil en Halatte, France.*
- 2. ISSEP, Liege, Belgium.*

**Abstract:** Risk assessors and risk managers are currently facing two realities: The need to consider the impact of multiple exposures and combined risks, and the substantial growth of environmental data production at the territory level. The exposome concept has been proposed as an emergent exposure science paradigm for conceptualizing the cumulative effects of environmental exposures across the whole human life. The need for risk manager to identify population at-risk in the context of substantial data deficiencies that hinder evaluation of cumulative health risks brings the operational declination of the concept at the territorial scale. The characterization of the territorialized exposome implies the development of dynamic, multidimensional, longitudinal approaches, and information systems that require the adoption of transdisciplinary methods of data analysis. Integrated approaches could bring together all information necessary for assessing the source-to--dose continuum using GIS, multimedia exposure and toxicokinetic model. Different approaches could be considered for screening-level analysis of spatialized cumulative risks based on toxicology data or multivariate approach to combine exposure variables at the population level. Several case studies will be presented in a tiered manner to illustrate organized data processing when the ultimate goal of cumulative risk assessment is to identify overexposed population. Review of toxicology data are conducted in order to group substances or risk factors sharing similar toxicological effect. In other cases, finding a common metric for dissimilar risks is not a strictly analytic process, because judgments must be made as how to link two or more separate scales of risks during a deliberative process, including stakeholders to identify operational actions adapted to the policy objectives.

## S02.01H. Research-To-Action Gaps: How Can We Implement Successful Programs to Reduce Exposure to Lead and Other Environmental Contaminants in Low and Middle-Income Countries?

### **S02.01.36. The Challenges of Translating Research into Action for Lead and Other Environmental Contaminants in Low and Middle-Income Countries**

Katarzyna Kordas

*Katarzyna Kordas<sup>1</sup>*

*1. Epidemiology and Environmental Health, University at Buffalo, Buffalo, NY, United States.*

Abstract: The toxic effects of lead were first described many centuries ago, yet to this day, lead continues to be a public health problem and appears as subject of scientific papers. The renewed notoriety of lead follows important recent cases of environmental injustice in the U.S., and increasingly common reporting on lead exposure and poisoning in low and middle-income countries. Arguably, few researchers, communities, or public health officials need additional convincing that lead exposure among pregnant women and young children is a public health problem. Estimates of health and economic impact of environmental or toxic-site exposure to lead for LMIC populations, particularly children, suggest substantial economic and disease burden. Some believe that more epidemiological research on the associations between lead exposure and adverse health outcomes is not only unnecessary but counter-productive because it delays action. The well-known health impacts, and the estimates of economic impacts place greater urgency on incorporating the environment more squarely into prevention efforts for a number of noncommunicable diseases. Despite an enormous amount of research produced globally, and despite clear economic impacts, many LMICs lag in terms of effective or sustained programs or policies exist to address the continuing problem of lead exposure. By 2020, LMICs will account for 33% of global chemical demand and 31% of production, a 10 percentage point increase from mid-1990s. Given the growing list of environmental contaminants of concern for child health and development, and of their increasingly documented mixture effects, the research and policy communities need to engage in conversations that will facilitate the translation of research into action. This brief presentation will lay the groundwork for the symposium by summarizing the patterns and consequences of lead exposure globally, thus underscoring the continued importance of the issue.

## **S02.01.37. Addressing Environmental Exposures through State and National Programs**

Fuyuen Yip

*2. Environmental Health Tracking Program, Centers for Disease Control and Prevention, Atlanta, GA, United States.*

Abstract: Environmental hazards found in the air, water, soil, and built environment are contributing to chronic diseases affecting health and quality of life worldwide. According to the World Health Organization, about 12.6 million deaths each year are attributable to unhealthy environments. In the US, environmental factors have been associated with many leading causes of death including: cancer, unintentional injuries, and heart, respiratory, and cerebrovascular diseases. National surveillance systems implemented by the Centers for Disease Control and Prevention (CDC) are paramount to better understanding of environmental hazards, human exposures, and relevant health effects over space and time. The Lead Contamination Control Act of 1988 authorized CDC to initiate efforts to eliminate childhood lead poisoning in the U.S. by supporting state and local agencies to develop programs for surveillance and monitoring of children's blood lead levels. Elevated blood lead levels were the first noninfectious condition to be notifiable at the national level. In 2000, The Pew Environmental Health Commission released a report on the state of environmental health in the U.S. calling for the creation of a coordinated public health system to improve response to environmental threats. The Environmental Public Health Tracking Program was formed in 2002 when Congress authorized funding to establish and develop a nationwide network of integrated health and environmental data that can inform actions to improve the health of communities. This presentation will provide a brief history and overview of two important programs addressing environmental contaminants to highlight successes and key challenges of developing these programs at the national level in collaboration with state and local agencies, Federal partners, and other stakeholders.

## **S02.01.38. The Environmental Contaminants Clinic in Montevideo, a History**

Elena Queirolo

*Elena I. Queirolo<sup>1</sup>*

*1. "Pereira Rossell" Pediatric Hospital , Montevideo, Uruguay.*

Abstract: In year 2000, with the now famous case of lead poisoning among children of the La Teja neighborhood, the city of Montevideo faced a serious public health problem. This presentation will first present the history of lead pollution in Uruguay, and the first political and social responses to the issue, including the creation in 2001 of the "Lead Polyclinic" at the Pereira Rossell Children's Hospital in Montevideo, which is the only University Pediatric Hospital in the country. The mission, function and impact of the Polyclinic will be presented; its professional staff, number of children attended. The Polyclinic closed after 15 years of operation, amid protests from staff and patients' families. The reasons argued for the final closure of the Polyclinic by public health authorities will be presented. Some of the functions and operations of the clinic were divided among other healthcare and laboratory facilities, but the decision to close has left many children without proper health care. The presentation will also discuss lessons learned about the exposure to lead in these 15 years and the impact it is likely to have on the health of children, most of whom come from the lower social classes. The presentation will also include opinions collected and studies conducted that analyze the phenomenon of lead pollution in Uruguay. Amongst them is the realization that the implementation of policies that resulted in the closing of the polyclinic for environmental pollutants, instead of demonstrating a state of alertness to children's environmental health and instead of interest in the continuous advance of knowledge, indicate a minimalization of the problem by decreasing human and material resources allocated to environmental issues.

## **S02.01.39. Disconnect between the Research on Lead's Effects, and Efforts to Generate a Lead Awareness and Prevention Program at a National-Level in Mexico**

Martha Téllez-Rojo

*Martha M. Téllez-Rojo<sup>1</sup>*

*1. Center for Health and Nutrition Research, National Institute of Public Health, Cuernavaca, Mexico.*

Abstract: The documentation of lead poisoning in Mexico started at the beginning of XIX century, clearly identifying the use of traditional ceramics to prepare, store and serve food as a source of exposure. These ceramics are produced with a final layer of a lead glaze, which is ideal for the low-temperature domestic kilns. The use of these ceramics is deeply embedded in Mexican culture, but with every use in cooking or serving of food, lead leaches out. Thus, ceramic ware constitutes an important source of exposure for both the end-users and artisan-producers and their families. Much epidemiological research has been conducted by our research group to assess the toxic effects of lead exposure on a wide variety of outcomes through the ELEMENT and PROGRESS cohort studies. Our research has had an impact on lead regulation in several countries, including the U.S. and Mexico. In Mexico, the reference blood lead level for pregnant women and 0-15 year old children was 10 µg/dL until 2017, when it matched the Centers for Disease Control and Prevention (CDC) level of 5 µg/dL. Nevertheless, there is no routine surveillance program or social interventions to prevent lead exposure; furthermore, there is no public awareness of lead's toxicity. This talk will present the efforts conducted by our research group to generate supporting evidence that lead exposure is a public health problem in Mexico and should be addressed. Effects of lead exposure are subclinical, especially at low levels, and compete with other prominent health concerns such as obesity or diabetes. The strategies used by our group to generate evidence aimed at policy makers are designed in the context of scarce economic resources; therefore, lessons learned could be useful to other countries in similar situations.

## 002.02A. Advances in Ambient Air Pollution Modeling 1

### 002.02.01. A Parsimonious Approach to National Prediction: Criteria Pollutants in the Contiguous U.S., 1979 - 2015

Sun-Young Kim

*Sun-Young Kim<sup>1</sup>, Matthew Bechle<sup>3</sup>, Steve Hankey<sup>2</sup>, Lianne Sheppard<sup>3</sup>, Adam Szpiro<sup>3</sup>, Julian Marshall<sup>3</sup>*

- 1. National Cancer Institute, Goyang, Korea (the Republic of).*
- 2. Virginia Tech, Blacksburg, VA, United States.*
- 3. University of Washington, Seattle, WA, United States.*

**Abstract:** **INTRODUCTION:** Many cohort studies have relied upon prediction models to estimate individual-level long-term exposure to air pollution. These models commonly include hundreds of geographic variables; however, employing a smaller subset of these variables may yield similar predictions. This study aimed to explore a parsimonious modeling approach using subsets of geographic variables to develop national exposure prediction models for six criteria pollutants during 1979-2015 for the contiguous U.S. **METHODS:** We computed annual average (1979-2015) concentrations from US EPA regulatory monitoring stations for criteria pollutants (PM10, PM2.5, NO2, SO2, CO, O3) at all available sites that met our inclusion criteria. We also computed ~350 geographic variables such as traffic, population, and land use. Then, we applied a parsimonious version of a previously-developed national prediction model. This model was constructed in a universal kriging framework including summary predictors, estimated by partial least squares (PLS) from geographic variables, and spatial correlation. For the parsimonious models, we tested three approaches using: (1) no geographic variables, (2) a limited number of variables chosen by forward selection from all as input data for PLS, and (3) all variables. We evaluated model performance using 10-fold cross-validation. **RESULTS:** Models using between 3 and 30 selected variables generally gave the best performance across pollutants and years (median R<sup>2</sup>=0.47-0.87) compared to kriging with no and all geographic variables (0.29-0.71; 0.33-0.84). NO2 and PM2.5 showed large differences between models with 3-30 vs. no variables (0.87 vs. 0.61; 0.86 vs. 0.71). SO2 and ozone had small differences among the three approaches (0.57-0.59; 0.71-0.75). **CONCLUSION:** Our findings suggest that a national prediction model built on only a small number (30 or fewer) of important geographic variables selected from the hundreds can provide robust estimates of concentrations.

**002.02.02. National PM2.5 and NO2 Spatiotemporal Models Integrating Intensive Monitoring Data and Satellite-Derived Land Use Regression in a Universal Kriging Framework in the United States: 1999-2016**

*3. Civil and Environmental Engineering, University of Washington, Seattle, WA, United States.*

**Abstract:** Background: Recent nationwide PM2.5 and NO2 exposure models increasingly incorporate land-use regression, satellite-derived observations and spatial smoothing to improve prediction accuracy for epidemiological studies. However, those studies exclusively relied on exposure data from routine monitoring sites that could be less useful for small spatial-scale predictions. Objectives: To develop regionalized national models in estimating PM2.5 and NO2 exposures with high spatiotemporal resolution from 1999 to 2016 in the United States. Methods: We collected monitoring data from numerous regulatory (number of monitors: 1495 [PM2.5], 754 [NO2]) and cohort-specific monitors (939 [PM2.5], 2573 [NO2]) that captured fine-scale residential and roadway exposure gradients. We established a novel modeling framework that incorporated all of the unbalanced monitoring data with land use regression and universal kriging using dimension-reduced predictor variables from satellite observations and a large geographic database. Results: Ten-fold cross-validations showed good model performances with total spatiotemporal R2s of 0.82 and 0.81 for PM2.5 and NO2 using the left out routine monitors. We observed larger within-city spatial variations (coefficient of variation [CV]) from the best models that accounted for cohort-specific monitors than the models that completely relied on routine monitoring sites (increased % of CV: 20-27% for PM2.5, 23-32% for NO2). Regional spatial R2 was highest in the southeast region (0.91) for PM2.5 and lowest in the northwest region (0.71), but was generally the same for NO2 across regions (0.84-0.87). Including satellite PM2.5 or NO2 data moderately improved predictions for points far from monitoring locations. Conclusion: Our models can make accurate point predictions of PM2.5 and NO2 concentrations at both short and long time scales when utilizing additional data from a large number of fine-scale monitors and satellite technology.

### **002.02.03. National PM2.5 and NO2 Exposure Models for China Based on Land Use Regression, Satellite Measurements, and Universal Kriging**

**Abstract:** Introduction: China is the country with the largest number of air pollution deaths per year. Our research aims to improve the spatial resolution of national air pollution estimates for China. We develop and evaluate national empirical models for China incorporating land-use regression, satellite measurements, and universal kriging (UK). Methods: We employ regulatory monitoring data for PM2.5 and NO2 for 2014 and 2015, and ~300 geographic covariates, including categorized "points of interest" (i.e., gas stations, factories, bus stops etc.). Our tests of model performance include (1) forward stepwise linear regression vs. partial least squares (PLS) regression modeling, (2) with and without satellite measurements, and with and without UK, (3) 10-fold cross-validation (CV), leave-one-province-out CV (LOPO-CV), and leave-one-city-out CV (LOCO-CV). Results: UK improves models in well-sampled areas, whereas satellite data substantially improves performance at locations far from monitors. Stepwise linear regression performs similarly to PLS in 10-fold CV, but better in LOPO-CV. Our best models, with forward selection and UK, provide good predictions of ambient PM2.5 (10-fold R2: 0.89 for both 2014 and 2015) and NO2 (10-fold R2: 0.73 and 0.78 for 2014 and 2015, respectively). Population-weighted concentrations during 2014 - 2015 decreased for PM2.5 (from 59 to 52  $\mu\text{g}/\text{m}^3$ ) and NO2 (from 30 to 27  $\mu\text{g}/\text{m}^3$ ). Conclusion: We produced the first high-resolution national LUR-based models for China. Maps (1 x 1 km<sup>2</sup>) of concentrations reveal important spatial gradients in China; we will make those data publicly available online.

#### **002.02.04. Using Geostatistical Simulation to Inform the Quantity and Placement of New Monitors for a Follow-Up Air Sampling Campaign**

Abstract: Sampling campaign design is a crucial aspect of air pollution exposure studies. Selection of both monitor numbers and locations is important for maximizing measured information, while minimizing bias and costs. We developed a two-stage geostatistical based method using pilot NO<sub>2</sub> samples from Lanzhou, China with the goal of improving sample design decision-making, including monitor numbers and spatial pattern. In the first step, we evaluate how additional monitors change prediction precision through minimized kriging variance. This was assessed in a Monte Carlo fashion by adding up to 50 new monitors to our existing sites with assigned concentrations based on conditionally simulated NO<sub>2</sub> surfaces. After identifying a number of additional sample sites, a second step evaluates their potential placement using a similar Monte Carlo scheme. Evaluations are based on both prediction precision and accuracy. Costs are also considered in the analysis. It was determined that adding 28-locations to the existing Lanzhou NO<sub>2</sub> sampling campaign captured 73.5% of the total kriged variance improvement and resulted in predictions that were on average within 10.9mg/m<sup>3</sup> of measured values, while using 56% of the potential budget. This method allows for informed sampling design by quantifying prediction improvement (accuracy and precision) against the costs of monitor deployment.

## **002.02.05. Potential Overfitting in a Spatio-Temporal Exposure Model Developed with Few Monitoring Sites**

Jia Xu

*Jia Xu<sup>1</sup>, Wen Yang<sup>2</sup>, Bin Han<sup>2</sup>, Xinhua Wang<sup>2</sup>, Zhipeng Bai<sup>2</sup>, Sverre Vedal<sup>1</sup>*

*1. Department of Environmental and Occupational Health Sciences, University of Washington, SEATTLE, WA, United States.*

*2. State Key Laboratory of Environmental Criteria and Risk Assessment, Chinese Research Academy of Environmental Sciences, Beijing, China.*

**Abstract:** Overfitting is a concern with air pollution estimation models that rely on a limited number of monitoring sites. Here we develop spatio-temporal air pollution exposure prediction models using land use regression in a universal kriging framework with temporally rich but spatially poor monitoring data. Two-week average concentrations for six criteria pollutants (PM<sub>10</sub>, PM<sub>2.5</sub>, SO<sub>2</sub>, NO<sub>2</sub>, ozone and CO) from 2014 through 2017 were obtained from 23 administrative monitoring sites in the urban area in Beijing. A large array of geographic covariates (GC) was collected. Exposure prediction models for the air pollutants involved three steps: (1) deriving the smoothed temporal trends from a singular value decomposition; (2) reducing the dimensionality of the collected GC using partial least square regression (PLS); (3) developing spatio-temporal models based on the previous smoothed temporal trends and GC-related PLS scores. Leave-one-out cross validation (LOOCV) was used for prediction accuracy at each of the three steps: All steps (123), steps 2 and 3 (23), steps 1 and 3 (13), and for only step 3. The LOOCV R<sup>2</sup> (R<sup>2</sup><sub>cv</sub>) of the spatio-temporal models (step-3) were 0.86, 0.95, 0.90, 0.82, 0.94, and 0.94 for PM<sub>10</sub>, PM<sub>2.5</sub>, SO<sub>2</sub>, NO<sub>2</sub>, ozone and CO, respectively. The R<sup>2</sup><sub>cv</sub> of step-123 models were 0.76, 0.91, 0.79, 0.27, 0.86 and 0.87, the R<sup>2</sup><sub>cv</sub> of step-13 models were 0.84, 0.94, 0.89, 0.78, 0.94 and 0.94, and the R<sup>2</sup><sub>cv</sub> of step-23 models were 0.76, 0.91, 0.80, 0.29, 0.84 and 0.87 for these air pollutants. Prediction accuracy of the two-week average spatio-temporal models was excellent for all of the pollutants. However, when taking into account the two steps of smoothed temporal trends (step-1) and GC-related PLS scores (step-2) before the model development, evidence of overfitting was found for the step-23 models, due to using LOOCV in obtaining PLS scores. Model performance reflects overfitting when these spatio-temporal models are developed using a limited number of monitoring sites.

## O02.02B. Ambient Air Pollution and Cardiopulmonary Morbidity and Mortality

### O02.02.06. Understanding the Effects of Ambient Air Pollutants on Morbidity in Colombia: A Multi-City & Multi-Pollutant Analysis

Laura Rodriguez-Villamizar

*Laura A. Rodriguez-Villamizar<sup>1</sup>, Julián A. Fernández-Niño<sup>2</sup>, Néstor Y. Rojas-Roa<sup>3</sup>*

*1. Public Health, Universidad Industrial de Santander, Bucaramanga, Santander, Colombia.*

*2. Public Health, Universidad del Norte, Barranquilla, Atlantico, Colombia.*

*3. School of Engineering, National University of Colombia, Bogota, Bogota DC, Colombia.*

**Abstract:** Objective: To estimate the short-term effect of mixtures of ambient air pollutants on respiratory and cardiovascular morbidity in four Colombian cities. Methods: Emergency department (ED) visit records for respiratory and cardiovascular selected diagnosis were obtained for the National Social Protection Information System for the cities of Bucaramanga, Bogota, Cali, and Medellin during 2011-2014. Daily concentrations for six criteria air pollutants were obtained from the National Air Quality Network. Using conditional negative binomial time series analysis with marginal effects we assessed the effect of one-pollutant, two-pollutant and specific mixtures of pollutant models controlling for meteorology and time trends. Rate ratios (RR) were calculated for the joint effect of pollutants. Results: In one-pollutant models increases in gases concentrations were associated with increases in ED visits for respiratory diseases, and increases in gases and particulate matter were associated with increases in ED visits for cardiovascular diseases. The two pollutant models for respiratory diseases showed that the effect of NO<sub>2</sub> alone (RR 1.91 95% CI 1.26-2.55) is higher than the joint effect of any of its combinations (NO<sub>2</sub>+PM<sub>2.5</sub> RR 1.88 95% CI 1.08-2.69) but lower than the effect of PM<sub>10</sub> with SO<sub>2</sub> (RR 2.14 95%CI 1.37-2.93). The two-pollutant models for cardiovascular diseases showed synergistic effects between NO<sub>2</sub> and SO<sub>2</sub> (RR 4.85 95%CI 3.75-5.95) and PM<sub>10</sub> and SO<sub>2</sub> (RR 3.6 95%CI 2.84-4.39). Specific mixtures models showed that the mixture of "oxidant gases" (NO<sub>2</sub>+O<sub>3</sub>+SO<sub>2</sub>) has the higher joint effect on cardiovascular morbidity and the mixture of "traffic-related air pollutants" (NO<sub>2</sub>+CO+PM<sub>2.5</sub>) has the higher joint effect on respiratory morbidity. Conclusions: The results show the health effect of each pollutant and the dominant effect of NO<sub>2</sub> in air pollution mixtures on respiratory and cardiovascular morbidity and the co-dominant effect of SO<sub>2</sub> in mixtures on cardiovascular morbidity.

## **O02.02.07. A Multi-Country Study on Ozone-Related Mortality**

Ana Vicedo-Cabrera

*Ana M. Vicedo-Cabrera<sup>1</sup>, Francesco Sera<sup>1</sup>, Ben Armstrong<sup>1</sup>, Antonio Gasparri<sup>1</sup>*

*1. Department of Public Health, Environments and Society, London School of Hygiene and Tropical Medicine, London, United Kingdom.*

**Abstract:** Many studies have characterized the short-term association between ozone and mortality in different settings, but mostly across limited geographical areas and using different methodological approaches. In this study, we aimed at comprehensively assessing short-term ozone-related mortality associations in a multi-country analysis. **Method:** We collected daily mortality and air pollution data (ozone, O<sub>3</sub>, and particulate matter, PM<sub>10</sub>) from 245 locations in 16 countries (Australia, Brazil, Canada, Chile, Columbia, France, Japan, South Korea, Mexico, Portugal, Spain, Sweden, Switzerland, Taiwan, Thailand, and United States), included in the Multi-City Multi-Country Collaborative Research Network. We applied a two-stage time-series design. First, we modelled mortality-ozone associations across 21 days of lag using quasi-Poisson regression and distributed lag linear models (DLMs). Second, we performed a multilevel multivariate meta-regression to obtain pooled associations across locations nested within country. Best linear unbiased predictions (BLUPs) were derived at both location and country levels. We estimated season-specific ozone-related mortality through time-varying interaction DLMs. **Results:** On average, an increase in 10 µg/m<sup>3</sup> in ozone was associated with a 0.6% increase in mortality risk [95%CI: 0.3 to 0.8%]. The positive association was lagged and persisted during the following 7 days. Country-specific BLUPs ranged between 0.2%[-0.05 to 0.5] in Brazil to 0.8%[0.5 to 1.2] in the US. The ozone-related mortality association was significantly larger in winter [0.8%, 0.5 to 1.0] vs summer [0.5%, 0.4 to 0.7]. Results were robust to sensitivity analyses, such as multi-pollutant models. **Conclusion:** This represents the largest epidemiological study on health effects of ozone. By using a common advanced statistical framework, we provide robust evidence on the association with all-cause mortality in different locations across the globe. On behalf of the MCC Network

**Abstract:** There is limited evidence for short-term associations between mortality and ambient air pollution in the Middle East, and no studies examining the association between daily mortality and the air quality index (AQI). We investigated short-term associations between non-accidental mortality and fine particulate matter (PM<sub>2.5</sub>), nitrogen dioxide (NO<sub>2</sub>), and the AQI from March 2011 through March 2014 in the megacity of Tehran, Iran. Generalized additive quasi-Poisson models were used within a distributed lag non-linear modeling framework to estimate the effects of PM<sub>2.5</sub>, NO<sub>2</sub>, and AQI from lag 0 to lag of 45 days. Positive associations were found in most models, with strong evidence of effect modification by sex, age, and season. The maximum cumulative rate ratios (95% confidence interval) per inter-quartile range increment were: 1.19 (1.12, 1.28) for NO<sub>2</sub> over the previous 45 days (for males, all ages, in cooler months); 1.14 (1.07, 1.21) for PM<sub>2.5</sub> over the previous 30 days (for females, all ages, in cooler months); and 1.15 (1.08, 1.22) for AQI over the previous 31 days (for females, all ages, in cooler months). The cumulative effects remained positive in multipollutant models. Overall, we found that the effects of PM<sub>2.5</sub>, NO<sub>2</sub>, and AQI on mortality in Tehran were immediate, and that they increased steadily over a period of weeks. This is the first study to report short-term association between non-accidental mortality and ambient air pollution in Iran.

## **002.02.09. Association between Haemorrhagic Stroke Incidence and Atmospheric Air Pollutants**

Radoslaw Czernych

*Radoslaw Czernych<sup>1</sup>, Artur J. Badyda<sup>2</sup>, Pawel Zagodzon<sup>1</sup>*

*1. Hygiene and Epidemiology, Medical University of Gdansk, Gdansk, Pomorskie, Poland.*

*2. Department of Informatics and Environment Quality Research, Warsaw University of Technology, Warsaw, Poland.*

Abstract: According to WHO estimates, of the 17.5 million deaths due to cardiovascular disease in 2012, an estimated 6.7 million were due to strokes. Evidence is increasing that short-term exposure to ambient air pollution is associated with increased incidence of haemorrhagic strokes. The purpose of this study is to determine risk of intracerebral haemorrhage (ICH) and subarachnoid haemorrhage (SAH) incidence depending on seasonal variations in air pollutants in the Gdansk agglomeration, Poland. From January 1, 2009 to December 31, 2014, 16,000 ICH and 3,500 SAH were registered among residents of Gdansk agglomeration, Poland. The authors calculated the relative risk (RR) of haemorrhagic stroke and its subtype incidence (I60, I61) based on time-series analyses and trend correlations of air pollution (NO<sub>x</sub>, SO<sub>2</sub>, CO, O<sub>3</sub> and PM<sub>10</sub>) and stroke incidence. The significance in difference in stroke incidence as well as concentrations of the above mentioned air pollutants was assessed using Mann-Whitney's test and t-test respectively. The obtained results indicate an increased, and statistically significant, incidence of strokes during the heating period (November-April). The daily stroke incidence in summer period was 2.22 compared with 2.51 ( $p = 0.002$ ) cases of stroke in heating period. Statistically significant factors increasing the risk of stroke were NO<sub>2</sub> (RR = 1.128,  $p < 0.05$ ), PM<sub>10</sub> (RR = 1.209,  $p < 0.05$ ) and with O<sub>3</sub> with 2 day lag (RR = 1.09,  $p < 0.05$ ). Our research results show the relationship between haemorrhagic stroke incidence and seasonal variations of concentrations of NO<sub>2</sub>, PM<sub>10</sub> and O<sub>3</sub>. The RR of haemorrhagic stroke was higher for a group of people over 65 years of age. Risk determined for women and men did not differ significantly. From our point of view, the assessment of the impact of the environment on the stroke incidence is important from the point of view of environmental policy and the creation of prevention programs, both on a local or global scale.

## **O02.02.10. The Effect of Asian Dust in Estimating the Mortality Effects of Ambient Particles, with Larger Dataset in Seoul, Korea from 1998 to 2015**

Garam Byun

*Garam Byun<sup>2</sup>, Hyomi Kim<sup>2</sup>, Honghyok Kim<sup>2</sup>, Yongsoo Choi<sup>3</sup>, Hyeonjin Song<sup>3</sup>, Sera Kim<sup>2</sup>, Sooyeon Kim<sup>2</sup>, Dahyun Baek<sup>2</sup>, Jong-Tae Lee<sup>1</sup>*

*2. BK21PLUS Program in 'Embodiment: Health -Society Interaction', Department of Public Health Sciences, Graduate School, Korea University, Seoul, Korea (the Republic of).*

*3. Korea University, Seoul, Korea (the Republic of).*

**Abstract:** Background: Asian Dust (AD) is a natural source of particulate matter (PM) in Korea and increase the concentration of PM remarkably. However, the characteristics of PM from AD differ from that of PM in usual days. Objectives: We investigated the effects of Asian dust in association between PM and mortality in Seoul, Korea, 1998-2015. Methods: We applied time-stratified case-crossover design to estimate the effects of PM<sub>10</sub> and PM<sub>2.5</sub> on non-accidental, cardiovascular and respiratory mortality. The effect estimates of PM were compared for all days in study period and days without AD events, with stratified analyses by sex and age group. Results: A 10 µg/m<sup>3</sup> increase in PM<sub>10</sub> and PM<sub>2.5</sub> was associated with a 0.15% (95% CI: 0.06, 0.24%) and 0.27% (95% CI: 0.07, 0.47%) increase in risk of non-accidental mortality, respectively, for all days. The associations were enlarged to 0.30% (95% CI: 0.18, 0.42%) and 0.33% (95% CI: 0.10, 0.55%) when AD days were excluded from the analyses. The difference in effect estimates between all days and non-AD days were larger in males and those who aged under 64 years compared to other groups. Conclusion: The change in composition of PM or behavior pattern of population during AD events might result in the different effect of PM during all days and non-AD days. Our study suggest that including AD days in the analyses is likely to underestimate the effect of PM in usual urban environment.

## 002.02C. Chemical Exposures and Interventions Using Systematic Reviews

### **002.02.11. Developing Criteria for Evaluating the Quality of Exposure Measurements in Epidemiological Studies during Systematic Review**

Rebecca Nachman

*Rebecca M. Nachman<sup>1</sup>, Elizabeth Radke<sup>1</sup>, Leonid Kopylev<sup>1</sup>, Audrey Galizia<sup>1</sup>, Deborah Segal<sup>1</sup>, Glinda Cooper<sup>2</sup>*

- 1. U.S. Environmental Protection Agency, Takoma Park, MD, United States.*
- 2. Innocence Project, New York, NY, United States.*

**Abstract:** During a systematic review of epidemiological evidence on health risk from exposure to environmental chemicals, it may be necessary to develop criteria for evaluating the quality of exposure measurements that account for specific factors relevant to the chemical of interest. We describe approaches for developing chemical-specific criteria through three case studies for exposure to phthalates, methylmercury, and hexavalent chromium. Each case study began with a set of prompting questions aimed at answering the core question: Does the exposure measure reliably distinguish between levels of exposure in a time window considered most relevant for a causal effect with respect to the outcome? We then developed additional follow-up questions specific to each chemical (or class of chemical). We used a range of approaches to address the questions and draft chemical-specific criteria for rating exposure measurements as Good, Adequate, Poor, or Critically Deficient (Good indicating the least potential for bias in effect estimates due to exposure measurement error). The approaches and key chemical-specific criteria were as follows: For phthalates, based on a comprehensive review of the literature, we identified urine as the preferred biological matrix and emphasized repeat sample collection. For methylmercury we consulted multiple independent researchers with expertise in mercury biomonitoring and found agreement on the importance of standard reference materials and quality control related to mercury adherence to analytical equipment. For hexavalent chromium, we used existing guidance to develop criteria that take into account uncertainty due to the reduction of hexavalent chromium to trivalent chromium in air and biological samples. Further development of chemical-specific evaluation criteria can enhance the use of standard systematic review tools. The views expressed in this abstract are those of the author and do not necessarily represent the views or policies of the U.S. EPA.

## **002.02.12. Systematic Review of Mercury Exposures Worldwide: Findings from the 2018 WHO/UN Global Mercury Assessment**

Abstract: The Minamata Convention on Mercury Pollution provides a mandate to take action against global mercury pollution. However, our knowledge of mercury exposures around the world remains limited. As part of the 2018 UN Global Mercury Assessment, WHO led the current study to increase worldwide understanding of human exposures to mercury by collating and analysing mercury concentrations in biomarker samples via a systemic review. A systematic search of the peer-reviewed literature was performed with several a priori search strategies set. The overall work captured 424,884 mercury biomarker measures taken from 336,015 individuals represented in 312 articles from 67 countries. We identified four populations of concern for which there exist a relatively robust dataset: 1) Arctic populations (mainly Inuit) who consume fish and marine mammals; 2) tropical riverine communities (especially Amazonian) who consume fish, and in some cases may be exposed to mining operations; 3) coastal and/or small-island communities who are avid seafood consumers; and 4) individuals who either work or reside amongst artisanal and small-scale gold mining (ASGM) sites. Individuals in select background populations worldwide with insignificant exposures to mercury sources have blood mercury levels that generally fall under 5 mg/L and urine mercury levels that fall under 3 mg/L. This systematic review documents that all people are exposed to some amount of mercury, and that there is great variability in exposures around the world. This type of information is critical in helping understand exposures particularly in light of the Minamata Convention on Mercury Pollution and certain stipulations within the Convention text (e.g., can inform Article 22's effectiveness evaluation especially for vulnerable populations; gauge changes over geographic space and time).

## **O02.02.13. Interventions for Reducing Ambient Air Pollution and Their Effects on Health: Final Results from a Cochrane Systematic Review**

Hanna Boogaard

*Jake Burns<sup>2</sup>, Hanna Boogaard<sup>1</sup>, Lisa Pfadenhauer<sup>2</sup>, Stephanie Polus<sup>2</sup>, Annemoon M. van Erp<sup>1</sup>, Anke C. Rohwer<sup>3</sup>, Ruth Turley<sup>4</sup>, Eva A. Rehfuss<sup>2</sup>*

**Abstract:** Interest in assessing the health effects of air quality interventions has grown in response to questions about the benefit of further tightening air pollution regulations. No systematic review has been performed to date with transparent and standardized protocols. In brief, standardized protocols were followed for study selection, assessing individual study quality and evaluating the body of evidence. Eligible studies assessed the effectiveness of any intervention aiming to reduce ambient PM air pollution from vehicular, industrial, residential or multiple sources with a range of study designs. Primary outcomes were PM concentrations and all-cause as well as cardiovascular and respiratory mortality. After a three-stage duplicate screening process of 33,462 unique titles, we included 44 interventions evaluated in 53 studies in 20 countries in the main analysis. Changes in PM<sub>10</sub> and PM<sub>2.5</sub> were assessed for 22 and 11 interventions, respectively, while only 16 studies assessed changes in health outcomes, including 9, 4 and 5 studies assessing total, cardiovascular and respiratory mortality, respectively. Studies included in the main analysis comprised controlled-before after studies and interrupted time series studies with and without a control site. Study quality varied widely. A graphical summary of the evidence showed that effect estimates were heterogeneous, and only some studies documented improvements in air quality and/or health. Given the few studies and the heterogeneity across interventions, outcomes, and study methods, it was difficult to generate any overall conclusions regarding the effectiveness of interventions in improving air quality or health. The review highlights the numerous challenges encountered such as lack of statistical power, background trends, and difficulties in direct attribution. The review provides possible directions and implications for future practice and research, including the use of causal inference methods that has shown promise.

## **002.02.14. Exposure to Formaldehyde and Effects on Asthma Outcomes: A Systematic Review and Meta-Analysis**

Juleen Lam

*Juleen Lam<sup>1</sup>, Erica Koustas<sup>1</sup>, Patrice Sutton<sup>1</sup>, Amy M. Padula<sup>1</sup>, Michael Cabana<sup>2</sup>, Hanna Vesterinen<sup>1</sup>, Evans Whitaker<sup>2</sup>, Natalyn Daniels<sup>1</sup>, Tracey Woodruff<sup>1</sup>*

*2. University of California, San Francisco, San Francisco, CA, United States.*

**Abstract:** Background: Formaldehyde is found in virtually all homes and buildings. Low-income populations are disproportionately at risk of exposure. The relationship between asthma and exposure to formaldehyde has been under evaluation by government agencies for the last few decades; however asthma was not included in EPA's economic analysis of the benefits of regulating formaldehyde. Objective: We conducted a systematic review to answer the question: "is exposure to formaldehyde associated with diagnosis, signs, symptoms, exacerbation, or other measures of asthma in humans?" Methods: We conducted a comprehensive search of articles published up to February 2018. We included original studies that investigated indoor or outdoor sources of airborne inhalation exposure to formaldehyde incurred any time prior or concurrent to diagnosis or exacerbation of asthma. We developed and registered a protocol in PROSPERO, evaluated the potential risk of bias for each included study, identified a subset of studies combinable in a meta-analysis, and rated the quality and strength of the body of evidence. Results: We screened 4,482 references and identified 148 human studies that met our inclusion criteria; of these, 81 reported on the asthma status of participants; and of these, 10 studies (12 datasets) were deemed combinable in a meta-analysis for development of childhood asthma, 15 were combinable in a meta-analysis for exacerbation of childhood asthma, and 4 were combinable in a meta-analysis for adult asthma outcomes. Studies generally had low to probably-low risk of bias across most domains. A 10-fold increase in formaldehyde exposure was associated with an increased risk of asthma development for both indoor formaldehyde exposure (OR= 2.27 95% CI: [1.26, 4.09]) as well as ambient exposures (OR=1.03, 95% CI: [1.02, 1.04]). The final results of rating the quality and strength of the evidence and recommendations for prevention will be presented.

## **O02.02.15. Exposure Data Curation Using Dragon Online Flexible Forms**

Kevin Hobbie

*Kevin Hobbie<sup>1</sup>, Tom Feiler<sup>1</sup>, Ashley Williams<sup>1</sup>, Heidi Hubbard<sup>1</sup>, Cara Henning<sup>1</sup>*

*1. ICF, Fairfax, VA, United States.*

Abstract: Data curation is particularly challenging when conducting exposure assessments. Because exposure assessment requires integration of input data and measured concentrations from diverse data streams, data collected are in non-standard formats and reflect variability in data reporting. However, gathering and annotating necessary data is a critical step in conducting systematic reviews and exposure and risk assessments. To this end, ICF has developed a flexible data extraction form in DRAGON ONLINE, a web based collaborative platform designed to support all components of systematic literature reviews and exposure and risk assessments. DRAGON ONLINE allows data elements evaluated across scientific studies to be standardized while maintaining the flexibility to extract and store data that is fit for purpose. Flexible data extraction forms can be quickly built to suit the needs of a particular assessment. The web based platforms allows multiple users to extract data simultaneously and maintains records of decisions made throughout the systematic review process. The extracted data and decisions allow for quality control review, exporting of extracted data, and annotation of data curation steps. In this presentation, we will demonstrate forms developed for extraction of measured media concentrations, biomonitoring data, modeled media concentrations, and modeled doses. Extracted data for various environmental chemicals will also be presented in reports, graphs, and charts that support the integration of data across data streams to reach assessment conclusions.

## 002.02E. Household Environmental Risk Factors and Health

### 002.02.21. A Novel Approach to Examining Multiple Indoor Exposures in Early Childhood on the Inflammatory Pathway and Risk of Intermediate Outcomes for Childhood Asthma in the Canadian Healthy Infant Longitudinal Development (CHILD) Birth Cohort

Tim Takaro

*Tim K. Takaro<sup>1</sup>, Martine Vrijheid<sup>2</sup>, Xavier Basagaña<sup>2</sup>, Jaclyn Parks<sup>1</sup>, Allan Becker<sup>3</sup>, James Scott<sup>4</sup>, Diana Lefebvre<sup>5</sup>, Wendy Lou<sup>4</sup>, Piush Mandhane<sup>6</sup>, Padmaja Subbarao<sup>4</sup>, Stuart Turvey<sup>7</sup>, Malcolm Sears<sup>5</sup>, Jeffrey Brook<sup>4</sup>*

**Abstract:** Rationale: Oxidizing chemicals found in the indoor environment, particularly consumer products, can cause inflammation leading to respiratory illness. The CHILD birth cohort is a national study examining how environmental exposures interact with genetics, immune system, microbiome and other personal characteristics to impact the risk of developing asthma and allergies. Methods: 2700 of 3,455 children born into the CHILD cohort were included in this analysis. A comprehensive suite of indoor exposures with potential inflammatory properties (e.g. mold and moisture, cleaning products and other household chemicals, and pests) in infancy were combined into an Indoor Environmental Exposure Index (IEEI). Exposures were evaluated against asthma-related outcomes of recurrent wheeze, atopy and diagnosed asthma at age 3 years. Results: In logistic regression (adjusted for sex, parental atopy, income, ethnicity, and tobacco exposure) the IEEI at age 3 months was associated with a significantly higher risk of asthma and wheeze + atopy at 3 years of age in both continuous and interquartile comparisons, but not with atopy alone. IEEI as Continuous Variable .....IEEI Comparing Upper to Lower Quartile Outcome; Odds Ratio (95 % C.I.); Odds Ratio (95 % C.I.) Asthma 1.39\* (1.03 - 1.86) .....1.98\* (1.02-4.12) Atopy ...1.12 (0.94 - 1.33) .....1.37 (0.91-2.07) Wheeze+Atopy 1.56\* (1.03 - 2.38) 3.53\* (1.23-12.7) \*p-value < 0.05 Conclusions: Infants with wheeze, and wheeze with atopy are at higher risk for developing asthma later in life. Our findings indicate that ubiquitous indoor exposures in the first 3 months of life may contribute to higher risk of wheeze and atopy, which may ultimately lead to asthma later in life. Given the longitudinal nature of CHILD, we can add exposure periods at later ages and track these relationships with more definitive asthma development.

## **002.02.22. The Home Environment and Caregiver Stress of Children with Asthma in Low Income Rural Households**

Abstract: Urban studies demonstrate adverse impacts of home environmental characteristics and caregiver stress on asthma morbidity. We characterize these features at baseline for participants in a rural asthma intervention study (Home Air in Agriculture Pediatric Intervention - HAPI). Staff administer a multi-component stress survey and conduct home environmental assessments. Micropem samplers are placed in the child sleeping area and home living area. Seventy-five child subjects completed the baseline assessments. All are Latino, age 6-12 years, and reside in non-smoking households. Two week geometric mean (GSD) PM2.5 and PM10 concentrations in the sleeping area were 10.6 ug/m<sup>3</sup> (2.2) and 19.9 ug/m<sup>3</sup> (1.8). Living room PM2.5 was 13.4 ug/m<sup>3</sup> (2.2). Visible mold was evident in 61% of homes, detectable by odor in 24%. Other common triggers identified were bleach/ammonia cleaner use (93%), air freshener use (59%), carpeting in the sleeping area (56%), rodent pests (44%), pesticide use indoors (35%), and indoor cat/dog (33%). Few had allergen mattress covers (12%). Approximately one third of caregivers scored in the higher ranges of perceived stress (PSS>15). The child's asthma reportedly caused stress in the family for 41%. Caregivers expressed lack of confidence in handling a severe attack (51%) and concerns for adverse effects of long-term asthma medication use (70%). Hispanic stress inventory components revealed high stress for some participants related to language (19%) and immigration (16%). While understudied, children in rural settings, including immigrant families, may face comparable or higher burden of home conditions, stressors, and resource limitations that threaten asthma control. Measured indoor particulate matter concentrations are lower than most urban studies but consistent with observations in other rural or nonsmoking homes. HAPI will test a community based home visiting and education program alone or with HEPA air cleaners on asthma outcomes in this setting.

## 002.02.23. Longitudinal Residential Exposures and Lung Function Until Age 16

Edith Milanzi

**Abstract:** Background: Exposure to secondhand tobacco smoke (SHS), pets, and dampness and molds have been linked to reduced lung function. Distinct ranges of ages have been studied, but evidence for associations between longitudinal cumulative patterns of exposure and lung function is scarce. We investigated associations of longitudinal exposure to SHS, pets, and dampness and molds from birth/early life until age 14 with lung function growth between ages 12 and 16. Methods: We used data from the Dutch Prevention and Incidence of Asthma and Mite Allergy (PIAMA) cohort (N=1461). Data on residential SHS, pets, dampness and molds exposures, as well as health and lifestyle were obtained by questionnaires during follow up. Lung function (forced expiratory volume in 1 second (FEV1) and forced vital capacity (FVC)) was measured during medical examinations at ages 12 and 16. Time-varying residential exposures from birth/early life into adolescence were characterized into longitudinal patterns using Latent Class Growth Analysis (LCGA). We analyzed the associations of patterns of residential exposures with FEV1 and FVC using linear mixed effects models. Results: SHS exposure patterns were associated with reduced FEV1 growth e.g. -32.6 ml/year (95% confidence interval (CI): -43.4 to -21.7) and reduced FVC growth -20.7 ml/year (-32.9 to -8.4 ) for almost always exposure pattern vs. very low SHS exposure pattern. Pet exposure patterns were associated with increased FEV1 growth e.g. 11.1 ml/year (3.4 to 18.8) for high early life exposure vs. very low pet exposure pattern. Early life exposure to dampness and molds was associated with reduced FEV1 growth (-18.8 ml/year (-27.9 to -9.6 )) and FVC growth (-15.8 ml/year (-26.0 to -5.7 )) as compared to very low dampness and mold exposure pattern. Conclusion: Longitudinal residential exposures to SHS, pets and dampness and molds were associated with lung function growth from 12 to 16 years.

## **O02.02.24. Effects of Short-Term Exposure to Fine and Ultrafine Particles from Indoor Sources on Arterial Stiffness - A Randomized Sham-Controlled Exposure Study of Healthy Volunteers**

Vanessa Soppa

**Abstract:** Introduction: Particulate air pollution is linked to adverse cardiovascular effects, including arterial stiffness. The aim of this study was to investigate the effect of short-term exposure to particles from indoor sources on arterial stiffness, assessed as augmentation index (AIx), augmentation pressure (AP) and pulse wave velocity (PWV). Methods: We used multiple mixed linear regression to analyze the association of particle emissions from 2h candle burning (CB), toasting bread (TB), and frying sausages (FS) with changes in arterial stiffness in 55 volunteers in a randomized cross-over controlled exposure study. Size-specific particle mass (PMC) and particle number concentration (PNC), and lung-deposited particle surface area concentration (PSC) were measured during the 2h exposure. AIx and AP were measured before, directly and 2h, 4h and 24hrs after exposure. PWV was measured directly and 24hrs after exposure. Results: We observed a significant increase in AIx of 6.3% (95%-CI: 1.1; 11.5) in the categorical analysis directly after the exposure CB, PM10 and PM2.5 from TB were associated with increases in AIx up to 4h after exposure, with highest associations for PM2.5 (8.1% (95%-CI: 2.5; 13.7) directly after exposure. PNC from FS and CB, was associated with significant increases of AIx after the exposure FS for all time points (range: 4.1% (95%-CI: 0.5; 7.6) after 2h; 5.9% (95%-CI: 1.5; 10.2) after 24hrs) and directly after the exposure CB (5.6% (95%-CI: 1.0; 10.2). PSC measured during FS was also associated with a 5.4% (95%-CI: 1.4; 9.4) and 4.2% (95%-CI: 0.1; 8.3) increase in AIx directly after and 4h after the exposure, respectively. The results of the PWV showed no distinct associations. Conclusion: Our findings show rapid increases in arterial stiffness in healthy individuals after exposure to typical indoor sources. These changes of central arterial indices differ concerning magnitude, duration, and association to specific particle metrics and particle sources.

## **O02.02.25. Ethical Challenges when Evaluating Household Health Risk**

Carl Grimes

*Carl Grimes<sup>1</sup>*

*1. Hayward Healthy Home Institute, Denver, CO, United States.*

Abstract: Environmental epidemiology for outdoor exposures is well established and accepted. Exposure types and sources plus their relationships to public health are increasingly well-known. But such investigation typically stops at the front door of houses. Which is curious because people spend as much as 90 percent of their time indoors. Mothers, children, and the elderly - arguably the more vulnerable of the population - spend most of that 90% inside their household. Although people are the defined subjects of epidemiology, they are mostly studied as a group larger than that of a typical household; certainly not individually. Finally, the occupants of households are strangely unaware that their personal domain could ever be deleterious to their health. There are at least four questions with ethical implications: What are the justifications for excluding the dominant location of human environmental exposure? Do these arguably valid justifications offset the ethics of excluding the epidemiology of the indoor environment? Does the inherent complexity, along with the challenges associated with the statistical analysis of small groups, ethically justify their exclusion? Do environmental epidemiologists have an ethical duty to inform and alert the general populace of the potential risks of their indoor environment? These questions provide a framework for discussing ethics in this session.

*7. National Institute of Public Health, Mexico City, Mexico.*

**Abstract:** Background: An important concern is the toxic legacy of prenatal lead exposure. During pregnancy, maternal skeletal bone lead from earlier exposures mobilizes and crosses placental barriers placing the developing fetus at risk for lead exposure and subsequent neurobehavioral deficits. Some of the neuronal circuits implicated in mechanisms of neurodevelopment can be probed with simple physiological behavioral paradigms, potentially serving as a neurobehavioral marker of toxicant exposure. One such measure includes pre-pulse inhibition (PPI), a sensorimotor gating process that can modify the acoustic startle reflex (ASR) under different behavioral conditions. PPI impairment has been associated with neurodevelopmental deficits in children such as ADHD and early psychosis. To our knowledge, no studies have examined the effect of prenatal lead concentrations on PPI in children. Objective: The objective of this study was to determine the effect of prenatal bone lead concentrations on PPI in Mexican children 8-17 years of age. Methods: In vivo maternal bone lead measurements were taken at four weeks postpartum at the mid-tibia shaft and the patella using a K-Shell X-ray fluorescence (K-XRF) instrument. PPI responses were recorded in an isolated clinical setting and eye blink responses were assessed using electromyography. We used ordinary least squares regression adjusted for relevant covariates to model the relationship between prenatal bone lead and PPI. Results: Mean  $\pm$  SD lead concentrations in tibia and patella were  $9.33 \pm 10.00$   $\mu\text{g/g}$ , and  $12.27 \pm 12.17$  respectively. In adjusted models, higher tibia bone lead significantly reduced PPI in children. Patella lead concentrations were independent of PPI. Conclusions: In this population of Mexican children, prenatal tibia lead concentrations were associated with impaired PPI. These results suggest that lead may disrupt PPI, which could be a biological indicator of neurodevelopmental deficits in children.

## **O02.02.27. The Influences of Sociodemographic Characteristics and Changes in Blood Lead on the Concentration-Response Relationship between Blood Lead Level and Children's Intelligence Quotient**

Ellen Kirrane

*Molini M. Patel<sup>1</sup>, Evan Coffman<sup>1</sup>, Jonathan Cohen<sup>2</sup>, Sorina Eftim<sup>2</sup>, Heidi Hubbard<sup>2</sup>, Richard Hornung<sup>3</sup>, Bruce Lanphear<sup>4</sup>, Ellen F. Kirrane<sup>1</sup>*

*4. Simon Fraser University, Burnaby, BC, Canada.*

Abstract: Blood lead levels (BLLs) have decreased over the last several decades but lead exposure remains a risk and the relationship between socioeconomic status, lead, and neurodevelopment is not well-understood. Differences in the distributions of sociodemographic characteristics between children with higher and lower BLLs may account for the nonlinear concentration-response (C-R) relationship observed between BLL and cognitive effects in multiple studies. Specifically, adjustment for sociodemographic characteristics may be an over-adjustment leading to an underestimate of the association at the upper end of the distribution. We analyzed data from the US cohorts examined in the pooled analysis of Lanphear et al. 2005. Like the original analysis, we analyzed relationships of BLL and sociodemographic factors with child IQ using fixed effects multivariable generalized linear regression, and stratified the dataset into children with peak BLLs  $< 7.5$  and  $\geq 7.5$   $\mu\text{g}/\text{dL}$ . Unlike the original analysis we considered the interaction between concurrent BLL and sociodemographic factors and estimated the cumulative impact of BLL and sociodemographic characteristics across the distribution of IQ using quantile regression. The correlation of concurrent BLL with sociodemographic characteristics was generally stronger in the high peak blood lead group, potentially reducing our ability to distinguish the independent effect of blood lead from the effect sociodemographic factors at the upper end of the distribution. The cumulative effect of BLL and sociodemographic factors was largest at the upper end of the IQ distribution in the low peak BLL group suggesting the importance of considering baseline IQ. Overall, this analysis suggests that distribution of sociodemographic factors across the range of BLLs may explain, in part, the attenuation of the C-R relationship at higher BLLs. Disclaimer: Views expressed in abstract are those of authors and do not represent views/policies of the US EPA.

## **002.02.28. A Randomized Controlled Trial to Reduce Childhood Lead Exposure and Lead-Associated Neurobehavioral Deficits: The HOME Study**

Joseph Braun

*Joseph M. Braun<sup>1</sup>, Richard Hornung<sup>2</sup>, Aimin Chen<sup>3</sup>, Kim Dietrich<sup>3</sup>, David Jacobs<sup>4</sup>, Jane Khoury<sup>2</sup>, Stacey Liddy-Hicks<sup>2</sup>, Suzette Vanderbeek<sup>2</sup>, Yingying Xu<sup>2</sup>, Kimberly Yolton<sup>2</sup>, Bruce Lanphear<sup>5</sup>*

- 5. Simon Fraser University, Vancouver, BC, Canada.*

**Abstract:** Background: Childhood lead exposure is associated with neurobehavioral impairments in children. No randomized trials have tested whether a comprehensive residential lead hazard intervention can prevent elevated blood lead concentrations and associated neurobehavioral outcomes. Objectives: We tested whether an intervention designed to reduce residential lead exposure completed during pregnancy could prevent elevated blood lead concentrations and improve neurobehavioral outcomes in children. Methods: We enrolled 355 pregnant women from the Cincinnati, OH metropolitan area in a randomized controlled trial. We randomly assigned women to receive either residential lead or injury hazards. The lead hazard intervention included elements designed to reduce or eliminate lead exposure from paint, drinking water, and soil. We assessed residential dust lead loadings at baseline and when children were ages 1 and 2 years. From ages 1-8 years, we measured blood lead concentrations and assessed cognition, behavior, and executive functions. Results: The intervention reduced floor, windowsill, and window trough dust lead loadings at ages 1 and 2 years by 24% (95% CI: -43, 1), 40% (95% CI: -60, -11), and 47% (95% CI: -68, -10), respectively. The intervention non-significantly reduced children's blood lead concentrations (-6%; 95% CI: -17, 6). Race modified the intervention effect on children's blood lead concentrations (intervention x race p-value=0.03); Black children had greater reductions in blood lead concentrations (-31%; 95% CI: -50, -5) than White children (-2%; 95% CI: -14, 12). Neurobehavioral test scores were subtly better among children in the intervention group than control group; all were statistically non-significant, except for a reduction in anxiety scores (-1.6; 95% CI: -3.2, -0.1). Conclusions: This intervention reduced residential lead exposures and, among Black children, blood lead concentrations, but did not result in substantive neurobehavioral improvements.

## **002.02.29. Urinary Lead Concentration and Its Association with the Composition of the Adult Gut Microbiota**

Shoshannah Eggers

*Shoshannah I. Eggers<sup>1</sup>, Joseph Skarlupka<sup>2</sup>, Ashley Kates<sup>3</sup>, Garret Suen<sup>2</sup>, Paul Peppard<sup>1</sup>, Marty Kanarek<sup>1</sup>, Ajay K. Sethi<sup>1</sup>, Nasia Safdar<sup>3</sup>, Kristen Malecki<sup>1</sup>*

Abstract: Imbalance of the gut microbiota has been linked to many adverse health outcomes including infection, and autoimmune disease. Along with its other detrimental health effects, lead (Pb) exposure may alter the composition of the gut microbiota, but this association has not been investigated in adults. This study examines the association between urinary Pb concentration and the composition of the adult gut microbiota in a non-clinical sample. Data are from the 2016 Survey of the Health of Wisconsin (SHOW) and its ancillary microbiome study. SHOW is a general population-based health survey of Wisconsin residents, collecting survey data on health determinants and outcomes, objective measurements of body habitus, and biological specimens including urine. The ancillary microbiome study collects additional survey data and biological specimens, including stool for microbiota analysis, from participants age 18+. Pb exposure was measured in urine and gut microbiota composition was assessed using 16S rRNA V4 region amplicon sequencing. Statistical analysis includes  $\alpha$  and  $\beta$  diversity metrics, multiple linear regression and PERMANOVA adjusted for relevant confounders, and SIMPER analysis. Of 467 participants, urinary Pb concentration was highest in those age 70+, those with a high school diploma or less, and current smokers. Creatinine adjusted log urinary Pb concentration was associated with a significant decrease in  $\alpha$ -diversity (Shannon  $p= 0.026$ , Inverse-Simpson  $p= 0.051$ ) but not richness, although interactions with age, gender, diet components and smoking status were significant.  $\beta$ -diversity was significantly different between participants in quartile 4 vs. 1 of urinary Pb (Jaccard  $p=0.049$ ), however no operational taxonomic units were significantly different between groups after correction for multiple comparisons. These novel results suggest that Pb exposure is associated with differences in the composition of the adult gut microbiota in a community-based human population.

## 002.02.30. Amyotrophic Lateral Sclerosis and Exposure to Lead in a Danish Cohort

Aisha Dickerson

*Aisha S. Dickerson<sup>1</sup>, Aaron J. Specht<sup>1</sup>, Johnni Hansen<sup>2</sup>, Ole Gredal<sup>2</sup>, Marc Weisskopf<sup>1</sup>*

*1. Harvard T.H. Chan School of Public Health, Boston, MA, United States.*

*2. Danish Cancer Society Research Center, Copenhagen, Denmark.*

**Abstract:** Background: Amyotrophic lateral sclerosis (ALS) is a rare neurodegenerative disorder with rapidly progressive loss of voluntary motor function. Although a recent meta-analysis of occupational exposures and ALS showed a positive association between chronic lead exposure and ALS, results from several studies have yielded conflicting results. Objective: To investigate the association between occupational exposures to lead and odds of ALS. Methods: Utilizing data from a prospective Danish cohort study, we conducted a nested case-control study of occupation and ALS diagnosis. We identified ALS cases from 1982 to 2013 from the Danish National Patient Registry and 100 age- and sex-matched controls per case. Occupation history was obtained from the Danish Pension Fund. We excluded participants with less than 5 years of total work experience and those born more than 25 years before the Pension Fund was established to reduce healthy worker hire bias and exposure misclassification, leaving 1661 ALS cases and 155,169 controls. Cumulative lead exposures were estimated using a job exposure matrix. Adjusted odds ratios (aOR) and 95% confidence intervals (CI) for exposure categories cut at the 30th and 60th percentiles of exposure were obtained using conditional logistic regression analyses and stratified by sex. Results: No significant results were seen in overall cumulative exposures. However, we observed a significant increase in ALS for men with > 50% probability of lead exposure in the highest percentile group during any point prior to the index date (aOR=1.29; 95% CI 1.01, 1.66), 5-year lag (aOR=1.33; 95% CI 1.03, 1.71), and 10-year lag periods (aOR=1.34; 95% CI 1.14, 1.72) compared to those with no exposure. We observed no trends. Conclusion: Our study suggests an association between higher lead levels in men with a high probability of exposure and ALS. These findings support those of previously reported associations between ALS and occupations commonly exposed to lead.

## S02.02A. E-Waste: A Growing Global Problem and Next Steps

### **S02.02.01. An Overview of the Sources and Hazards of E-Waste Exposure on Human Health**

Brittany Trottier

*Brittany Trottier<sup>1</sup>, Michelle Heacock<sup>1</sup>, William Suk<sup>1</sup>*

*1. National Institute of Environmental Health Sciences, Durham, NC, United States.*

Abstract: As the demand for electronics steadily increases throughout the world, the amount of electronic waste (e-waste) accumulates at a rapid pace. Countries such as India, Ghana, China, and Thailand are most impacted by the import and generation of e-waste. E-waste is composed of a combination of hazardous substances including lead, cadmium, chromium and PCBs, that are, by themselves, harmful to human health and contaminate the environment. Direct and indirect exposures to e-waste are a threat to vulnerable groups such as fetuses, children, pregnant women, and the workers in the informal sector that work without personal protective equipment. The majority of e-waste is recycled informally and without personal protective equipment, using primitive techniques such as burning and acid baths, that further exacerbates the exposure to and impact of the hazardous substances to human health. An overview of the health effects resulting from e-waste recycling practices and vulnerable populations associated with informal e-waste recycling will be touched on in this presentation.

## **S02.02.02. Biomonitoring of Female Vietnamese Electronic Waste Recyclers for Selected Metals and Organics**

Linda Birnbaum

*Linda Birnbaum<sup>1</sup>, Arnold N. Schechter<sup>1</sup>, Jiaying Weng<sup>1</sup>, Arnold Strongberg<sup>1</sup>, Jennifer Kincaid<sup>1</sup>*

*1. NIEHS, Research Triangle Park, NC, United States.*

Abstract: Electronic waste (E-waste) has rapidly increased in recent decades, especially in developing nations. Recycling and reclamation of certain chemicals is frequently performed in low and middle income countries including Vietnam where relatively unregulated home based e-waste recycling is common. In 2012, a pilot study was conducted in 2 villages in northern Vietnam, with 10 women who conducted home-based recycling in one and 10 matched controls in another. This was followed in 2013, with a study of 40 recycling women vs 20 non-recyclers. Whole blood, serum, and urine were collected and analyzed at the US Centers for Disease Control for metals, persistent pesticides, PCBs, and both chlorinated and brominated dioxins and furans. PBDEs 47, 99, 100, 153, 154, 183, and 209 were elevated in the recycling women. PCBs 138/158 and 153 were elevated in the younger recyclers. Certain chlorinated dioxins (1,2,3,6,7,8-HxCDD) and furans (1,2,3,6,7,8-HxCDF and 1,2,3,4,6,7,8-HpCDF) as well as 1,2,3,7,8-PeBDD and 2,3,7,8-TBDF were also elevated in the recycling women. Surprisingly, p,p'-DDE was higher in the control women. Lead was elevated in the recycling women, while methyl mercury was higher in the non-recyclers. Of interest, arsenic, methyl mercury, and lead were elevated in both groups of Vietnamese women as compared to women of similar age in the US monitored in NHANES. Further study is indicated to understand not only exposure in a larger group of women doing home recycling, but the potential for adverse health effects from lead, PBDEs, PCBs, and dioxins as all these compounds appear to have neurodevelopmental, endocrine disrupting, carcinogenic, and others in multiple animal species and people. The high levels of arsenic and methyl mercury, as well as lead, in all the northern Vietnamese women is also of concern.

### **S02.02.03. E-Waste Recycling and Exposure Reduction Intervention in the Philippines**

Aimin Chen

*Aimin Chen*<sup>1</sup>

*1. Department of Environmental Health, University of Cincinnati College of Medicine, Cincinnati, OH, United States.*

Abstract: E-waste recycling in the Metro Manila, Philippines, occurs in communities around the metropolitan area. It is usually operated by self-organized recyclers with connection to >2000 junkshops that collect recycled materials. Type of e-waste collected and recycled include cathode ray tube (CRT) TVs, monitors, computers, cell phones, refrigerators, fans, and microwave ovens. The recycling activities performed by thousands of recyclers mostly occur in front of their houses, on the streets, in the backyards, or along the rivers. The recycling activities include manual dismantling, crushing CRTs, burning power cords, and heating circuit boards. There is a lack of pollution control methods to reduce exposure. Limited research in Metro Manila informal e-waste recycling sites suggest increased levels of cadmium, cobalt, copper, manganese, nickel, lead, and zinc in soil samples, similar to findings from other large recycling sites in Asia. Open burning of e-waste also increases polycyclic aromatic hydrocarbon exposure in soil samples. A study in a Metro Manila waste dumping site identified slightly higher polybrominated diphenyl ether concentrations in breast milk compared with a control site. In 2012-2017, Médecins du Monde (Mdm, or Doctors of the World in English), a large non-government organization based in Paris, France, conducted pilot interventions to reduce exposures to e-waste toxicants among informal sector workers. Mdm has mobilized hundreds of informal e-waste recyclers in 4 communities in Metro Manila to form their own Recycler Organizations and conducted multi-prong interventions to mitigate environmental and health hazards. More research is needed to determine the effectiveness of the intervention for chemical hazard reduction.

#### **S02.02.04. Electronic Waste Recycling at Agbogbloshie, Ghana: A Global Problem, Current Intervention Strategies and Local Solutions**

Julius Fobil

*Julius Fobil<sup>1</sup>, Nil Basu<sup>2</sup>, Thomas Robins<sup>3</sup>*

*1. Department of Biological, Environmental & Occupational Health Sciences, University of Ghana School of Public Health, Legon, Accra, Ghana.*

*2. Faculty of Agricultural & Environmental Sciences, McGill University, Montreal, QC, Canada. 3. Department of Environmental Health Sciences, University of Michigan School of Public Health, Ann Arbor, MI, United States.*

**Abstract:** The quantity of electronic waste (e-waste) generated around the globe is expected to increase with rising economies in Asia, Latin America and Eastern Europe largely as a consequence of the introduction of new products with shorter lifespan. Current global estimates of annual e-waste production exceed 40 million tons with an annual growth rate of 4 to 5 percent. However, in spite of the increased generation, there is a current lack of an efficient, safe and sustainable infrastructure for its disposal in many regions of the world; where a majority of the materials in the global e-waste stream ends up as final destination. A typical site in Ghana where the e-waste is received and recycled in an informal setting is the "Agbogbloshie dumpsite" and the lack of appropriate recycling infrastructure has meant that rudimentary and inefficient methods; such as manual dismantling, burning, shredding, melting, and leaching, are applied with resultant significant adverse consequence on human and environmental health. The Agbogbloshie example of e-waste recycling as highlighted in this talk presents the global e-waste production not only as an emerging global health problem, but also as a developing global security issue. More research is therefore needed at the local level to better guide intervention strategies aimed at reducing environmental exposures associated with current recycling methods, while awaiting the development and deployment of acceptable, inexpensive, more efficient and environmentally cleaner technologies.

## S03.04B Exposure and Risk Assessment of Chemicals in Consumer Articles

### **S03.04.06. The European Chemical Industry Guidance on REACH Exposure Assessment Strategies for Substances in Articles**

Tatsiana Dudzina

*Tatsiana Dudzina<sup>1</sup>, Carolyn Lee<sup>1</sup>, Craig Davis<sup>1</sup>, Frank Schnoeder<sup>2</sup>, Alejandro Garabatos<sup>3</sup>, Donna Seid<sup>4</sup>*

- 1. ExxonMobil Biomedical Science Inc., Zaventem, Belgium.*
- 2. DuPont de Nemours (Deutschland) GmbH, Neu-Isenburg, Germany.*
- 3. CEFIC, Brussels, Belgium.*
- 4. Ashland Services B.V., Rotterdam, Netherlands.*

Abstract: Under the European Regulation on Registration, Evaluation and Authorization of Chemicals (REACH) safety assessments of hazardous substances should cover all identified end-uses, including those that lead to the inclusion into articles. Characterization of risks to human health and/or the environment from the subsequent service life cycle stage requires a substantial level of detail on article composition, design, manufacturing process, use patterns under normal reasonably foreseeable conditions, i.e., the information that is not typically available or provided to chemical manufacturers by their downstream users. To overcome this lack of supply chain communication and to ensure consistency in understanding and addressing the problem across all REACH stakeholders, the European Chemical Industry Council (CEFIC) has developed a practical guidance/framework for REACH registrants to help them screen for the necessity of developing exposure scenarios for the service life stage of their substances based on the (limited) information available in the downstream sector use maps. The decision-making framework in the guidance utilizes REACH use description elements such as contributing scenario names, sector of use, and technical function of the substance, as well as the article characteristics known to drive release/exposure potential (e.g. article matrix, shape, intended use pattern). The presentation will outline the decision tree and include introduction to the Release from Articles Potential (RAP) Excel-based tool designed to assist on the determination of a substance's release/emissions based on its technical function in the article. Application of the workflow will be demonstrated with examples for two substances used in the road construction applications and polymer production.

### **S03.04.07. Ranking of Plastic Additives Based on Their Relative Potential for Release from Articles**

Andreas Ahrens

*Andreas Ahrens<sup>1</sup>*

*1. Registration Directorate, European Chemicals Agency, Helsinki, Finland.*

Abstract: The release of hazardous substances from plastic materials is an area of high public interest. During the first two registration deadlines under REACH, several hundred substances potentially used as additives in plastics have been registered in volumes of 100 tonnes/year or more. However, for many of these substances, there is significant uncertainty on the hazards and the potential releases from plastic matrices. In late 2016, ECHA and a number of industry sector organisations have started a joint effort for characterising the uses of the various plastic additives and the corresponding potential for release from articles. This work aims to support i) industry in improving the REACH registration information on the uses of plastic additives and the related exposure potential, and ii) authorities in prioritisation and de-prioritisation of substances for initiation of regulatory processes. The presentation focuses on approaches and learnings from ranking plastic additives: - Data needed to predict the release potential: list of confirmed plastic additives, substance properties determining the release behaviour, additive function and concentration, relevant polymer and article type. - Ranking method: Development of a robust method to compare the release potential of additives from different plastic matrices. - Generation of ranking lists: Grouping of additives by function and ranking according to their release potential. In a subsequent step, the hazard information available for the single additives is combined with their relative release potential, in order to arrive at a risk-based prioritisation and de-prioritisation for regulatory processes. One example for the outcomes of the exercise is the identification of substances i) with significant uncertainties regarding the hazard and ii) having at the same time a high potential for release.

### **S03.04.08. Overview of Approaches to Estimate Consumer Exposure to Articles**

Eva Wong

*Charles Bevington<sup>1</sup>, Zhishi Guo<sup>2</sup>, Xiaoyu Liu<sup>1</sup>, Heidi Hubbard<sup>2</sup>, Eva Wong<sup>1</sup>*

- 1. U.S. EPA, Washington, DC, United States.*
- 2. ICF International, Durham, NC, United States.*

Abstract: Consumer articles can be significant sources of indoor chemical exposures. Exposure estimates can be developed using measured exposure data, modeling approaches, or a combination of both. The U.S. EPA's Office of Pollution Prevention and Toxics (OPPT) has augmented our suite of exposure estimation tools with updates to the Consumer Exposure Model (CEM), the Indoor Environmental Concentrations in Buildings with Conditioned and Unconditioned zones (IECCU) model, and the development of protocols to experimentally determine exposure parameters. OPPT has also completed a second version of indoor exposure testing protocols. The updated protocols have information on experimentally determining the chemical content in products or articles; emission rates, including short- and long term emission rates, material-air partition coefficients; solid phase diffusion coefficients; generation of particles by abrasion; direct transfer of chemical to dust in contact with an article; chemical transformation due to photolysis; migration rates, including chemical migration from an article into water, saliva, and sweat; and dermal exposure to chemicals transferred from liquids or particles to the skin. This presentation will provide an overview of the interrelatedness of consumer exposure models and available empirical data for estimating exposure. This relationship will be shown by providing an example of how CEM and IECCU can be used to estimate exposure to articles using available defaults and how those estimates change when incorporating article and chemical-specific empirical data. The views expressed in this abstract are those of the authors and do not represent Agency policy or endorsement.

### **S03.04.09. Evaluation of Polymers Migration Models**

Hua Qian

*Hua Qian*<sup>1</sup>

*1. Occupational and Public Health Division, ExxonMobil Biomedical Sciences, Inc., Annandale, NJ, United States.*

Abstract: Polymer materials have been widely used as food packages because of various advantages they have including lightweight, durability, easy shape formation etc. During the manufacture process of polymer materials, additives such as antioxidants or colorants may be incorporated to improve the properties of polymers. When the polymer package contact with food, chemicals within Food Contact Materials (FCMs) can have the potential to migrate into food products. Quantifying the migration can help to understand and evaluate consumer's exposure to these chemicals originated from FCMs and ensure the safety of the food at consumption. Besides the laboratory migration testing, various computational models have been developed and used to simulate the chemical diffusion process within FCMs under various conditions. This presentation will provide an overview of the main types of migration models available, their theoretical basis, regulatory applicability in both the US and EU.

### **S03.04.10. Mouthing Exposure Estimation Tool under Canada's Chemicals Management Plan**

Adam Griffiths

*Adam Griffiths<sup>1</sup>*

*1. Health Canada, Ottawa, ON, Canada.*

Abstract: As part of Canada's Chemicals Management Plan, Health Canada assesses exposure to the general population, including vulnerable subpopulations such as children, from industrial chemicals. Children from birth up to 8 years of age are known to be prone to mouthing behaviours, such as sucking, biting and chewing products, which increase their oral exposure to certain contaminants. The presenter will provide an overview of an in silico tool built into Microsoft Access 2010 that allows for rapid estimation of such exposures, providing both exposures (e.g., ug/day) and doses (e.g., ug/kg/day). Thirty-three algorithms, collected from the publicly available literature, are built into the tool, and cover exposures via three pathways: direct object mouthing, swallowing of an object or material, and hand-to-mouth contact. The algorithms are generally not limited to certain chemical classes, and tend to be based on a similar type of equation, consisting of a release rate or concentration, contact rate, exposure duration, and body weight. The tool contains helpful descriptions for each algorithm, including the equation, the assessment tier (e.g., Tier 1, 2), prior use by other agencies, and the reference. In addition to these algorithms, the tool contains recommended upper-bound and central tendency default values for most parameters, for which most are user modifiable. While the tool estimates exposures for one object at a time, multiple algorithms, age groups and substances can be run in batch mode per object. The presenter will describe how the tool can be run, including how to specify scenarios and substance information, how to select applicable algorithms by material and product type, how to input or modify parameter values, and how to use the reporting and export functions. The presenter will also briefly highlight how the tool itself may be modified to suit the program needs of other regulators.

## S02.02C. Monitoring Versus Modeling PM2.5 Concentrations: Does It Matter for Air Pollution Health Effects?

### **S02.02.11. Use of Fine-Resolution AOD-Derived Long-Term PM2.5 Concentrations to Characterize Adverse Health Outcomes**

Joel Schwartz

*Joel D. Schwartz*<sup>1</sup>

*1. Environmental Health, Harvard University, Boston, MA, United States.*

**Abstract:** Remote sensing data from satellites, which can be combined with land use, meteorology, and chemical transport simulations, and trained at monitoring locations, have some distinct advantages over monitoring data in assessing health effects of air pollution. Compared to monitoring data, they can provide fine scale spatial resolution and access to populations not living near monitors; compared to land use regression they can provide fine scale temporal resolution; and compared to inexpensive monitors they can provide better accuracy and historical estimates going back over a decade. I discuss several such models, their performance, and demonstrate how they perform in different studies compared to monitors. In the VIVA birth cohort, an IQR increase in modeled PM2.5 had a stronger association between Impaired Glucose Tolerance (OR=1.64 (1.11, 2.42)) compared to monitored PM2.5 (OR=1.34 (0.98, 1.84)). In the Medicare Mortality cohort they provide somewhat stronger associations between mortality and PM2.5, but much stronger associations with ozone HR= 1.011 (1.010-1.012) Vs 1.001 (1.000-1.002) for 10 ppb. In the New Jersey mortality data they allow differences in differences approach within census tracts that would not be feasible with monitors.

## **S02.02.12. Central Versus Local: Long-Term Exposure to PM2.5, Black Carbon, NO2 and O3 in the European Elapse-Project**

Gerard Hoek

*Gerard Hoek<sup>1</sup>, Bert Brunekreef<sup>1</sup>, Kees de Hoogh<sup>2</sup>*

*1. IRAS, University Utrecht, Utrecht, Netherlands.*

*2. Swiss TPH, Basel, Switzerland.*

**Abstract:** Background: We recently started an analysis of the mortality and morbidity effects of low level air pollution in Europe. The study includes the pooled ESCAPE cohort (11 cohorts across Europe including detailed individual covariate data) and seven large administrative cohorts. This presentation discusses the two methods of exposure assessment for the European ELAPSE study population. Methods: Models were developed for PM2.5, NO2, BC and O3. The first method involves European-wide hybrid land-use regression (LUR) models incorporating routine monitoring data, land-use and traffic data supplemented with satellite observations and dispersion model estimates. The second method consists of local exposure models, including dispersion models and for some cohorts published study-area specific LUR models. Results: The European hybrid model explained a large fraction of measured spatial variation at the European scale. Predictors differed per pollutant. Particularly the PM2.5 model had moderate performance when evaluated with external measurements at the country or smaller scale. Local dispersion models were different in model principle, input data and spatial scale in the various study areas. Conclusions: Strengths and limitations of the two type of models with regard to health effects analyses include harmonization and validity when applied to specific areas.

### **S02.02.13. Using Fused Chemical Transport Models to Estimate Spatially and Temporally Resolved Ambient Air Pollution in Georgia and North Carolina**

Ted Russel

*Ted Russel<sup>1</sup>, Ran Huang<sup>1</sup>, Niru Senthilkumart<sup>1</sup>, James Mulholland<sup>1</sup>, Matthew Strickland<sup>2</sup>, Paige Tobert<sup>3</sup>, Robert Devlin<sup>4</sup>, Lucas Neas<sup>4</sup>, Cavin Ward-Caviness<sup>4</sup>, Wayne Cascio<sup>4</sup>, Howard Chang<sup>3</sup>*

- 1. Civil and Environmental Engineering, Georgia Institute of Technology, Atlanta, GA, United States.*
- 2. University of Nevada, Reno, NV, United States.*
- 3. Emory University, Atlanta, GA, United States.*
- 4. US EPA, Chapel Hill, NC, United States.*

Abstract: A number of adverse health impacts, including acute cardiovascular disease-related events, have been associated with exposure to fine particulate matter (e.g., PM<sub>2.5</sub>). Given the prevalence of data for PM<sub>2.5</sub> mass concentrations, most of these studies are based upon total PM<sub>2.5</sub> mass, not on individual species. However, a number of studies have found differing associations of disease outcomes with PM<sub>2.5</sub> components (or species), and PM properties (e.g., size and oxidative potential: OP). Data assimilation using chemical transport modelling (CMAQ) and observations is used to develop concentration fields of major PM<sub>2.5</sub> components for two areas: Georgia and North Carolina. As part of a cohort study of birthweight, speciated PM<sub>2.5</sub> and gaseous pollutant fields were constructed over Georgia for 2002-2006. Increases in air pollutant concentrations were associated with decreases in mean birth weight. In this study, speciated PM fields are also constructed over North Carolina for 2002-2009 studying patients who had undergone a cardiac catheterization in North Carolina. As part of a comparison of approaches, the model-observation fusing approach used here for PM<sub>2.5</sub>, performance was similar to using a method including satellite data as well as more coarse resolution modelling and provided speciated PM<sub>2.5</sub> fields as well as gaseous pollutants that are not as readily observed using remote sensing methods, or where such observations are temporally constrained. Speciated spatiotemporal fields developed here include elemental and organic carbon (EC/OC), sulfate, nitrate, ammonium, and crustal material. The CMAQ approach also provides NO<sub>x</sub>, O<sub>3</sub> and CO fields, and can also estimate additional properties such as aerosol pH and oxidative potential. While this work was funded, in part, by the US EPA, this abstract does not necessarily reflect EPA policy.

## **S02.02.14. Mortality Effects of Ambient Fine Particulate Matter Estimated Using Ground-Based Versus Remote Sensing Exposure Estimates**

Michael Jerrett

*Michael Jerrett<sup>1</sup>, Michelle C. Turner<sup>2</sup>, Daniel Krewski<sup>3</sup>, Randall Martin<sup>4</sup>, Rick Burnett<sup>5</sup>*

*1. Environmental Health Sciences, UCLA, Santa Monica, CA, United States.*

*2. ISGlobal, Barcelona, Spain.*

*3. University of Ottawa, Ottawa, ON, Canada.*

*4. Dalhousie University, Halifax, NS, Canada.*

*5. Health Canada, Ottawa, ON, Canada.*

**Abstract:** Background: Remote sensing (RS) is increasingly used for exposure assessment in epidemiological and burden of disease studies, including those investigating whether chronic exposure to ambient fine particulate matter (PM<sub>2.5</sub>) is associated with mortality. Objectives: To compare relative risk estimates of mortality from diseases of the circulatory system for PM<sub>2.5</sub> modeled from RS with that for PM<sub>2.5</sub> modeled using ground-level information and atmospheric chemistry models. Methods: We geocoded the baseline residence of 668,629 American Cancer Society Cancer Prevention Study II (CPS-II) cohort participants followed from 1982 to 2004 and assigned PM<sub>2.5</sub> levels to all participants using seven different exposure models. Most of the exposure models were averaged for the years 2002-2004, while one RS estimate was for a longer, contemporaneous period. We used Cox proportional hazards regression to estimate relative risks (RR) for the association of PM<sub>2.5</sub> with mortality from circulatory and from ischemic heart disease. Results: Estimates of mortality risk differed among exposure models. The smallest relative risk was observed for the RS estimates that excluded ground-based monitors for circulatory deaths (RR = 1.02 (95% confidence interval (CI): 1.00-1.04 per 10 µg/m<sup>3</sup> increment in PM<sub>2.5</sub>). The largest relative risk was observed for the land use regression model that included traffic information (RR = 1.14, 95% CI: 1.11-1.17 per 10 µg/m<sup>3</sup> increment in PM<sub>2.5</sub>). Conclusions: We found significant associations between PM<sub>2.5</sub> and mortality in every model; however, relative risks estimated from exposure models using ground-based information were generally larger than those estimated with RS alone. When all seven estimates were pooled, the estimates using ground-level information dominated the pooled estimate.

## **S02.02.15. Comparison of Long-Term PM<sub>2.5</sub> Concentrations from Ground-Based Monitoring, CMAQ Models and Satellite-Derived AOD to Characterize Adverse Cardiovascular Outcomes**

Laura McGuinn

*Laura McGuinn<sup>1</sup>, Alexandra E. Schneider<sup>2</sup>, Cavin Ward-Caviness<sup>3</sup>, Qian Di<sup>4</sup>, Joel D. Schwartz<sup>4</sup>, Armistead Russell<sup>5</sup>, Elizabeth Hauser<sup>6</sup>, William Kraus<sup>6</sup>, Lucas Neas<sup>3</sup>, Wayne Cascio<sup>3</sup>, David Diaz-Sanchez<sup>3</sup>, Robert Devlin<sup>3</sup>*

- 1. University of North Carolina at Chapel Hill, Chapel Hill , NC, United States.*
- 2. Institute of Epidemiology II, Helmholtz Zentrum München - German Research Center for Environmental Health, Neuherberg, Germany.*

- 4. Harvard T.H. Chan School of Public Health, Boston, MA, United States.*
- 5. Georgia Institute of Technology, Atlanta, GA, United States.*
- 6. Duke University Medical Center, Durham, NC, United States.*

**Abstract:** Background: Adverse cardiovascular events have been linked with particulate matter <2.5 µm (PM<sub>2.5</sub>) exposure obtained primarily from air quality monitors, which rarely co-locate with participant residences. Modeled PM<sub>2.5</sub> predictions at finer resolution may more accurately predict residential exposure, though few studies have compared results across different exposure assessment methods. Methods: We utilized a cohort of 5679 patients who had undergone a cardiac catheterization between 2002-2009 and resided in North Carolina. Exposure to PM<sub>2.5</sub> for the year prior to catheterization was estimated using data from air quality monitors, Community Multiscale Air Quality (CMAQ) fused models at the census tract and 12km spatial resolutions, and satellite-based models at 10km and 1km resolutions. The coronary artery disease (CAD) index was used to measure severity of CAD, and individuals with an index >23 were considered positive cases with hemodynamically significant lesions. Separate models were constructed for each exposure metric, and logistic regression was used to model odds of having CAD or a recent myocardial infarction (MI) with each 1-µg/m<sup>3</sup> increase in PM<sub>2.5</sub>, adjusting for sex, race, smoking status, socioeconomic status, and urban/rural status. Results: Correlations between exposure metrics ranged from 0.6 to 0.9 and mean annual average PM<sub>2.5</sub> levels ranged from 12.3 to 12.8 µg/m<sup>3</sup>. Interquartile ranges varied across metrics with an IQR of 0.8 for 10km-satellite models and 1.3 for 1km-satellite models. The elevated odds for CAD>23 and MI ranged across exposure metrics, with a CAD odds ratio of 1.04 (95%CI: 0.99, 1.10) for monitored data and 1.13 (95%CI: 1.06, 1.21) for 10km-satellite data. Results differed by urban/rural status when using the monitored and census tract-CMAQ metrics. Conclusions: Long-term air pollution exposure was associated with coronary artery disease for both modeled and monitored data. This abstract does not necessarily represent EPA policy.

S02.02D. Opportunity to Accelerate Knowledge on Complex Developmental Chemical Exposures and Child Health: Environmental Influences on Child Health Outcomes (ECHO)

**S02.02.16. Accelerating Research on Chemical Exposures and Child Health Outcomes through ECHO: An Overview**

Jessie Buckley

*Jessie Buckley<sup>1</sup>, Tracey Woodruff<sup>2</sup>*

*1. Environmental Health & Engineering, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States.*

*2. Program on Reproductive Health and the Environment, University of California, San Francisco, San Francisco, CA, United States.*

**Abstract:** Background: The Environmental Influences on Child Health Outcomes (ECHO) program is a seven-year U.S. National Institutes of Health initiative launched in 2016 to advance knowledge of the effects of a broad range of environmental exposures on child health and development. Objective: To provide an overview of the ECHO program as it relates to understanding relationships between early life chemical exposures and child health outcomes. Methods: We overview ongoing efforts related to chemical exposures and child health outcomes in ECHO by describing existing chemical exposure information and plans for new data collection. Results: ECHO's observational component leverages data from 84 extant longitudinal cohorts with more than 50,000 children from diverse backgrounds across 44 states, Puerto Rico, and the District of Columbia. The earliest cohort enrolled participants beginning in the 1980s while others have ongoing enrollment. Most cohorts began recruitment during gestation and all cohorts follow children longitudinally and collect biospecimens. ECHO includes working groups dedicated to chemical exposures as well as five outcome focus areas: 1) pre-, peri- and postnatal outcomes; 2) obesity and its consequences; 3) upper and lower airway conditions; 4) neurodevelopment; and 5) positive health. Existing chemical exposures data already collected by some ECHO cohorts includes chemical biomonitoring data, estimates of outdoor air pollution or geographic proxies of air pollution, environmental or personal exposure monitoring, and questionnaire data. In addition, all ECHO cohorts will contribute certain existing and new data as part of the ECHO-wide Cohort data collection protocol, including biospecimens and exposure questionnaires at key life stages of development. Conclusion: By combining rich, longitudinal data with team science approaches, ECHO will accelerate novel and policy-oriented research to address complex environmental health questions.

## **S02.02.17. Leveraging Variability across Space and Time to Assess Air Pollution Exposures and Child Health in ECHO**

**Abstract:** Background: Air pollution exposure is ubiquitous with demonstrated effects on morbidity and mortality. A more recent, growing literature suggests that prenatal air pollution exposure affects neurodevelopment. Objective: We describe current methods for air pollution exposure assessment, summarize existing studies of air pollution and neurodevelopment, and synthesize this information as a basis for recommendations, or a blueprint, for evaluating air pollution effects on neurodevelopmental outcomes in ECHO. Methods: We review peer-reviewed literature on prenatal air pollution exposure and neurodevelopmental outcomes, including autism spectrum disorder, attention deficit hyperactivity disorder, intelligence, general cognition, mood, and imaging measures. We compiled and evaluated cohort data to assess frequency of neurodevelopmental assessments and prenatal and infancy residential address locations. Cohort recruitment locations and enrollment years were summarized to examine potential spatial and temporal variation present in ECHO. Results: While the literature broadly suggests that prenatal air pollution effects neurodevelopment, limitations in spatial and temporal exposure variation exist for current published studies. Additionally, current sample sizes do not allow for well-powered investigations of mixtures, effect modification, or evaluation of windows of susceptibility to exposure. As over 90% of the ECHO cohorts have collected a prenatal or infancy (birth to 12 months) address, with the majority of recruitment spanning the last 20 years, application of advanced geographic information systems (GIS) based models for common air pollutant exposures may be ideal to address limitations of published research. Conclusions: In ECHO we have the opportunity to pioneer unifying exposure assessment and evaluate effects across multiple neurodevelopmental outcomes, setting the standard for evaluation of prenatal air pollution exposures with the goal of improving children's health.

## **S02.02.18. Mapping Chemicals across Routes of Exposure and Body Burden: Data Gaps and Opportunities for ECHO**

**Abstract:** Background: Tens of thousands of chemicals are used in the U.S.; however, there is a paucity of information on the impact of these agents on children's health. Biomonitoring can permit an assessment of exposure through multiple routes; but only when methods are available. Objective: We postulate that published literature, government databases, and other sources contain understudied chemicals that may impact health outcomes of interest in ECHO. Methods: We developed a list of chemicals occurring in environment media from industrial processes and/or found in consumer products to which mothers and children could be exposed and which have the potential for toxicity. We gathered additional information on these compounds through a semi-structured review of peer-reviewed literature and several governmental databases. Factors being considered include: (a) likelihood of exposures based upon the level and frequency of detection in environmental media, (b) levels previously found in human biofluids, (c) predicted exposures from using consumer products, and (d) toxic potency, from published in vivo and in vitro test results, from priority lists of hazardous chemicals, and from predictive toxicity modeling. Results: We used a framework to evaluate the varied data for the numerous compounds to categorize and rank compounds as to the potential level of concern. The resulting categories are 1) compounds recommended for inclusion in ECHO 2) compounds for which we encourage more toxicological or exposure data to be generated, and 3) the use of untargeted assays in select subpopulations to evaluate feasibility of quantifying emergent and unknown chemicals/metabolites as biomarkers. Conclusions: We anticipate that expanding the compounds included in studies such as ECHO will increase the probability of finding chemicals potentially associated with adverse health effects in children.

**Abstract:** Background: Environmental Influences on Child Health Outcomes (ECHO) is an NIH program linking 84 existing longitudinal cohorts of more than 50,000 children from across the US to understand effects of environmental influences on child health and development. ECHO represents an unprecedented opportunity to improve our understanding of developmental chemical exposures and during childhood and their associations with a range of adverse health outcomes. Objective: We reviewed current chemical exposure data available in ECHO and provided a framework for identifying and informing future research activities. We surveyed the ECHO cohorts to collect information on cohort measurements of chemical exposure through biomonitoring. We developed a framework to prioritize current and future research. Results and Discussion: Out of the 84 cohorts in ECHO, about 60% have existing or planned chemical biomonitoring data. More than a dozen classes of chemicals are being measured. The chemicals most frequently being measured are biomarkers of tobacco, environmental phenols, and phthalates. A smaller proportion of cohorts are measuring metals, PBDEs, PCBs, PAHs, organochlorine pesticides, or organophosphate pesticides. Only a handful are measuring perfluorinated compounds, pyrethroids, perchlorate, or disinfection byproducts. Most of the chemicals are measured prenatally or at delivery, with fewer cohorts measuring chemicals during childhood; a few cohorts measure preconception and paternal biomarkers. ECHO outcome focus areas include pregnancy outcomes, respiratory health, neurodevelopment, and obesity. We propose five categories of priorities for biomonitoring which consider the degree of current scientific information on chemical health effects, opportunities for new discovery, and the extent of health concern among the public given historical bans/phase outs. We will present our priorities for current and future chemical analysis to leverage this rich cohort to advance child health.

## **S02.02.20. Accessing ECHO Data to Address Innovative Hypotheses**

Jessie Buckley

*Jessie Buckley<sup>1</sup>, Tracey Woodruff<sup>2</sup>*

*1. Department of Environmental Health & Engineering, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States.*

*2. Program on Reproductive Health and the Environment, University of California, San Francisco, San Francisco, CA, United States.*

**Abstract:** Background: The Environmental Influences on Child Health Outcomes (ECHO) program will establish a national data resource platform with which scientists can address a wide variety of research questions about the etiology or prediction of child health outcomes. Objective: To discuss ECHO's publications policies and future opportunities for the general environmental health sciences community to access ECHO data. Discussion: ECHO's Publications Committee has established policies regarding the development and review of research products that include data or investigators from more than one ECHO awardee. The first step for investigators wishing to initiate a research product is to submit an Analysis Concept proposal. These proposals are initiated by writing teams, which can include researchers within or outside the ECHO program. Analysis concept proposals related to chemical exposures may utilize extant data or propose new biomonitoring utilizing stored biospecimens. Analysis Concepts are circulated to the ECHO scientific community with the goal of soliciting input on the scientific aims and additional writing team members. Next, the writing team develops and submits an Analysis Proposal with input from ECHO's Data Analysis Center. The Analysis Proposal is submitted to the Publications Committee for review and then evaluated by the ECHO Steering Committee for final approval. Additional information on current procedures and timelines for data access by non-ECHO investigators will be described, followed by a question and answer session.

## S02.02E. Solutions for Tackling the Link between Complex Exposures and Human Health

### S02.02.21. Simplicity in Complex Environmental Health Problems Using the Exposome

Dimosthenis Sarigiannis

*Dimosthenis A. Sarigiannis<sup>1</sup>*

*1. Chemical Engineering, Aristotle University of Thessaloniki, Thessaloniki, Greece.*

Abstract: Simplicity in environmental health warrants finding simple solutions while embracing the complexity in the links between multiple and complex environmental exposures and human health responses. It requires integration of multiple datasets, bringing together big data analytics with high dimension systems biology and advanced epidemiological analysis. The objective is to support the development of precision prevention strategies that protect public health while ensuring cost-effectiveness and addressing environmental health inequities. This is greatly facilitated by the advent of new high throughput analytical and multi-sensing methods supporting their coming together in the quest to create the premise for delivering precision medicine. Even though this is a true revolution for the promotion of good health and cost-effective healthcare on the individual level, public health promotion warrants paying equal attention to prevention and avoidance/reduction of human exposure to the stressors that contribute to ill health. The exposome, the totality of exposures over one's lifetime, and the genome are the two main determinants of human health. Effectively coupling genetic information with environmental and exposure-related data, as well as capturing epigenetic perturbations and linking them with mechanisms of toxicity and adverse outcome pathways maybe the solution towards the development of efficient environmental policies that protect both the quality of the environment, ecosystem function and human health. Unlike the traditional environmental epidemiology paradigm, computational exposure biology and exposome-wide association studies embrace all factors that determine or modulate human health and its interaction with the exposome. Pre-existing health conditions, prior exposures or deleterious habits such as smoking, but also age, gender, socio-economic status are considered part of an individual's exposome. This paves the way towards effective precision prevention policy.

## **S02.02.22. Lifelong Exposure of Population Subgroups with PM2.5**

Naixin Li

*Naixin Li<sup>1</sup>, Rainer Friedrich<sup>1</sup>, Christian Schieberle<sup>1</sup>*

*1. TFU, IER University Stuttgart, Stuttgart, Germany.*

Abstract: Fine particulate matter (PM2.5) is one of the mostly concerned air pollutants that are associated with premature mortality and other diseases. Existing studies mainly focus on assessing exposure to PM2.5 for a short period of time; however the health status of persons is influenced by long-term exposure over life course. To support the health impact assessment, we developed and applied a probabilistic model to estimate the temporal course of the external exposure to PM2.5 for persons that are characterized by certain features (e.g. age, gender, employment status, income). The annual average background concentration fields for Europe since 1930s are generated and applied as input data for PM2.5 concentration modelling for different microenvironments. Other parameters for concentration simulation include indoor sources, physical factors (e.g. ventilation rate, decay rate) and enrichment factor for traffic. Data of time activity pattern from MTUS are utilized to simulate the time-weighted average exposure for each year. The results of annual exposure are applied in a life trajectory model to assess the lifelong exposure to PM2.5. This methodology is applied to population samples from EU-SILC data. The concentration modelling for residential microenvironment is evaluated with measurement data from EXPOLIS study. 70% of the samples are within the range of 25th to 75th percentile of the modelling distributions. Exposure to PM2.5 varies substantially among population living in different countries and time periods. The influences of socioeconomic variables including income and employment status are noted as well. Penetration from outdoor is one of the most important sources, while exposure from other sources is affected by population behavioral patterns (e.g. smoking habits, use of wood stove). Installation of advanced ventilation system is revealed effective in decreasing indoor concentration level.

## **S02.02.23. Integrated Use of Agent Based Modelling (ABM) with Wearable Sensors for Personal Exposure Assessment**

Dimitris Chapizanis

*Dimitris Chapizanis<sup>1</sup>, Spyros Karakitsios<sup>1</sup>, Dimosthenis A. Sarigiannis<sup>1</sup>*

*1. Environmental Engineering Laboratory, Department of Chemical Engineering, Aristotle University of Thessaloniki, Thessaloniki, Greece.*

**Abstract:** Considering the substantial hurdles involved in collecting individual data for whole populations, this study introduces a first approach of simulating human movement and interaction behaviour, using Agent Based Modelling (ABM). A city scale ABM was developed for the urban area of Thessaloniki, Greece. The model feeds into population-based exposure assessment, basing its estimations onto emerging behaviours of all the heterogeneous entities (agents) that compose the city-system. Population statistics, road and buildings networks data were transformed into human, road and building agents respectively. Time-use survey outputs and personal sensor collected data were associated with human agent rules, aiming to model representative to real-world routines. In addition, time-geography of exposure data, derived from a personal sensors campaign on 100 households, was used to inform the model. As a prevalence of an agent-specific decision-making, virtual individuals of different sociodemographic backgrounds express different spatiotemporal behaviours and their trajectories are coupled with spatially resolved pollution levels. Personal exposure was evaluated by assigning PM<sub>2.5</sub> concentrations to human agents based on coordinates, type of location and intensity of encountered activities. Study results indicated that PM<sub>2.5</sub> inhalation adjusted exposure between housemates can differ by 32% whereas exposure between two neighbours can vary by as much as 77%, due to the prevalence of different behaviours. This approach permits the cost-effective construction of time-activity diaries and daily exposure profiles, considering different microenvironments and socioeconomic characteristics. The proposed method leads to a refined exposure assessment model, addressing effectively vulnerable subgroups of population. It can serve as a tool to evaluate probable impacts of public health policies prior to implementation, reducing the time and cost required to identify effective measures.

## **S02.02.24. Unraveling the Complex Etiology of Neurodevelopmental Disorders: Tools, Key Issues and Research Needs to Investigate the Environmental Contribution**

Gemma Calamandrei

*Gemma Calamandrei<sup>1</sup>, Flavia Chiarotti<sup>1</sup>, AnnaMaria Tartaglione<sup>1</sup>, Laura Ricceri<sup>1</sup>, Ettore Meccia<sup>2</sup>, Kinga Polanska<sup>3</sup>, Denis Sarigiannis<sup>4</sup>*

- 2. Department of Environment and Health, Istituto Superiore di Sanità, Rome, Italy.*
- 3. Nofer Institute of Occupational Medicine, Lodz, Poland.*
- 4. Aristotle University of Thessaloniki, Thessaloniki, Greece.*

"Abstract: Events occurring in the earliest stages of human development may influence both resilience and vulnerability to later neuropsychiatric/neurologic disorders. Research in animals has shown that diverse environmental stressors may interfere with typical brain development in critical time windows, inducing silent sub-clinical alterations that may hesitate in behavioral alterations at later life stages. Epidemiological prospective studies have in many cases supported the link between sub-toxic exposure to chemical pollutants and neurobehavioral effects in children. Recent advances in research offer important clues into the complex etiology of autism and other neurodevelopmental disorders (NDDs). The convergence of risk factors on the same cell/molecular pathways combined with a vulnerable gene makeup would trigger the development of the disorders or predispose to adverse outcome later on. The exposomic approach may help unraveling this complex etiology through characterization/quantification of exogenous and endogenous exposures and modifiable risk factors for NDDs. A critical issue is validation of peripheral biomarkers of effects that can inform on typical and atypical brain development, and establish biologically plausible links between chemicals and health effects in humans. Laboratory studies might contribute by modeling in "simpler" living organisms and systems the complexity of the human exposure scenarios. This would also entail the discovery of "omic" signatures anchored to the behavioral phenotype. Targeted in vivo studies will possibly empower the human exposome with peripheral accessible markers of susceptibility, vulnerability and effects, mirroring the effects in brain and able to predict the behavioral outcomes of developmental exposure to neurotoxicants and endocrine-disrupting chemicals. This integrated approach is being applied to establish the link between environmental stressors and child neuropsychological health in some European birth cohorts. "

## **S02.02.25. Use of Exposome to Explain the Allergy Epidemics**

Isabella Annesi-Maesano

*Isabella Annesi-Maesano<sup>1</sup>*

*1. EPAR IPLESP, INSERM & Sorbonne Université, Paris, France.*

Abstract: Worldwide, up to 50% of individuals will suffer from at least one allergy by 2050 due to environmental changes. Although daunting, proof of concept studies are being conducted that show the promise of the exposomic investigation and integration of different kinds of data to explain the allergy epidemics; the exposome being the totality of external environmental exposures (external exposome) to which an individual is exposed in life and their consequences in the body (internal exposome). The specific external exposome acting on allergic diseases include indoor and outdoor aeroallergens and chemical air pollutants. To it has to be added non-specific external exposome, namely the action of climate change, urbanization and loss of biodiversity that affect sources, emissions and concentrations of main aeroallergens and chemical air pollutants. In this context, thunderstorm-related asthma is a dramatic example of the effects of combined environmental factors and an in vivo model for understanding the mechanisms at work in respiratory allergy. In terms of internal exposome, environment- or lifestyle-driven aberrancies in the gut and skin microbiome composition represent a key mediator of allergic diseases. In addition, the role of epigenetic mechanisms (particularly DNA methylation) in allergic disease is also considered in the implementation of the exposome because these mechanisms are known to be at the interface among gene regulation, environmental stimuli and developmental processes, all of which are essential for the pathogenesis for asthma and allergies. Tools and methods to implement the external and internal exposome (sensors, geographic information systems, and ad hoc survey instruments) will be presented. A better knowledge of the impact of the exposome on allergy development is crucial for urging individuals, health professionals and policy makers to take actions to mitigate the effect of environmental changes and to adapt to them.

## S02.02F. The Complexity of Microbiomes for Exposure Science

### **S02.02.27. The Built Environment: Why Understanding Microbiology Matters**

Erica Hartmann

*Erica M. Hartmann<sup>1</sup>*

*1. Civil and Environmental Engineering, Northwestern University, Evanston, IL, United States.*

Abstract: We live and work largely indoors and share our indoor environments with an array of microorganisms and microbial products. The microbial communities found in buildings are influenced by a number of factors, including ventilation, humidity, and chemistry, and we help shape these microbiomes through choices about the design, construction, operation, occupancy, and use of our built environments. There has long been interest in how our indoor environments affect health positively or negatively, for example, in the transmission of infectious diseases or in the development of allergic and respiratory symptoms. Research has begun to offer insights into the characteristics of indoor microbial communities-not just which microbes are present but also what they are capable of, particularly with regard to antibiotic resistance-and how these can be affected by interventions. However, what characterizes a "healthy" indoor environment remains largely undefined. The presentation will illustrate examples of recent findings and highlight multidisciplinary collaborative efforts that increase our understanding of these issues. It will provide a perspective on why research that connects microbial ecology, architecture, and environmental and public health will improve the evaluation of how interactions between the built environment and its microbiomes affect us and contribute to a fuller understanding of exposures and health with the long-term aim of improving building design for more healthful environments in the future.

## **S02.02.28. Microbiome Metabolism and Chemical Transformation: How Does the Human Microbiome Change Our Chemical Exposures?**

Andrew Patterson

*Andrew Patterson*<sup>1</sup>

*1. Penn State University, University Park, PA, United States.*

Abstract: The fields of toxicology and xenobiotic metabolism have long recognized the beneficial and sometimes deleterious influence of microbiota in the absorption, distribution, metabolism, and excretion of drugs and toxicants. Early pioneering work with the antibacterial drug prontosil pointed towards the necessity to not only understand the metabolic capabilities of the microbiota but to identify the specific microbiota involved in the generation and metabolism of xenobiotics. However, technological limitations important for cataloging the microbiota community and for understanding or predicting their metabolic capabilities hindered progress. Current advances, including mass spectrometry-based metabolite profiling and culture-independent sequence-based identification and functional analysis of microbiota, have begun to shed light on microbial metabolism. Case studies will be presented to highlight key aspects—for example, microbiota identification, metabolic function and prediction, metabolite identification and profiling—that have helped clarify how microbiota might affect or be affected by xenobiotic metabolism. Lastly, a perspective of the future of this field is presented taking into account what important knowledge is lacking and how to tackle these problems with respect to informing exposure, human health, and disease risk.

## **S02.02.29. The Possible Consequences of Ignoring the Human Microbiome in Health Risk Assessment**

Joseph Rodricks

*Joseph Rodricks<sup>1</sup>*

*1. RAMBOLL, Arlington, VA, United States.*

Abstract: Emerging research has shown that the microbiome can influence chemical metabolism and absorption and that chemical exposures can perturb microbiome composition and function. Although this research has clear implications for the assessment of human health risks from chemical exposures, risk assessments have not typically incorporated considerations of the human microbiome. Proper characterization of microbial exposures to chemicals would enhance the assessment process. The exposure science community has been relatively silent on chemical-microbiome interactions and their effects on exposure and ultimately risk. As noted in a recent report of the National Academies of Sciences, Engineering, and Medicine, "there is a need to expand the scope of exposure science to incorporate the emerging understanding of the roles of the human microbiome as an agent that influences exposure to and risks posed by environmental chemicals." Examples will be presented to illustrate how the microbiome might modulate the exposure of health risks posed by several environmental chemicals. Major microbiome sites - gut, skin, and respiratory tract - will be highlighted. Opportunities and challenges that might arise in integrating microbiome considerations into exposure science and risk assessment will be discussed.

S02.02G. The Fluoridation Decision: Considering the Evidence for Benefits, Possible Risks as Well as Ethical World Views

**S02.02.31. Ethical World Views and Fluoridation Policy**

Raymond Neutra

*Raymond R. Neutra<sup>1</sup>*

*1. Div. Env. and Occup. Disease Control, CA Dept of Public Health (Retired), Pacific Grove, CA, United States.*

Abstract: A utilitarian world view favors a policy where the accumulated utility from benefits outweighs the disutility of any adverse side effects. A Libertarian Duty Ethics world view opposes any policy that threatens any individual's autonomy. The Libertarian perspective may become more salient if possible adverse effects were found to convey higher risks to vulnerable persons with certain genes. What policies might address both world views?

## **S02.02.32. Evidence About the Benefits of Fluoridation: Caries Prevention Benefits**

E. Martinez-Mier

*E. A. Martinez-Mier<sup>1</sup>*

*1. Cariology, Operative Dentistry and Dental Public Health, Indiana University School of Dentistry, Indianapolis, IN, United States.*

Abstract: At appropriate levels, fluoride has been well established as a safe and effective agent in the prevention of dental caries. On the other hand, when individuals are exposed to excessive amounts of fluoride, negative side effects are seen. Despite advances in the reduction of oral diseases, dental caries remains common among both children and adults worldwide, especially among underserved populations in high, middle, and low income countries. Dental caries can negatively affect individuals' overall health and quality of life, and often results in reduced productivity. In addition, its traditional treatment is extremely costly, in both high and low-income countries. While death as a direct result of dental caries remains rare, its presence does result in years lived with disability. This presentation will review the evidence supporting fluoride's role in lowering the prevalence and incidence of dental caries and the preservation of functional dentition as well as good nutrition in late adulthood and how this results in increasing disability-adjusted life years (DALYs). Findings from selected studies on global and national incidence, prevalence, and years lived with disability for dental caries will be reviewed. Trends on the prevalence of dental caries in different segments of the population as well as the number of people with untreated disease will also be presented. The detailed analysis of this evidence will provide background information for an informed discussion on the benefits of fluoridation and any diminution of DALYs from potential adverse side effects.

### **S02.02.33. Neurotoxic Effects of Fluoride Exposures in North America**

Christine Till

*Christine Till<sup>1</sup>*

*1. Psychology, York University, Toronto, ON, Canada.*

Abstract: Fluoride is neurotoxic at exposure levels that exceed maximum intake levels, but less is known about the neurotoxicity of fluoride at 'optimal' levels. Concerns about community fluoridation schemes and adverse health effects are steadily mounting, particularly for vulnerable populations, such as the fetus and young children. There is also concern that the prevalence and severity of dental enamel fluorosis have increased over the past three decades among youth in Canada and the United States. These findings suggest that a fraction of the population experiences excessive intake of fluoride in early development. In 2006, the National Research Council concluded that developmental neurotoxicity may be associated with fluoride exposures given the consistency of available evidence from animal and human studies. However, it has been a public health challenge to reach scientific consensus about what constitutes a safe level of fluoride. This is partly due to the lack of rigorous scientific investigations examining fluoride exposure at critical periods in development and using sensitive endpoints and effective biomarkers of exposure. This presentation reviews recent epidemiologic studies that help to fill in the gap related to detrimental health consequences related to water or salt fluoridation programs. Findings reported in a Canadian and Mexican birth cohort are consistent in showing that higher level of urinary fluoride in pregnancy is associated with lower IQ in offspring. Other adverse effects of fluoride exposure include increased risk of attention deficits following prenatal exposure to fluoride and increased risk of thyroid disruption among iodine-deficient adults. This growing body of evidence linking chronic fluoride exposure to serious health risks beyond fluorosis adds critical new information to the evidence base for informing public health policy.

## **S02.02.34. Possible Benefits and Adverse Effects of Fluoridation in England, 2018 Public Health England Report**

Tony Fletcher

*Tony Fletcher<sup>1</sup>, Giovanni S. Leonardi<sup>1</sup>, David Roberts<sup>1</sup>*

*1. CEE, Public Health England, Chilton, United Kingdom.*

**Abstract:** The protective effect of community water fluoridation (CWF) on caries has been well demonstrated and relationships with adverse health outcomes have also been alleged. We have recently completed a study of the association between concentrations of fluoride in public water supplies (PWS) and dental caries indicators, as well as several adverse non-dental health-outcomes in England, using recent available routine surveillance data. The methods and results are presented in more detail in other talks at this meeting. The benefits in terms on reduction of caries from CWF are clearly supported by our results, and there was strong interaction with socio-economic status. For example, comparing children in areas with a fluoridation scheme and >0.7mg/l fluoride to low areas with <0.2mg/l fluoride, there are 17% less with caries in the least deprived areas, rising to 28% in the most deprived areas. For non-dental outcomes, we found some associations between fluoride and fractures (adverse) and bladder cancer (protective). However in both cases the pattern of results, especially the lack of a dose response pattern across exposure, suggested a non-causal association. It was concluded that these findings were consistent with water fluoridation being an effective and safe public health measure, in areas with fluoride concentration up to 1 mg/l, to reduce dental caries and reduce dental health inequalities. In reaching this conclusion, the study team balanced both the magnitude of the dental and non-dental effects, and the strength of evidence in terms of internal coherence and consistency with other evidence. Most studies showing adverse effects are at much higher fluoride concentrations and extrapolation to lower concentrations is very uncertain. Some endpoints such as endocrine (thyroid) and neurological (IQ) for exposure up to 1 mg/l could not be addressed in this study, and still need addressing.

## S02.02H. Exploring Current Worker Exposure Tools and their Capability to Support Risk Evaluations of Chemicals Under Amended TSCA

### **S02.02.36. Overview of EPA's Occupational Exposure Tools and Approaches Used in New and Existing Chemical Evaluations Under Amended TSCA**

Nhan Nguyen

*Nhan T. Nguyen<sup>1</sup>*

*1. US EPA, DC, DC, United States.*

Abstract: On June 22, 2016, the Frank R. Lautenberg Chemical Safety for the 21st Century Act was signed into law amending the Toxic Substances Control Act (TSCA), the Nation's primary chemicals management law. The Office of Pollution Prevention and Toxics (OPPT's) risk evaluation addresses occupational settings as part of the exposure assessment. Release to the environment and occupational exposures may be considered simultaneously to gain assessment efficiencies. Key exposure parameters include duration, intensity, frequency and number of workers exposed under the conditions of use of a chemical, and key release parameters may be expressed similarly. Typically, measured data are preferred, but when data are not available, empirical and modeling approaches or assumptions are used. This presentation provides an overview of OPPT's approaches and tools used for assessing occupational exposures and releases of new and existing chemicals with a focus on EPA's computerized tool called Chemical Screening Tool for Exposures and Environmental Releases (ChemSTEER). This tool consists of peer reviewed mathematical models and industry-specific release and exposure scenarios that can be used to estimate exposures and releases in the absence of data and/or to augment available data. Note: The views expressed in this abstract are those of the author and do not represent Agency policy or endorsement

## **S02.02.37. Worker Use Description and Exposure Assessment**

Rosalie Tibaldi

*Rosalie Tibaldi<sup>1</sup>*

*1. ExxonMobil Biomedical Sciences, Annandale, NJ, United States.*

Abstract: An important component in chemical risk evaluation is to have a common understanding of how substances are used in occupational settings, including work conditions and exposure controls. Identifying every workplace activity and associated condition would result in a large set of highly specific scenarios, each of limited application. An alternative approach is to more generically group tasks when high throughput exposure estimates are desired and conservative models applied. Exposure potential for workers in these respective activities or process types can be linked to emission profiles based on substance physical chemical properties. For example, products containing a moderate volatility solvent applied by hand brush can be expected to result in like inhalation risk under like use conditions, regardless if the product is a paint, adhesive, or cleaning agent. Amended TSCA defines conditions of use as "the circumstances, as determined by the Administrator, under which a chemical substance is intended, known, or reasonably foreseen to be manufactured, processed, distributed in commerce, used, or disposed of." Similarly under REACH use and conditions of use "means any processing, formulation, consumption, storage, keeping, treatment, filling into containers, transfer from one container to another, mixing, production of an article or any other utilization". In modernized countries industrial work environments are likely to have similar operations and worker regulatory protections to prevent exposure. Therefore, exposure evaluation approaches and tools applied to assess substance uses for EU REACH may also be helpful to inform risk evaluations under amended TSCA. This presentation overviews REACH use description for worker exposure assessment and fundamental input parameters used to screen occupational exposure risks. Concepts and approach will be highlighted with an example using the ECETOC targeted risk assessment tool.

## **S02.02.38. Exposure Assessment Tools from the American Industrial Hygiene Association: A Review with Examples of Their Use**

Thomas Armstrong

*Thomas Armstrong<sup>1</sup>, Daniel Drolet<sup>2</sup>*

- 1. TWA8HR Occupational Hygiene Consulting, LLC, Branchburg, NJ, United States.*
- 2. Retired, Longueuil, QC, Canada.*

Abstract: Software tools developed in the AIHA Exposure Assessment Strategies Committee provide ways to statistically evaluate data and evaluate occupational/consumer exposure scenarios. The tools are free and are regularly updated. Several (1 to 3 below) are available in multiple languages. The following five tools will be discussed with examples of their use. IH STAT is an Excel application that calculates a variety of exposure statistics, performs goodness of fit tests, and graphs exposure data. IH MOD is a mathematical modeling Excel spreadsheet suite of 11 algorithms used for estimating air concentration exposures. A new version IH Mod 2.0 additionally provides native in MS Excel Monte Carlo Simulation. IH SkinPerm is also an Excel application for estimating the dermal uptake or evaporation of dermally deposited agents. It also provides estimates of dermal absorption from air. IH Exposure Scenario Tool (IHST) guides evaluation of the workplace, specific scenarios and agents(s), key determinants of exposure and the type of engineering controls. This information is then used with the Qualitative Exposure Assessment Checklist. Qualitative Exposure Assessment Checklist requires: An OEL; the Vapor Pressure of the pure chemical (VP) if in gas or vapor form; the identified workplace controls and the required level of workplace controls. It can be applied in a few minutes using readily available information and has been shown to be more accurate than subjective professional judgments.

## **S02.02.39. Exposure Data Quality Issues and TSCA Assessments**

Judy LaKind

*Judy S. LaKind<sup>1</sup>*

*1. LaKind Associates LLC, Catonsville, MD, United States.*

Abstract: EPA's Federal Register Notice on Procedures for Chemical Risk Evaluation under the Amended Toxic Substances Control Act includes several references to the use of quality assessments for evaluating information and inclusion of quality assessments in systematic reviews. The Notice also points to the importance of using predefined criteria for assessing quality. However, rapid technological advances are producing exposure data for which there are no available data quality assessment tools. While various fields have developed approaches to rigorously and transparently assessing data quality, there is as yet no holistic approach for assessing both measured and modeled data in the context of a fit-for-purpose assessment. Using key elements from existing approaches to assessing exposure data quality, we developed an instrument - ExpoQual - for evaluating the quality of human exposure data that is applicable to both traditional sources of exposure data (the focus here is primarily quantitative measured and modeled data) as well as newer and developing approaches and includes fit-for-purpose considerations. The key strength of ExpoQual is that it facilitates a structured, reproducible and transparent approach to exposure data quality evaluation and forces an explicit determination with regards to fit-for-purpose. The instrument is agnostic regarding whether error introduced by quality issues is systematic (biased in a particular direction) or random and the framework construct does not include data rejection. ExpoQual is designed for development into an online tool; early uses with case studies and feedback from the exposure community will result in an iterative process of instrument advancement. In this presentation we describe the ExpoQual instrument and a case study testing the efficacy of the instrument.

## O02.03A. Air Pollution and Vegetation

### **O02.03.01. Associations of PM2.5 and Out-of-Hospital Sudden Unexpected Death across Strata of Greenspace Metrics and Personal Characteristics**

Kristen Rappazzo

*Kristen Rappazzo<sup>1</sup>, Jianyong Wu<sup>1</sup>, Golsa Joodi<sup>2</sup>, Sarah Hoffman<sup>2</sup>, Irion Pursell<sup>2</sup>, J. Paul Mounsey<sup>2</sup>, Wayne Cascio<sup>1</sup>, Laura Jackson<sup>1</sup>, Ross J Simpson<sup>2</sup>*

*1. Environmental Public Health Division, U.S. Environmental Protection Agency, Research Triangle Park, NC, United States.*

*2. University of North Carolina Chapel Hill, Chapel Hill, NC, United States.*

**Abstract:** Out-of-hospital sudden unexpected deaths (OHSUD) are natural deaths that occur without obvious underlying causes and account for nearly 1 in 6 deaths in the United States. In previous work, we have observed increased odds of OHSUD with (1) increased exposure to PM2.5 in a case-crossover study, and (2) with lower levels of census tract greenway density in an ecological study. Our objective here was to examine potential effect measure modification of the PM2.5-OHSUD association by greenspace metrics and individual characteristics. OHSUD cases in Wake County, NC for March-01-2013 to February-28-2015 (n=399) from the University of North Carolina at Chapel Hill SUDDEEN project, with data on individual characteristics from medical records, were linked to PM2.5, central site from the Air Quality Data Mart, and census tract greenspace metrics, created from the National Land Cover Dataset and county government GIS data. Using a case-crossover design, conditional logistic regression was used to estimate OHSUD ORs (95% CI) for a 5µg/m<sup>3</sup> increase in PM2.5 with a 1-day lag, adjusted for same-day average temperature and relative humidity (both natural splines), across different strata of potential modifiers. Adjusted, unstratified PM2.5-OHSUD OR was 1.18 (0.98, 1.41). For individuals in census tracts with below county median greenway density, the PM2.5-OHSUD OR was 1.38 (1.06, 1.79), while for those in census tracts with above county median greenway density the OR was 1.00 (0.76, 1.31). Individuals with a BMI >30 had an OR of 1.46 (1.01, 2.11), while those with a BMI <30 had an OR of 1.10 (0.88, 1.36). While further investigation is needed due to study size limitations, these results could prove useful for strategies connecting health care practitioners or city planners with information about air quality and factors within the built-environment that foster healthy living. This abstract does not necessarily reflect EPA policy.

## **002.03.02. Associations between Ambient Fine Particulate and Systolic Blood Pressure in Relation to Greenness in the PURSE-HIS Cohort**

Kevin Lane

*Kevin J. Lane<sup>1</sup>, Ketch Cowan<sup>2</sup>, Jahnvi Sunderarajan<sup>3</sup>, Kalpana Balakrishnan<sup>3</sup>, Sadagopan Thanikachalam<sup>3</sup>, Mohan Thanikachalam<sup>4</sup>*

- 4. Tufts University School of Medicine, Boston, MA, United States.*

**Abstract:** Background Globally, high systolic blood pressure (SBP) is major cause for cardiovascular mortality. Air pollution can adversely affect SBP, while greenness has been shown to improve SBP. Here we assess the association between long-term concentrations of ambient PM<sub>2.5</sub>, SBP and greenness in the Population study of Urban, Rural, Semi-urban Endovascular disease and Holistic Intervention Study (PURSE-HIS) in Tamil Nadu, India. Methods The study included 8080 randomly selected participants (mean age 42 years; 58% women). We used PM<sub>2.5</sub> estimates developed for Global Burden of Disease, which combined satellite-based estimates, chemical transport model simulations, and ground measurements to produce global estimates of annual average PM<sub>2.5</sub> concentrations. We measured greenness using MODIS derived normalized difference vegetation index (NDVI). Brachial BP was assessed in the dominant arm and an average of 3 measurements was used in the analysis. The associations were examined using generalized linear regression models controlling for age, gender, waist circumference, physical activity, sodium intake, smoking, stress, and anxiety. Results The PM<sub>2.5</sub> exposure estimates ranged from 18 $\mu\text{g}/\text{m}^3$  to 35 $\mu\text{g}/\text{m}^3$  in the study area. In independent multivariate models an IQR increase in PM<sub>2.5</sub> (3.0  $\mu\text{g}/\text{m}^3$ ) was associated with a 5.5 mmHg (95%CI: 4.9, 6.2) change in SBP. Stratification of participants by tertiles of NDVI showed markedly higher association of PM<sub>2.5</sub> with SBP when comparing those residing in low NDVI areas (5.0 mmHg [95%CI: 3, 6.9]) to those in medium (3.7 mmHg [95%CI: 2.8, 4.6]) and high NDVI areas (1.1 mmHg [95%CI: -0.6, 2.8]). Conclusions PM<sub>2.5</sub> was associated with SBP independently, with significant modification of this association by greenness with the largest PM<sub>2.5</sub> associations in the lowest tertile of greenness. Further studies are required to assess interaction between PM<sub>2.5</sub> and greenness on other biomarkers of cardiovascular health.

### **002.03.03. The Effect of Particulate Air Pollution on Hospitalization and Effect Modification by Green Space**

Seulkee Heo

*Seulkee Heo<sup>1</sup>, Michelle Bell<sup>1</sup>*

**Abstract:** Although benefits of greenness promoting physical activities and reducing air pollution have been suggested, studies examining the modifying effect of greenness on the relationship between short-term exposure to air pollution and morbidity risk are scarce. We quantified health benefits of green space for reducing the risk of hospitalizations due to particles (PM10 and PM2.5) in urbanized U.S. counties for 2000-2013. Normalized Difference Vegetation Index (NDVI), which ranges from -1 to 1 with higher values indicating larger density of vegetation, was used as a proxy of greenness. We used time-series analyses and meta-regression to calculate overall impact of air pollution on hospitalization aged 65 years and over for various diseases across 364 counties. Meta-regression models quantified the changes in the county-specific risks of hospitalization explained by the county-level average NDVI controlling for socio-economic factors. The effect modification of NDVI by 0.1-unit change (5% of the range of index) was quantified as percent change in the number of hospital admissions associated with a 10-unit increase of fine particles. On average across the counties, all study diseases showed significant increases in the rate of hospital admissions with PM2.5 and some diseases with PM10. Range of the NDVI effect modification in the form of percent change in cause-specific hospitalizations associated with a 10  $\mu\text{g}/\text{m}^3$  increase in particles was -7.1% to 3.8% for PM10 and -0.6% to 0.1% for PM2.5. The estimates were significant for ischemic heart (-7.1%) disease and all respiratory diseases (-1.1%) associated with PM10. The results comparing sex and age showed significantly higher NDVI effect modification for reducing the risks of stroke associate with PM10 and PM2.5 for men and younger patients. Our results identified the health benefits of community-level greenness for reducing the health burdens of hospitalizations due to air pollution in the elderly population in urban areas.

#### **002.03.04. Relationships between Greenness and Low Birth Weight: Investigating the Interaction and Mediation Effects of Air Pollution**

Jun Wu

*Olivier Laurent<sup>1</sup>, Tarik Benmarhnia<sup>3</sup>, Cristina Milesi<sup>4</sup>, Jianlin Hu<sup>5</sup>, Lianfa Li<sup>1</sup>, Michael Kleeman<sup>5</sup>, Myles Cockburn<sup>2</sup>, Jun Wu<sup>1</sup>*

**Abstract:** This large population-based study investigated the relationships between low birth weight (LBW, <2,500 gram) in term born infants ( $\geq 37$  gestational weeks), residential greenness, and the potential influence of air pollution in these relationships (joint effect, mediation) using data from 2001-2008 birth certificate records in California. Residential greenness was assessed by the Normalized Difference Vegetation Index (NDVI) within circular buffers surrounding maternal homes; while complementary indicators of air pollution exposure were estimated for the major air pollutant components (i.e. PM<sub>2.5</sub>, NO<sub>2</sub> and O<sub>3</sub>). Multi-level Poisson regression was applied with random effect at the hospital level and adjusted for potential confounders. We investigated associations between greenness and LBW within different population subgroups including urban/rural areas and different socioeconomic (SES) levels. We investigated the potential effect measure modification of air pollution on both additive and multiplicative scales. We also conducted mediation analysis, using a product of coefficients method, in order to quantify the contribution of local air pollutants abatement or increase due to greenness on LBW. In total, 72,632 singleton LBW cases were included. We observed a reduction of LBW risk associated with an increase in residential NDVI. This association was only observed in urban areas and was strongest in populations with the lowest SES levels. No interaction (neither additive nor multiplicative) was observed between NDVI and air pollution on LBW risk. The mediating effect of PM<sub>2.5</sub> in the impact of greenness on LBW was 16.7%. We provided empirical evidence for reduced risk of term LBW associated with maternal residential greenness, particularly on urban areas and among low SES women. Air pollution does not appear to modify this association but we found that a pathway in which greenness benefits to LBW is through a local reduction in air pollution.

## **O02.03.05. The Relationship between Long-Term Exposure to Neighbourhood Greenness and Air Pollution and Cardiovascular Mortality in Urban Areas in Belgium**

*3. Center for Operations Research and Econometrics (CORE), Université catholique de Louvain, Louvain-la-Neuve, Belgium.*

**Abstract:** Background Few large-scale studies have evaluated the association between residential green, air pollution and cause-specific mortality. Our study investigates the relationship between long-term residential exposure to green spaces, air pollution and cardiovascular (CV) mortality in adults living in the five largest cities in Belgium. Methods We used the Belgian 2001 census linked to mortality follow-up data (2001-2011) among 18 to 65-year-old adults for the 5 largest cities in Belgium. The data contain individual information on CV mortality (ICD-10 codes I10-I70), sociodemographic variables (age, sex, education level, employment status and housing status), residential history (based on the link with the 1991 census) and annual means ( $\mu\text{g}/\text{m}^3$ ) of air pollution (PM10, PM2.5, NO2 and BC) for the residential addresses. Different measures of green (percentage (+ 600m buffer), proximity and fragmentation of green) based on land use data (CORINE land cover) were available at the scale of census tracts. Cox proportional hazards models, where age was used as the underlying time scale, were performed to probe into CV mortality. Results We studied  $\approx 2$  million adults with 10.25 years of follow-up and observed  $\approx 11,200$  CV deaths. Consistent statistically significant effects were found for the different measures of green in the adjusted models. Hazard ratio's for the % of neighbourhood green per increase in IQR and % of green within a 600m buffer were 0.969 (99% CI 0.952-0.987) and 0.866 (99% CI 0.830-0.905), respectively. Results show independent effects for the measures of green on CV mortality when adjusted for the different pollutants separately. Sensitivity analyses including only non-movers showed similar results. Conclusion Our results suggest a beneficial association between exposure to residential green and CV mortality. Further analyses will be conducted within this study to confirm our results.

## **O02.03.06. Using Mobile Technology to Understand Local Environmental Factors Associated with Symptoms of Asthma and Allergic Rhinitis**

Fay Johnston

*2. School of Natural Sciences, University of Tasmania, Hobart, TAS, Australia.*

**Abstract:** BACKGROUND: AirRater is a smartphone application that tracks symptoms, air quality, weather and pollen. We aimed to identify the most important environmental factors associated with symptoms of allergic rhinitis and asthma among app users in three geographic regions of Tasmania, Australia. METHODS: We analysed daily symptom reports relating to the eyes, nose and lungs, with measures of particulate matter (PM<sub>2.5</sub>), pollen from locally abundant taxa, temperature, humidity, and rainfall from September 2015 through July 2017. We implemented separate negative binomial regression models for each region, adjusting for time trends, seasonal cycles, and fluctuations in the number of active app users through time. RESULTS: 3,443 individuals, 84% of whom reported having either asthma or allergic rhinitis, provided 12,396 symptom reports during the study. 74.5% of these related to the nose or eyes and 26.5% to the lungs. Associations with environmental predictors were similar across the three regions. In the largest region of Hobart, total combined symptom reports increased in association with daily PM<sub>2.5</sub> (IRR 1.05 95%CI 1.03 - 1.07) per 10µg/m<sup>3</sup>, maximum temperature (IRR 1.032 95%CI 1.014 - 1.050) per degree, and relative humidity (IRR 0.93 95%CI 0.87 - 0.98) per 10% increase. Symptoms were also strongly associated with tree pollen concentrations, especially Betula (Birch) (IRR 1.08 95%CI 1.02 - 1.15), Cupressaceae (Cypress) (IRR 1.04 95%CI 1.01 - 1.07), and Dodonaea (Hop bush) (IRR 1.01 95%CI 1.00 - 1.03) per 10 grains/m<sup>3</sup>. Associations with individual symptoms of the nose, eyes and lungs were generally consistent for air quality and meteorological variables. There was greater variation between lung, eye and nose symptoms and pollen concentrations for several plant taxa. CONCLUSIONS: App-based symptom data is a promising source of information for understanding the environmental determinants of day-to-day symptoms in people with asthma and allergic rhinitis.

## O02.03B. Effects of Temperature 1

### **O02.03.07. Modeling Temperature-Related Mortality Using Nonlinear Autoregressive Models with Exogenous Input**

Cameron Lee

*Cameron C. Lee<sup>1</sup>, Scott Sheridan<sup>1</sup>*

*1. Geography, Kent State University, Kent, OH, United States.*

Abstract: Various modeling methodologies have been used to examine the time-lagged and nonlinear relationship between weather and human mortality. One emerging modeling framework in various environmental fields is an artificial neural network-based time series model known as nonlinear autoregressive models with exogenous input (NARX models). The objectives of this research were to demonstrate the utility of NARX models to the environmental epidemiology research community via an investigation of temperature-related mortality. Comparisons with the commonly-used distributed lag nonlinear model (DLNM) are also presented. Minimum and maximum daily apparent temperatures and daily all-cause mortality data were collected for 41 different US cities, 1979-2010. NARX models were trained to predict daily mortality from 60% of the data in each city, while 20% of data was held out for both internal validation and independent external testing. Model performance varied by location and season, with the highest performance generally coming in populous cities and the winter season. Across the US as a whole, median absolute percentage errors were 10.2% and the models improved the explained variance over that of a simple persistence model by 18 percentage points. Top quintile spike days in mortality were also skillfully predicted 54% of the time, with some locations correctly modeling over 70% of these spikes. NARX comparisons with DLNMs revealed nearly identical time-lagged relationships, largely in agreement with previously published research. These results exhibit the ability of NARX models in predicting complex, time-dependent relationships that could be useful for diverse applications in epidemiological research.

## **002.03.08. Multiple Determinants of Vulnerability for Emergency Department Visits for Heat-Related Illness in California 2005-2008 Warm Seasons**

Helene Margolis

*Helene G. Margolis<sup>1</sup>, Machel D. Wilson<sup>2</sup>, Jennifer Kwan<sup>5</sup>, Eric M. Roberts<sup>3</sup>, Michelle Wong<sup>3</sup>, Alexander Gershunov<sup>4</sup>, Kristen Giurguis<sup>4</sup>, Paul B. English<sup>3</sup>*

- 3. Public Health Institute, Oakland, CA, United States.*
- 4. Scripps Institution of Oceanography, UCSD, La Jolla, CA, United States.*
- 5. University of California, Davis, Sacramento, CA, United States.*

**Abstract:** Background: High temperatures are associated with risk of Heat-Related Illness (HRI) and other acute clinical outcomes. Information on HRI risk factors is rarely place-based; decision-makers need local-scale (e.g., neighborhood) data to inform strategies to reduce heat health impacts. Objective: In multi-determinant multi-level models assess relations between daily maximum temperature (Tmax) and emergency department (ED) visits for HRI and vulnerability factors, i.e., biological susceptibility (e.g., sex, age, race), physical environment (e.g., land-use, air quality), or socioeconomic (e.g., neighborhood assets). Methods: CA Office of Statewide Healthcare Planning and Development ED data for 2005-2008, restricted to the warm seasons (May 1-October 31) were used. Cases were defined as a HRI diagnosis (International Classification of Diseases (ICD) ninth revision, clinical modification (ICD9-CM) code 992.0-992.9). Non-HRI cases were retained as controls. Exclusions: If date of visit or residence ZIP code (ZC) was missing. ZC were converted to Zip Code Tabulation Area (ZCTA) to link census tract data to patients. Hierarchical generalized linear models with a logit link (SAS v9.3 PROC GLIMMIX) were used. For each exposure (daily Tmax, daily O3 or PM10) models included both the ZCTA-specific 4-year seasonal mean (Tmaxmn), and ZCTA-day (i.e., ED visit date) deviation from that mean (Tmaxdif). Interaction terms were used to evaluate effect modification. Results: HRI risk was positively associated with Tmaxdif (OR 1.02 95%CI: 1.016, 1.019, p<.0001), and co-exposure to O3 (Tmaxdif\*O3dif) increased the risk (OR 1.051 95%CI: 1.043, 1.059, p<.0001). Risk varied by age group, sex and race/ethnicity, with girls (especially those ≤ 10 years), African American and Hispanic children, and elderly Black at greatest risk. ZCTA %-impervious surfaces, % multi-family homes were positively associated with HRI. These and other results pointed to interventions to reduce HRI risk.

## **O02.03.09. The Relationship between Extreme Heat and Cardiovascular Mortality: Assessing Effect Modification by Social Vulnerability Metrics**

Ambarish Vaidyanathan

*Ambarish Vaidyanathan<sup>1</sup>, Ana M. Vicedo-Cabrera<sup>2</sup>, Nabil Abdurehman<sup>3</sup>, Francesco Sera<sup>2</sup>, Antonio Gasparrini<sup>2</sup>*

*3. ORISE-CDC, Atlanta, GA, United States.*

Abstract: Heat-Mortality relationships show heterogeneity across populations; however, extant literature sheds little light on the factors, especially social determinants of health, responsible for this differential heterogeneity. Our objective was to assess the effect modification by social vulnerability metrics (SVMs) on the association between heat and mortality. A two-stage time-series analysis with distributed lag non-linear models was used to model the exposure-response (E-R) relationships between heat and mortality in 2,431 counties in the United States for years, 2001-2012. The risk estimates were pooled in a meta-regression framework to examine how SVMs modified the E-R relationships. A counterfactual health burden analysis was applied to quantify the extent of the effect modification by estimating fractions of deaths attributed to heat (AF) at various percentiles of each SVM. The SVMs used in this assessment ranged from commonly used sociodemographic variables to a composite community-specific Heat-Related Social Vulnerability Rating (HRSVR). The HRSVR and several SVMs, including socioeconomic status (e.g., % with no high school diploma), housing (e.g., % of households with no vehicles), and minority status (e.g., % of population with limited English speaking abilities) variables were significantly associated with an increase in heat-attributed mortality. Across all climate regions, the increase in AF of deaths for an interquartile increase in HRSVR levels was 0.59% (95%CI: 0.55%-0.63%). Health burden is likely to increase with increasing social vulnerability levels and the extent of effect modification varies with SVMs. The results from this assessment could potentially be used to identify at-risk areas based on their levels of social vulnerability and design community-specific heat intervention plans to help prepare for extreme heat emergencies.

## **O02.03.10. Nonparametric Bayesian Multivariate Meta-Regression with Functional Meta-Predictor: An Application in the Temperature-Mortality Study**

Yeonseung Chung

*Jaeun Yoo<sup>1</sup>, Masahiro Hashizume<sup>2</sup>, Yoonhee Kim<sup>3</sup>, Yasushi Honda<sup>4</sup>, Chris F. Ng<sup>2</sup>, Yeonseung Chung<sup>1</sup>*

*1. Department of Mathematical Sciences, Korea Advanced Institute of Science and Technology, Daejeon, Korea (the Republic of).*

*2. Institute of Tropical Medicine, Nagasaki University, Nagasaki, Nagasaki, Japan.*

*3. Department of Global Environment and Public Health, Tokyo University, Tokyo, Japan.*

*4. Faculty of Health and Sport Sciences, Tskuba University, Tskuba, Japan.*

**Abstract:** Background/Aim: Time-varying temperature-mortality association has been reported in numerous research, but little is known about the time-varying predictors that may underlie the changing association. Multivariate meta-regression has been used in the temperature-mortality study to combine evidences from multiple locations with meta-predictors incorporated. However, the current form of meta-regression is limited as it does not incorporate time-varying meta-predictors. Methods: We introduce a nonparametric Bayesian multivariate meta-regression incorporating functional meta-predictors to estimate the temperature-mortality association changing over time and identify the time-varying predictors related with the temporal changes. Our modeling framework is a two-stage approach; the first stage uses the time-varying distributed lag nonlinear model to estimate the time-varying association for each location, and the second stage pools the location-specific time-varying associations incorporating time-varying meta-predictors. For the second stage, we formulate a nonparametric (np) Bayesian multivariate meta-regression, which identifies clusters based on both the time-varying associations and the overtime trajectory of meta-predictors. Our method was applied to the daily time series data of temperature and mortality collected for 47 prefectures in Japan for 1972-2012. The prefecture-specific yearly air conditioning (AC) prevalence was used as a time-varying meta-predictor. Results: Results indicated that there are two major clusters; cluster 1 showed the clearly decreasing heat-related mortality over time with a sharply increasing AC curve, cluster 2 showed the slowly decreasing heat-related mortality over time with a gradually increasing AC trajectory. Conclusions: Our proposed method is a promising statistical approach for exploring the influence of functional meta-predictors on an exposure-response association characterized complexly by multiple parameters in meta-analysis.

### **O02.03.11. Comparison of Temperature-Mortality Associations Estimated with Point-Based Temperature Observations Versus Spatially-Resolved Temperature Estimates**

Kate Weinberger

*Kate R. Weinberger<sup>1</sup>, Keith Spangler<sup>1</sup>, Antonella Zanobetti<sup>2</sup>, Joel D. Schwartz<sup>2</sup>, Gregory A. Wellenius<sup>1</sup>*

*1. Epidemiology, Brown University School of Public Health, Providence, RI, United States.*

*2. Environmental Health, Harvard T.H. Chan School of Public Health, Boston, MA, United States.*

**Abstract:** Background: Studies of the association between ambient temperature and mortality typically rely on temperature observations from a single weather station to estimate the exposure of people living across large areas. Spatially-resolved temperature estimates may reduce exposure measurement error in locations where available weather stations are sparse or do not fully capture the exposure of the population of interest. Objective: To quantify the association between daily mean temperature and mortality in 20 large United States (US) cities, using (1) temperature observations from the airport weather station closest to each city, and (2) population-weighted temperature estimates constructed from PRISM, a high-resolution, gridded meteorological dataset. Methods: For each temperature data source and in each city, we used distributed lag non-linear time series models to estimate the 21-day cumulative association between daily mean temperature and all-ages mortality counts, controlling for seasonal and long-term trends, day of week, and federal holidays. We additionally calculated the fraction of deaths attributable to hot and cold temperatures. Results: Associations estimated using the two temperature data sources were similar in most cities. For example, in New York City, the rate ratio comparing the 99th percentile of temperature to the minimum mortality temperature was 1.25 (95% CI: 1.18, 1.32) for observed temperature and 1.27 (95% CI: 1.20, 1.34) for estimated temperature. A limited number of cities showed disparate results. Across all 20 cities, we estimate that 0.5% (95% eCI: 0.3, 0.7) and 0.6% (95% eCI: 0.4, 0.7) of deaths were attributable to heat when using observed and estimated temperature, respectively. Conclusions: On average across 20 US cities, observed and estimated temperatures yielded similar relative and absolute measures of mortality risk. Gridded datasets may be particularly advantageous in the context of populations without reliable weather observations.

### **O02.03.12. Is Temperature Linked to Mortality and Hospitalizations in Africa Settings?**

Margarita Triguero-Mas

*Margarita Triguero-Mas<sup>1</sup>, Charfudin Saccor<sup>2</sup>, Alberto Chauque<sup>2</sup>, Aura Hunguana<sup>2</sup>, Teodimiro Matsena<sup>2</sup>, Llorenç Quintó<sup>1</sup>, Erica Martinez<sup>1</sup>, Azucena Bardaji<sup>1</sup>, Clara Menendez<sup>1</sup>, Xavier Basagaña<sup>1</sup>*

- 1. ISGlobal, Barcelona, Spain.*
- 2. CISM, Manhica, Mozambique.*

**Abstract:** Although many studies have indicated that extreme temperatures may increase mortality, there is paucity of information on hospitalizations and climate-health relationships in Africa. To address these shortfalls, we assessed the association between temperature and mortality and hospitalizations in Mozambique. We also investigated whether these relationships differed by population and diagnose subgroup. We used data from a cohort study established at the District of Manhica (Mozambique). We obtained sociodemographic and mortality data from all the population and hospitalizations data from those 15 years old or younger for the period 1996-2017. Data on temperature were derived from NASA's Modern-Era Retrospective Analysis for Research and Applications (MERRA) model. We fitted quasi-Poisson time series regression models for each health outcome with temperature as an independent variable. There was a mean incidence of 3 deaths and 3 hospitalizations daily. Coinciding with a big flood, higher incidences occurred on 2000 and 2001. Decreases on mortality and hospitalizations from 2014 onwards concurred with health services improvements in the area. There was a significant association between mortality and hospitalizations and the climatic variables in Manhica. Accumulating all the three evaluated lags, for extreme cold (i.e. 2.5th percentile) the mortality relative risk, RR, was 1.07 (95% CI:1.01, 1.13), while for extreme heat (i.e. 97.5th percentile) it was 1.25 (95% CI: 1.08, 1.44). In the case of hospitalizations, for extreme cold RR was 1.96 (95% CI: 0.89, 4.34) and for extreme heat it was 2.12 (95% CI: 0.95, 4.75). Our analyses by subgroups only showed small differences on the mortality by age group. Most of the temperature-related health outcomes were attributable to contributions of heat. This evidence has important implications for the planning of public-health interventions, especially when taking into account future effects of climate change.

## 002.03C. Exposure and Health Effects Related to Waste

### **002.03.13. Relationship between Blood Lead Levels and Dietary Essential Mineral Intake in Electronic Waste Workers and a Control, in Ghana**

Sylvia Takyi

*Sylvia A. Takyi<sup>1</sup>, Julius Fobil<sup>1</sup>, John Arko-Mensah<sup>1</sup>, Nil Basu<sup>4</sup>, Thomas Robins<sup>3</sup>, Afua A. Amoabeng<sup>1</sup>, Karel G. Houessionon<sup>2</sup>, Augustine Acquah<sup>1</sup>, Lawrencina Kwarteng<sup>1</sup>*

**Abstract:** Background: Several toxic metals are known to interact with, and affect absorption of micro nutrients in the gastro-intestinal tract. Although studies have reported high levels of lead (Pb) in electronic waste (e-waste) workers, the possible interaction and impact on availability of essential minerals in the body have not been extensively studied. Objectives: The aim of this study was to investigate the relation between blood lead levels (BLL) and dietary essential mineral (Ca, Fe, Mg, Zn, Cu) intakes of e-waste workers and a control group. Methods: This prospective cohort study, which is part of the ongoing West Africa GEOHealth II project, compared 100 e-waste workers at Agbogbloshie (exposed) to 50 controls (unexposed). 10 ml of whole blood was collected and analyzed for Pb using the Inductively Coupled Plasma Mass Spectrometry (ICP-MS). Essential mineral intakes were assessed using a 2 day 24 hour recall and analyzed by the Esha F-Pro nutrition software. Statistical analysis was done using SPSS (Version 22). BLL and essential minerals were reported using means, standard deviations (SD) and ranges. Results: Overall, mean (SD) BLL was higher ( $9.24 \pm 6.37 \mu\text{g/dL}$ ) in e-waste workers, range (2.42-41.60  $\mu\text{g/dL}$ ) than the control group ( $4.10 \pm 1.92 \mu\text{g/dL}$ ), range (1.51-14.04  $\mu\text{g/dL}$ ). BLL levels were mostly above 10  $\mu\text{g/dL}$  at e-waste site (28%), compared to control site (2%). Mean intakes of Ca, Zn, Cu and Mg in the diet were low in both groups, but Fe was adequate. A simple linear regression model showed a positive relationship between BLL and Ca intake ( $r = 0.39$ ,  $p < 0.001$ ). Conclusions: Diet taken lacked adequate levels of Zn, Cu and Mg among all study participants. There was a positive relationship between Ca levels and BLL. This preliminary data suggests the need to supplement existing dietary intake with certain micronutrients. Key Words: Essential minerals, Lead, Whole Blood, E-waste, Ghana

## **002.03.14. Mercury Exposure: Impact on Birth Outcomes in Suriname**

Renske Wouters

**Abstract:** Background Small-scale gold-mining operations in Suriname use mercury (Hg) for gold extraction. Exposure during pregnancy can negatively influence birth outcomes and neurodevelopment. The Caribbean Consortium for Research in Environmental and Occupational Health is assessing exposure to metals in 1000 mother/child dyads. This study evaluates the association between Hg exposure in pregnant women and birth outcomes. Methods Hair samples were analysed for total Hg and associated with birth outcomes collected from parturition books and clinical records. Adverse birth outcomes included stillbirths, congenital anomalies, low APGAR score at 5 minutes (<7), low birth weight (<2500g), and preterm birth (<37 weeks). Logistic regression analysis was used to determine the association between hair Hg levels (high Hg was defined as exceeding the 1.1 µg/g USEPA action level) and adverse birth outcomes. Results Preliminary data showed a median [Hg] in hair of 246 women was 0.64 µg/g (range < LOD-6.86 µg/g; IQR 0.39-1.07), 60 women (24.4%) exceeded 1.1 µg/g. In multivariable logistic regression analysis women with lower secondary education or less had a high [Hg] compared to women with higher secondary education and up (OR 2.84; 95%CI 1.50-5.39; p=0.001). Women of Asian descent had an [Hg] comparable to those of African descent (p=0.096). Overall 24.1% of women had adverse birth outcomes, 28.3% in women with high [Hg] vs. 25.3% with low [Hg] (p=0.638). Conclusion One out of 4 pregnant women in Suriname had hair Hg concentrations that exceeded the USEPA action level. Adverse birth outcomes were not influenced by high Hg levels. Remarkably, lower educated women showed high Hg levels, warranting further investigation. This dataset was mainly limited to women from Suriname's coastal area. Including more women from the interior, who are expected to be more severely exposed, may alter the effect of Hg on birth outcomes. Funding FIC/NIH U01TW010087-01, U2RTW010104

## **002.03.15. Occupational Exposure to Flame Retardants among Canadian E-Waste Dismantlers**

Victoria Arrandale

**Abstract:** Background: The mass of e-waste produced globally is growing dramatically. Workers dismantling and recycling e-waste are exposed to many hazards, including flame retardants (FRs), that are added to electronics to meet flammability standards. Environmental exposure to FRs is ubiquitous and has been associated with adverse health effects including endocrine disruption (thyroid hormone dysregulation), neurological impairments and reproductive effects. This study reports on occupational FR exposure in an Ontario, Canada e-waste dismantling facility. Methods: Sampling was conducted daily over a total of five days in February 2017 in Ontario, Canada. Twenty active air samples were collected at 4 workbenches. Ten active air samples were collected over 24 hours at a central workplace location. Seven floor and 8 workbench dust samples were also collected. Samples were analysed for novel brominated flame retardants (NFRs), polybrominated diphenyl ethers (PBDEs) and organophosphate esters (OPEs), using gas chromatography mass spectrometry (GC-MS). Results: The most abundant FRs in air were the now-banned PBDEs, dominated by BDE-209 with an average concentration at the workbenches of 175 versus 108 ng/ m<sup>3</sup> at the central location ( $p < 0.05$ ). Air levels of BDE-209 were almost 5 times higher than in an earlier study in Sweden (Sjodin et al, 2001). The next most abundant compounds were TDCPP and TCCP, two OPEs. Levels of FRs in air and dust did not differ between floor and workbench. In dust, BDE-209 was the most abundant compound, followed by TPHP and TDCPP. Conclusions: Levels of FRs in air and dust collected from this Canadian e-waste recycling facility indicate that e-waste dismantlers in Ontario, Canada have inhalation exposure to FRs. Skin exposure and ingestion through hand-mouth contact are also potential routes of exposure. Though there is evidence of FR toxicity, there are no occupational limits in Canada which is a significant gap given the potential for elevated exposure.

## **002.03.16. Environmental Exposures and Asthma in Women Living in Rural Costa Rica: Results from the ISA Study**

Brooke Alhanti

**Abstract:** Background: Environmental exposures are contributors to respiratory disease around the world. Pesticide and waste burning exposure may contribute to adverse respiratory outcomes in rural areas. To evaluate the impact of environmental exposures on respiratory health, we studied women in the Infants' Environmental Health Study (ISA), a prospective cohort study of women and children living in the banana-growing region of Costa Rica. Methods: We collected information from women on respiratory outcomes (asthma symptoms and diagnosis) using the European Community Respiratory Health Study questionnaire, height, weight, and environmental exposures, and obtained a urine sample for pesticide analysis. Urine samples were analyzed for the pesticide metabolites 3,5,6-trichloropyridinol (TCP) for chlorpyrifos; dimethylcyclopropane carboxylic acid (DCCA) and 3-phenoxybenzoic acid (3-PBA) for pyrethroids; and 5-hydroxythiabendazole (OHT) for thiabendazole. For each analyte, we dichotomized the exposure measurement at the 75th percentile. We used questionnaire data to calculate an asthma score, which helps to identify untreated, symptomatic asthma. We performed a cross-sectional analysis, using logistic regression adjusted for BMI to identify environmental exposures related to asthma score and asthma diagnosis. Results: Among the 273 women, 21% reported doctor diagnosis of asthma and 39% had an asthma score consistent with asthmatic symptoms. Self-reported doctor-diagnosed asthma was associated with 3-PBA (OR=1.64, 95% CI: [0.85, 3.09]), whereas asthma score was associated with OHT (OR=1.63, [0.93, 2.85]). Asthma score was also associated with residential exposure to air pollution due to burning (OR=2.03, [1.01, 4.32]). This association was stronger with more frequent exposure to waste burning - daily exposure was more likely to lead to a high asthma score than rare exposure (OR=2.31, [1.03, 5.28]). Conclusion: Environmental exposures may contribute to respiratory symptoms in women.

## **002.03.17. Birth Outcomes Associated with Maternal and Fetal Exposure to Metals from Informal Electronic Waste Recycling in Guiyu, China**

Abstract: Informal electronic waste (e-waste) recycling is a rapidly growing industry in developing countries, as ~50 million metric tons of e-waste are generated annually. Informal e-waste recycling creates widespread environmental contamination of a mixture of chemicals. The E-waste Recycling Exposure and Community Health (e-REACH) study enrolled pregnant women in Guiyu, an informal e-waste recycling site (n=314), and Haojiang, an unexposed control site, (n=320) at delivery. We analyzed maternal blood, cord blood, and maternal urine for lead (Pb), cadmium (Cd), chromium (Cr), and manganese (Mn). We also captured data in newborns on birth weight, birth length, head circumference, body mass index (BMI), and Ponderal Index (PI). We calculated the geometric mean (GM) for each metal and calculated the ratio between sites using generalized linear models. We ran linear regression models to compare the birth outcomes between sites after adjusting for maternal age, education, occupation, BMI, gravidity, exposure to environmental tobacco smoke, and newborn sex. Maternal blood Pb, Cd, and Cr were higher in Guiyu compared to Haojiang, with a GM of Pb at 6.66 µg/dL (range: 1.87 - 27.09 µg/dL) and was 1.74-fold greater than in Haojiang (95% CI: 1.60, 1.89). Pb in cord blood was 1.53-fold higher in Guiyu (95% CI: 1.38, 1.68). Urinary Cd (2.15, 95% CI: 1.72, 2.69), Cr (1.63, 95% CI: 1.09, 2.45), and Mn (2.04, 95% CI: 2.04, 3.31) were also significantly higher in Guiyu compared to Haojiang. Guiyu neonates had significantly smaller head circumference ( $\beta$ : -1.58 cm, 95% CI: -2.03, -1.13), BMI ( $\beta$ : -0.75, 95% CI: -1.11, -0.38), and PI ( $\beta$ : -1.91 kg/m<sup>3</sup>, 95% CI: -2.98, -0.84). Birth weights were also lower in Guiyu ( $\beta$ : -41.98 g, 95% CI: -135.96, 51.9). We observed differences in the head size and Ponderal Index of neonates from Guiyu when compared to neonates from Haojiang. Since e-waste exposure is a complex mixture, the outcomes could be related to additional chemicals and interactions.

## **002.03.18. Ethical Aspects in the Assessment of Exposure and Health Effects Related to Waste**

Martin Tondel

*Martin Tondel<sup>1</sup>*

*1. Occupational and Environmental Medicine, Department of Medical Sciences, Uppsala University, Uppsala, Sweden.*

Abstract: Papers on site contamination, air monitoring and biomonitoring related to waste are presented. Exposure includes lead (Pb) soil contamination, flame retardants (FR) and metals in electronic waste dismantlers, mercury (Hg) from gold mining, and pesticide metabolites in people. Outcomes are various birth outcomes and asthma. Accuracy in measuring exposure and outcome is essential for a correct interpretation of results. Exposure assessment in non-biota (here Pb in soil, FR in air and dust) might meet a methodological and ethical challenge in evaluating accuracy and interpretation in relation to health when communicated to the exposed people. Biomonitoring needs informed consent, interpretation of results, and a communication plan. Biomonitoring of substances not having well-established toxicological effects at low levels (here FR), meets certain challenges in interpretation of data, bearing in mind statistical power, uncontrolled confounding and limitations using a cross-sectional design. Biomonitoring of substances prevalent both in occupational and environmental settings sets an ethical challenge when communicated to employers and policy makers. Studies of birth outcomes include exposure to fetuses. Protecting the most vulnerable, including the fetus, not able to advocate for themselves, is a first-order principle of biomedical ethics. Another first-order principle of bioethics is that research should avoid harm to the individuals and to the communities studied. Is there a risk of unintentional harm to the population if a study is statistically under-powered and, hence communicated as safe? What ethical considerations are needed when communicating results from occupational exposures when there are no occupational limits? Risk communication and management plans are needed to fulfill the obligation of transparency to the study population. These questions will be addressed in the ethics discussion.

O02.03D. Exposure Assessment, Susceptibility, and Demographic Factors in Studies of Air Pollution Mediated Mortality

**O02.03.19. Refined Estimates of PM2.5 Exposure and Associated Mortality Burden Using Mobile Phone Big Data**

Jiongchao Ding

*Jiongchao Ding<sup>2</sup>, Daniel Bi<sup>2</sup>, Qi Zhou<sup>1</sup>, Zheng Zhu<sup>2</sup>, Miaomiao Liu<sup>1</sup>*

*1. School of the Environment, Nanjing University, Nanjing, Jiangsu, China.*

*2. Nanjing Foreign Language School, Nanjing, China.*

**Abstract:** Introduction: The improvement of transportation infrastructure, especially the development of high-speed trains, has greatly stimulated the increase of population mobility. Based on census data, existing studies have attempted to quantify the long-term trends of population migration and the consequent environmental impacts. This, however, captured only a small part of population mobility. It ignored the short-term mobility across scales of weeks, days, or even hours, and consequently introduced significant biases in assessing PM2.5 exposure and associated mortality burdens. Methods: In this context, the geographically and time-referenced Call Detail Records (CDRs) makes it possible to address the issues we mentioned above. So in this study, we extracted hourly spatialized population density maps in Jiangsu Province from the CDRs of about 40 million mobile phone users in over 310 thousand macro cells. Based on this Dynamic Population Distribution (DPD), as well as spatiotemporal PM2.5 concentration levels and localized PM2.5 doses-response relationship, we used the Relative Risk Model to evaluate the population-weighted PM2.5 attributed deaths. Finally, Mann-Whitney U Tests were carried out to assess the statistical difference of PM2.5 exposures between DPD and Static Population Distribution (SPD), between daytime and nighttime, and between workdays and weekends. Results and Discussion: The results show that significant difference ( $p < 0.05$ ) existed between DPD and SPD. In investigating the temporal variation of population-weighted PM2.5 attributed deaths under DPD, significant difference ( $p < 0.05$ ) between daytime and nighttime can also be found in most of the areas in Jiangsu Province. The difference shows that when more detailed information is included, results from the traditional method may be challenged. The introduction of CDRs data can help us minimize the uncertainties and provide better information for the development of mitigation and adaption strategies.

## **O02.03.20. A Marginal Estimate of PM2.5 Effects on Mortality Using Propensity Scores and Exposure Randomization by Moving**

Yara Abu Awad

*Yara Abu Awad<sup>1</sup>, Qian Di<sup>1</sup>, Yan Wang<sup>1</sup>, Christine Choirat<sup>1</sup>, Brent A. Coull<sup>1</sup>, Francesca Dominici<sup>1</sup>, Antonella Zanobetti<sup>1</sup>, Joel D. Schwartz<sup>1</sup>*

*1. Environmental Health, Harvard T.H. Chan School of Public Health, Brighton, MA, United States.*

**Abstract:** Introduction: Multiple observational studies have found an association between ambient PM2.5 and mortality, and while they all adjusted for confounding, inferring causality is always challenging. In this study, we leverage information on changing residential address (moving) to design an observational study that will be less sensitive to confounding bias. Methods: In the Medicare cohort aged 65 and older, we identified about 10 million movers and 52 million non-movers and then used a previously validated exposure prediction model to assign mean annual PM2.5 exposure. We checked if moving randomized subsequent exposure by comparing the standardized differences in confounders by exposure in movers to non-movers. We controlled for potential individual and ecological confounders and Zip code of origin using propensity score models to generate inverse probability weights (IPWs) among white and black movers separately and applied these weights in Cox proportional hazards models to estimate the risk of all-cause mortality. Results: All standardized differences were smaller among white movers compared to non-movers indicating randomization to exposure. Among black movers, all standardized differences were smaller except for Medicaid eligibility and % home ownership at the Zip code level (these differences were slight). Using our IPWs, per 10  $\mu\text{g}/\text{m}^3$  of PM2.5 exposure we found a hazard ratio of 1.15 (95% CI: 1.14 to 1.16) among whites and 1.23 (1.21-1.26) among blacks. Hazard ratios held even when restricting these analyses to movers exposed to levels below the current US EPA standard of 12  $\mu\text{g}/\text{m}^3$ . Conclusion: We used a pseudo-randomization approach (moving) to obtain protection against unmeasured confounders combined with a propensity score approach, which makes exposure independent of measured covariates, and found a highly significant effect of PM2.5 on death rates, which is likely causal and continues below current standards.

### **O02.03.21. The Concentration-Response between Long-Term PM2.5 Exposure and Mortality: A Meta-Regression Approach**

Alina Vodonos Zilberg

*Alina Vodonos Zilberg<sup>1</sup>, Yara Abu Awad<sup>1</sup>, Joel D. Schwartz<sup>1</sup>*

*1. Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, MA, United States.*

Abstract: Long-term exposure to ambient fine particulate matter ( $\leq 2.5 \mu\text{g}/\text{m}^3$  in aerodynamic diameter; PM2.5) is significantly associated with increased risk of premature mortality. We provide an updated meta-analysis of all-cause and cause specific mortality associated with exposure to PM2.5 as a function of air pollution levels. We systematically searched all published cohort studies examining the association between long-term exposure to PM2.5 and mortality. We applied multivariate linear random effects meta-analysis with nested structure for cohort and study as random effects. Meta-regression techniques applied to test whether study population or analytic characteristics modify the PM2.5 -mortality association and to estimate the shape of the concentration-response curve. A total of 53 studies (39 from North America, 8 from Europe, and 6 from Asia) that provided 135 estimates of the association between the risk of mortality and exposure to PM2.5 were included in the meta-analysis. Since 2015, 17 new studies have been published, covering geographic areas with a wider range of mean exposures (e.g.  $<12$  or  $> 20 \mu\text{g}/\text{m}^3$ ). A penalized spline showed the slope decreased at higher concentrations but appeared to level off. We found that the inverse transform of average PM2.5 well approximated that spline and provided a parametric estimate that fit better than a linear or logarithmic term for average PM2.5. In addition, we found that exposure assessments using space time models or fixed monitors at Zip-code scale, or additionally controlling for area level socio-economic status were associated with higher effect estimates. This meta-analysis provides a strong evidence for the adverse effect of PM2.5 on mortality, that studies with poorer exposure have lower effect size estimates, and that more control for SES increases effect size estimates. The concentration -response function produced here can be further applied in the global health risk assessment of air particulate matter.

## **O02.03.22. Long-Term Exposure to Air Pollution and Mortality among People with and without Diabetes and Asthma or COPD**

Nicole Janssen

*Nicole A. Janssen<sup>1</sup>, Marten Marra<sup>1</sup>, Caroline Ameling<sup>1</sup>, Joost Wesseling<sup>1</sup>, Paul Fischer<sup>1</sup>, Danny Houthuijs<sup>1</sup>*

*1. RIVM, Bilthoven, Netherlands.*

**Abstract:** Introduction the association between long-term exposure to air pollution and increased risk of mortality has been well documented. However, less is known about the populations most susceptible to these effects. We evaluated the associations between long-term exposure to air pollution (PM<sub>2.5</sub>, NO<sub>2</sub> and EC) for people with and without diabetes and asthma or COPD. **Methods** We linked modelled annual average concentrations of PM<sub>2.5</sub>, NO<sub>2</sub> and EC of the year 2008 to a registration based cohort of 7.5 million Dutch residents 30 years or older, with follow-up for five years (2008-2012). We used data on individual medication prescriptions in the two years before baseline (2006+2007) to define subpopulations with and without diabetes, and with and without asthma or COPD. We used cox proportional hazard models to estimate Hazard Ratios (HR), adjusting for individual and area-level confounders. We stratified by disease status to compare risks for the different subpopulations. **Results** We identified 527 thousand cohort members with asthma or COPD and 429 thousand with diabetes. Air pollution was significantly associated with all-cause mortality for all subgroups. For the full cohort, HRs [95% confidence interval] were 1,06 [1,04-1,07] per 5 µg/m<sup>3</sup> increase in PM<sub>2.5</sub>; 1,05 [1,04-1,06] per 20 µg/m<sup>3</sup> increase in NO<sub>2</sub>; and 1,04 [1,03-1,05] per 1 µg/m<sup>3</sup> increase in EC. Hazard Rates for all-cause mortality were about 2 times higher for people with asthma/COPD compared to the corresponding reference group (e.g. HR PM<sub>2.5</sub>: 1,10 [1,07-1,13] versus 1,04 [1,02-1,06]). Differences in HRs for respiratory mortality were even more pronounced: e.g. HR PM<sub>2.5</sub>: 1,23 [1,16-1,30] versus 1,05 [0,99-1,12]). HRs for people with and without diabetes were more similar to each other. Air pollution was not significantly associated with cardiovascular mortality in any of the subgroups. **Conclusions** We found substantial higher risks for air pollution related mortality for people with asthma or COPD.

## **O02.03.23. Effect Modification of the Association of Long-Term PM2.5 Exposure and Cause-Specific Mortality: An Analysis of 64 Million U.S. Medicare Beneficiaries**

Bingyu Wang

*Bingyu Wang<sup>1</sup>, Ki-Do Eum<sup>2</sup>, Justin Manjourides<sup>3</sup>, Fatemeh Kazemiparkouhi<sup>2</sup>, Helen Suh<sup>2</sup>, Virgil Pavlu<sup>1</sup>*

*1. College of Computer and Information Science, Northeastern University, Boston, MA, United States.*

*2. Department of Civil and Environmental Engineering, School of Engineering, Tufts University, Medford, MA, United States.*

*3. Department of Health Sciences, Northeastern University, Boston, MA, United States.*

**Abstract:** Introduction. Long-term exposure to fine particulate matter (PM2.5) has been consistently associated with mortality; however, our understanding of how these associations are modified by certain characteristics, such as urbanicity and race, is more limited. Methods. We considered demographic and mortality data for over 64 million Medicare enrollees across all 40 thousand ZIP codes in the conterminous United States from 2000 to 2008. We linked these data to ZIP code and month-specific PM2.5 exposures estimated using GIS-based spatio-temporal models and fit the data using Cox proportional hazard model that were modified using data aggregation and limited-memory BFGS optimization. This modification allowed our Cox PH model to analyze data simultaneously for all 64 million Medicare beneficiaries within 10 minutes (Intel Xeon E5-2680, 56 cores). We used these models to estimate the association of PM2.5 on all cause, cardiovascular (CVD), respiratory disease and cancers (including specifics: ischemic heart disease, cerebrovascular disease, congestive heart failure, COPD, pneumonia, upper respiratory infection (URI), lung cancer), with strata for age, race, gender, and ZIP code of residence. We examined effect modification by age, race, gender, land use, and region and assessed the linearity of the dose-response relationship for each cause and by modifier. Results. We found significant positive associations of PM2.5 and all causes of death, except URI, with mortality risk ratios (RR) for non-accidental, CVD, respiratory, and cancer mortality equaling 1.244 (95% CI: 1.238, 1.251), 1.683 (95% CI: 1.669, 1.696), 1.241 (95% CI: 1.223, 1.260) and 1.160 (95% CI: 1.147, 1.172) per 10 ug/m<sup>3</sup> increase in PM2.5, respectively. We showed risk of death to be higher for beneficiaries living in urban as compared to non-urban areas, for men as compared to women, for younger ages, and individuals living in the northeastern US. PM2.5 associated RRs were similar for whites and non-whites.

## **O02.03.24. Long-Term Effect of Air Pollution on Mortality in England and Wales 2001-2006: A Change on Change Analysis**

Paul Wilkinson

*Ai Milojevic<sup>1</sup>, Ben Armstrong<sup>1</sup>, Pedram Lalla<sup>1</sup>, Ian MacKenzie<sup>2</sup>, Ruth Doherty<sup>2</sup>, Paul Wilkinson<sup>1</sup>*

*1. Public Health, Environments and Society, London School of Hygiene & Tropical Medicine, London, United Kingdom.*

*2. School of GeoSciences, University of Edinburgh, Edinburgh, United Kingdom.*

**Abstract:** Background/Aim: Long-term exposure to air pollution, particularly fine particles is known to be associated with mortality, suggesting the recent improvement in air quality in the UK might have resulted in positive impacts on mortality. We investigated the association between changes in pollution exposure and changes in mortality by small areal units (Lower level Super Output Areas - LSOAs) with a self-matched design (change on change analysis). Methods: Hour-by-hour concentrations of PM<sub>2.5</sub> (and components), PM<sub>10</sub> and O<sub>3</sub>, 2001-2006 were modelled at 5 km grid resolution using the regional atmospheric chemistry transport model, EMEP-WRF and linked to annual cause-specific mortality, and annual average at LSOA level (n=34,366). Conditional Poisson regression models were applied to estimate the association between changes in pollution and changes in mortality, allowing for mortality trend and overdispersion with adjustment for time-variant annual mean temperature and temporal auto-correlation in the counts of deaths. We also examined modification of the air pollution effect by time-invariant ecological characteristics such as urbanicity and areal socioeconomic status using interaction terms. Results: In total, 3,122,751 all-cause, 1,173,071 cardiovascular disease (CVD) and 422,703 respiratory disease deaths were analysed. A 10µg/m<sup>3</sup> increase in PM<sub>2.5</sub> was associated with 12.1% (95%CI: 10.5, 13.7), 16.0% (13.3, 18.7) and 16.4% (11.7, 21.4) increase in all-cause, CVD and respiratory disease mortality, respectively after adjusting for temperature and allowing for mortality trend. The effects varied among regions. There was significant effect modification by population density suggesting impacts were limited to highly populated areas. Results for PM<sub>10</sub> were broadly similar with smaller effect size. Conclusions: Our current analysis suggested recent reduction in exposure to ambient fine-particulate air pollution contributes to measurable reduction in mortality in England and Wales.

## O02.03E. Global Health Equity Issues Related to Pesticide Use

### **O02.03.25. The Relationship between Urinary Levels of Dialkyl Phosphates and Reproductive and Anthropometric Development of Boys in the Rural Western Cape in South Africa**

Mohamed Dalvie

*Mohamed A. Dalvie<sup>1</sup>*

*1. School of Public Health and Family Medicine, University of Cape Town, Cape Town, Western Cape, South Africa.*

**Abstract:** Background Many agricultural pesticides currently in use are hormonally active but few previous studies have investigated their effect on the reproductive and anthropometric development of pubertal boys. Objective This study investigated the relationship between urinary dialkyl phosphates and reproductive and anthropometric growth of boys from the rural Western Cape in South Africa. Methods A cross-sectional study of 183 school boys residing on farms and neighbouring non-farming areas was conducted. Measurements included a questionnaire, clinical assessment of sexual maturity development (SMD), anthropometric measurements (height, weight and body mass index), serum reproductive hormones (including luteinizing hormone, follicle stimulation hormone, testosterone and oestradiol) and urinary levels of 3 dialkyl phosphates (organophosphate pesticide metabolites) including di-ethyl, di-methyl and di-methyl triphosphate (DEP, DMP and DMTP). Results The median (interquartile range) of age and sum dialkyl phosphates of the school boys was 12 years (9-13 years) and 68.3 ng/mL (27.9-129.5 ng/mL) respectively. There were consistent, mostly non-significant associations, between urinary levels of dialkyl phosphates and adverse effects on outcomes including SMD, reproductive hormones, anthropometric development. There was a strong positive association and dose response found between BMI > 50th percentile and quartiles of DMTP (odd ratio and confidence interval for highest and lowest quartile: 3.3; 1.2 -9). Conclusion the results provide some preliminary evidence that organophosphate pesticides exposure could adversely affect the body size of school boys and weak evidence of other adverse effects on male reproductive development. These findings require further investigation in a larger longitudinal study with seasonal bio-monitoring for pesticides.

## **O02.03.26. Pesticides in the Urine of Preschool Children from Germany and Their Relevance to Human Health**

*3. Institute for Occupational and Social Medicine, RWTH Aachen University, Aachen, Germany.*

**Abstract:** The general population is exposed to a wide variety of health relevant pesticides which are most commonly used in agriculture and consumer products. Typically used pesticides in Germany are Organophosphate-Insecticides, Pyrethroids, Neonicotinoids and Glyphosate. With the exception of Glyphosate these substances are quickly metabolized in the human body when incorporated. Human Biomonitoring methods offer the possibility to measure the metabolites or the parent compound (Glyphosate) in the urine of exposed individuals. For some pesticides specific biomarkers are available and can be used for a health based risk assessment on the basis of Acceptable Daily Intakes (ADIs). The aims of our study were to estimate the magnitude of children's exposure to pesticides and to compare the calculated daily intake to established health based risk values. 95 children (2-6 yrs) participated in our human biomonitoring study. Overall, 20 metabolites of Organophosphate-Insecticides (8), Pyrethroids (8), Neonicotinoids (4) and Glyphosate as parent compound were measured in the urine of the children. With an established toxicokinetic model, we calculated the intake of Chlorpyrifos, Deltamethrin and Glyphosate in these children. We measured a broad range of exposure to pesticides in our study population. The highest concentrations could be found for Organophosphate metabolites, followed by the metabolites of Pyrethroids and Neonicotinoids. Comparatively low concentrations in the urine could be detected for Glyphosate. The estimated daily intake of Deltamethrin and Glyphosate was below the ADI. Approximately 5 % of the children showed intake values above the ADI for Chlorpyrifos. In conclusion, children in Germany were found to be exposed to different groups of pesticides. By using specific biomarkers we can show that exposure to Chlorpyrifos may pose a public health concern whereas the exposure to Deltamethrin and Glyphosate is below health relevant thresholds.

### **002.03.27. Prospective Association of DDT and DDE Exposure with High Blood Pressure among Adult Women from Mexico**

Lea Cupul-Uicab

*Martha G. Tello-Juarez<sup>2</sup>, Efrain A. Terrazas-Medina<sup>1</sup>, Mauricio Hernandez-Avila<sup>1</sup>, Lea A. Cupul-Uicab<sup>1</sup>*

*2. Epidemiology, School of Public Health, Cuernavaca, Morelos, Mexico.*

**Abstract:** Introduction and Objective High levels of DDT and DDE might increase the risk of developing hypertension among adults; epidemiological evidence however, is unclear. We prospectively assessed whether non-occupational exposure to p,p'-DDE and p,p'-DDT were associated with high diastolic and systolic blood pressure among women from Tapachula, Chiapas, a highly exposed area of Mexico. Methods Levels of p,p'-DDE and p,p'-DDT were determined in serum samples drawn when women were recruited (2002-2003), they were clinically healthy with no prior diagnosis of diabetes and hypertensive disorders at that time. We followed women from the Tapachula cohort (2015-2017); systolic (SBP) and diastolic blood pressure (DBP) of the women (n=253) were measured (mmHg) twice. The risk of having high blood pressure (HBP: SBP>120 and DBP>80 mmHg) was modeled with logistic regression. Results Median levels of DDE were 3.02 µg/g of lipids and of DDT were 0.29 µg/g; 22.5% of the women had HBP. Relative to the least exposed (DDE≤3.00 µg/g), the adjusted odds ratio for women with 3.01-6.00 µg/g was 2.25 (95% CI: 1.1, 4.8); for those with 6.01-9.00 was 1.13 (95% CI: 0.4, 3.5); and for those with the highest exposure (>9.00) was 1.17 (95% CI: 0.5, 2.9). Increasing levels of DDT exposure showed a small positive association with HBP before adjusting, which disappeared after taking into account important confounders. Conclusions Our results provide some support of the potential adverse effect of non-occupational exposure to DDT on high blood pressure in adult population. Women from the Tapachula Cohort were initially healthy with no hypertensive disorder when their exposure was determined; they were also exposed to DDT for various decades.

## **002.03.28. Insecticide Exposure and Wheeze in 5-Year Old Children from the Infants' Environmental Health Study (ISA)**

Berna Van Wendel de Joode

*Berna Van Wendel de Joode<sup>1</sup>, Brooke Alhanti<sup>2</sup>, Ana Maria Mora<sup>1</sup>, Leonel Córdoba<sup>1</sup>, Jorge Ernesto Peñaloza Castañeda<sup>1</sup>, Brian Reich<sup>2</sup>, Manuel Soto-Martinez<sup>3</sup>, Christian Lindh<sup>4</sup>, Jane Hoppin<sup>2</sup>*

**Abstract:** Background: Organophosphate insecticides may affect children's respiratory health, however, data are scarce. We examined whether prenatal and current chlorpyrifos and pyrethroid insecticide exposures were associated with wheeze in children from the Infants' Environmental Health Study (ISA) in Costa Rica. Methods: We interviewed mothers from 5-year old children (mean  $5.5 \pm 0.4$  years) ( $n=303$ ) about children's wheeze during the last 12 months using the ISAAC questionnaire. We measured pesticide metabolite concentrations in maternal urine collected 1-3 times during pregnancy and in children's urine obtained at 5 years: TCP for chlorpyrifos; DCCA for the pyrethroids permethrin, cypermethrin, and cyfluthrin; and 3PBA for permethrin, cypermethrin, and deltamethrin. For each metabolite, we created 'high' and 'low' exposure groups by calculating the 75th percentile of the averaged concentrations during pregnancy, as well as the current concentrations, adjusting for specific-gravity. We ran multivariable separate logistic regression models for prenatal and current pesticide metabolite concentrations (high/low) and wheeze during the last 12 months, adjusting for maternal smoking during pregnancy, child's sex, and parity. Results: Twenty percent of the children had at least one episode of wheeze during the last twelve months. Seventy-fifth percentile prenatal and current concentrations were, respectively: TCP 2.5 and 2.3  $\mu\text{g/L}$ , DCCA 2.4 and 4.5  $\mu\text{g/L}$ , 3-PBA 1.4 and 3.8  $\mu\text{g/L}$ . Current high DCCA concentrations were associated with an increased risk of wheezing OR=2.1 (95%CI 1.1-3.9), whereas prenatal DCCA were not OR=0.7 (95%CI 0.3-1.4). Current high 3PBA concentrations were marginally associated OR=1.7 (95%CI 0.9-3.3), whereas prenatal concentrations were not OR=1.0 (95%CI: 0.5-2.0). Prenatal or current TCP concentrations were not associated with wheeze. Conclusions: Current exposure to pyrethroid insecticides may increase the risk of wheeze in young children.

## **O02.03.29. Pesticides and Lung Health: Pediatric Association between Agricultural Pesticide Use and Respiratory Health in Fresno, California**

**Abstract:** Previous studies suggest that exposure to pesticides may be linked to increased risk of pediatric asthma; however, there is currently insufficient evidence to demonstrate a causal link. We investigated the association between exposure to agricultural pesticide application of three classes of pesticides (organophosphates (OP), carbamates (C), and methyl bromide (MeBr)) and lung function in a pediatric cohort in Fresno, CA, a community with intense agricultural pesticide use and high asthma prevalence. Study participants were members of the Fresno Asthmatic Children's Environment Study (FACES), a cohort of racially and ethnically diverse children recruited from ages 6 - 11 with a physician diagnosis of asthma. We developed the "purexposure" package in R to pull publically available data from the California's Department of Pesticide Regulation and calculate exposure to pesticide application. Exposure to three classes of pesticides was estimated by calculating the kilograms of relevant pesticides applied within a 3,000-meter buffer around each child's home for the year prior to the baseline measure of FEV1. Study participants' baseline measure of forced expiratory volume in the first second (FEV1) was the primary outcome for this analysis. The association between pesticide application and FEV1 was estimated by fitting a generalized linear model controlling for sex, age, height, and weight. Compared to participants in the lowest quartile of pesticide exposure, participants in the highest quartile of exposure demonstrated a positive association between FEV1 and exposure to OP (RR: 1.004, 95% CI: 1.004, 1.018), C (RR: 1.004, 95% CI: 1.004, 1.017), and MeBr (RR: 1.006, 95% CI: 1.007, 1.020). These results do not support our hypothesized harmful association between FEV1 and exposure to pesticides, and suggest that the association between pesticide application and lung function may be confounded by other environmental exposures such as air pollution.

**Abstract:** Background: The Household Air Pollution Intervention Network (HAPIN) Trial is a multi-country effort to demonstrate the effects of a liquefied petroleum gas (LPG) stove and fuel distribution intervention on birthweight, child health, and adult chronic disease. Here we summarize the pilot baseline and post-intervention PM<sub>2.5</sub> exposure measurements from the four field sites, which were conducted to determine the potential of detecting improvements in women and children's health. Methods: 24 and 48-hr personal exposures to PM<sub>2.5</sub> on the primary cook were assessed in Guatemala, India, Peru, and Rwanda. Exclusive use of LPG was strongly encouraged post-intervention to determine the lower end of potential exposures. Specific instrumentation and sampling approaches varied across centers due to logistical considerations during the pilot period, but all used paired before/after designs and gravimetric-based systems. Data in Peru was collected for the Cardiopulmonary Outcomes and Household Air Pollution (CHAP) Trial ([www.ncbi.nlm.nih.gov/pubmed/29100550](http://www.ncbi.nlm.nih.gov/pubmed/29100550)). Results: Mean 24-hr personal exposures were consistently and substantially lower when using LPG compared to biomass for all sites: Guatemala (251 µg/m<sup>3</sup> [n=36] vs 41 µg/m<sup>3</sup> [n=12], 84% reduction); India (125 µg/m<sup>3</sup> [n=40] vs 22 µg/m<sup>3</sup> [n=12], 82% reduction); Peru (119 µg/m<sup>3</sup> [n=49] vs 24 µg/m<sup>3</sup> [n=26], 79% reduction), and Rwanda (210 µg/m<sup>3</sup> [n=35] vs 65 µg/m<sup>3</sup> [n=36], 69% reduction). Conclusions: The range of exposures falls on the steep sections of known exposure-response curves, implying potentially important health benefits with a gas intervention. The exposure reductions are also relatively large compared to those reported for

other household energy interventions, including for some associated with liquid or gas fuels. The results suggest clean fuel interventions may lower exposures to near or below the WHO interim-1 target of 35  $\mu\text{g}/\text{m}^3$ , though efforts to minimize stacking and exposure contributions from other sources remain critical.

### **002.03.32. Initial Household- and Village-Level Impacts of Residential Coal Use Restrictions on Indoor Air Quality in Rural Homes in Beijing, China**

**Abstract:** China is conducting a large-scale replacement of high-polluting, traditional heating stoves in rural areas with electricity- and natural gas-powered clean heating systems due to the contribution of residential coal combustion to air pollution. We conducted a feasibility study among 300 households in three districts in the Beijing Municipality Region to collect baseline information on heating technologies and usage patterns, housing characteristics, and indoor air pollution. In each district, one treatment village (coal restricted and access to heat pump replacement program) and a similar non-treatment village (not coal-restricted and no access to heat pump replacement program) were selected. We measured 24-h indoor concentrations of fine particulate matter (PM<sub>2.5</sub>, 5-min resolution) in a subset of homes in each village (n = 4-6 homes per village) using a laser photometer (DustTrak 8520, TSI Inc, measurements corrected for known light-scattering bias). Hourly outdoor PM<sub>2.5</sub> concentrations were obtained from the nearest environmental air quality monitoring stations in each district, and used to calculate hourly ratios of indoor-to-outdoor (I/O) PM<sub>2.5</sub>, as a means to initially investigate the influence of outdoor and indoor sources of PM. Our preliminary results suggested that the subsidized clean heating technologies replaced coal in 2 of the 3 treated villages and were associated with lower indoor PM<sub>2.5</sub> concentrations. In the 2 treated villages that stopped using coal, geometric mean (95% CIs) 24-h indoor concentrations of PM<sub>2.5</sub> were non-significantly lower compared with untreated homes in the same district [geometric mean [treated: 162 (85,307) µg/m<sup>3</sup> vs. un-treated: 222 (141,351) µg/m<sup>3</sup>]. We also found that the average hourly I/O PM<sub>2.5</sub> ratios were lower in treated homes compared with untreated homes in the same district [treated: 2.7 (1.4, 5.0) vs. un-treated: 3.9 (2.7, 5.5)], suggesting that indoor sources may contribute less to measured indoor PM<sub>2.5</sub> in these homes.

## **002.03.33. Government Policy, Clean Fuel Access, and Persistent Fuel Stacking in Ecuador**

**Abstract:** **BACKGROUND:** There is now strong evidence that exclusive clean cooking fuel use, eliminating all biomass combustion, is necessary to obtain health benefits from reducing exposure to household air pollution. Ecuadorian households have had access to low-cost liquefied petroleum gas (LPG), financed by large direct government subsidies for more than three decades. Here, we evaluate the development of the LPG subsidy and the extent to which it has resulted in shifts to clean cooking. **METHODS:** We describe the development and impacts of LPG subsidies using a mix of methods: 1) review of academic literature, newspapers, and government records; 2) key informant interviews (n=9); 3) surveys conducted in rural, northern Ecuadorian households (n=383) assessing cooking patterns; and 4) focus groups (n=6) in a subset of surveyed households to better characterize survey findings. **FINDINGS:** LPG subsidies were developed for reasons other than direct health or economic benefits gained from transition to clean cooking fuel from biomass combustion. Nonetheless, these efforts have resulted in 90% of Ecuadorian households cooking primarily with LPG. Among the rural households surveyed, LPG use and satisfaction was high, however, more than three-quarters of those surveyed reported weekly woodfuel use. Focus group discussions revealed that LPG accessibility and inconsistent delivery was a persistent barrier to exclusive use among study households. **CONCLUSIONS:** Ecuador provides valuable lessons that can guide current and future national clean fuel programs. This study represents one of the first efforts to describe long-term cooking practices in the presence of low-cost LPG. This study highlights that nationally-representative surveys that measure only "primary cooking fuel" may underestimate solid fuel use as a supplemental household energy, particularly in areas where limited fuel availability plays a stronger role.

### **O02.03.34. Exploring Barriers and Practical Solutions for the Uptake and Use of Clean Cooking through Photovoice Methods: The LPG Adoption in Cameroon Evaluation (LACE) Studies**

Daniel Pope

*Sara Ronzi<sup>1</sup>, Elisa Puzzolo<sup>2</sup>, Lirije Hyseni<sup>1</sup>, James Higgerson<sup>1</sup>, Debbi Stanistreet<sup>1</sup>, Rachel M. Anderson de Cuevas<sup>1</sup>, Bertrand Hugo Mbatchou Ngahane<sup>3</sup>, Nigel Bruce<sup>1</sup>, Daniel Pope<sup>1</sup>*

**Abstract:** Background: Each year up to 4 million people die prematurely from household air pollution due to domestic use of solid fuel, mainly in low and middle-income countries (LMICs). Liquefied Petroleum Gas (LPG) is an affordable, scalable, and widely available clean fuel that provides health and environmental benefits when used for household energy in LMICs. In Cameroon, where 70% of people rely on biomass for cooking, the Government aims to increase LPG use from < 20% to 58% by 2035. Few qualitative studies have explored households' perceptions of factors affecting LPG uptake. We conducted community-based participatory research using photovoice methods to explore factors influencing LPG uptake and sustained use in South-West Cameroon. Methods: Two groups of participants from rural (n=7) and peri-urban (n=8) areas photographed aspects of their lives which prevented/enabled LPG uptake in their communities. Individual interviews (n=15) and group discussions (n=5) explored participants' reflections on the issues photographed. We conducted thematic analysis using NVivo 10 software. Results: Main barriers included difficulty in affording the initial LPG equipment and ongoing refills, scarcity of LPG retail shops and safety concerns. Key enablers/solutions included (i) increasing awareness of the benefits of LPG, (ii) additional retail shops, (iii) addressing safety concerns, (iv) repairing roads to improve distribution, and (v) reducing the refill price. We organised an exhibition of participants' photos to generate discussions between participants and representatives from government, communities, industry and media about how to assist communities with fuel transition. Conclusions: Photovoice was found to be an effective participatory approach that (i) identified factors affecting uptake and use of LPG, which could be transferable to Sub-Saharan contexts, and (ii) engaged with participants and key stakeholders to identify how to advance equitable access to LPG in Cameroon.

## **002.03.35. Effectiveness of Liquefied Petroleum Gas Stove Ownership for Reducing Household Air Pollution Exposure during Pregnancy in Guatemala**

Laura Grajeda

**Abstract:** Background: Household air pollution from solid fuel use has been associated with adverse birth outcomes. Efforts to reduce exposure focused on chimney stoves have had limited success, and switching to liquefied petroleum gas (LPG) fuel is a promising alternative. Moreover, estimating a person's typical exposure has been a challenge in epidemiological studies, due to temporal variability. Objectives: We aimed to estimate the effectiveness of LPG stove ownership for reducing personal exposure to fine particulate matter (PM<sub>2.5</sub>) and describe the between- and within-person variation in exposure during pregnancy. Methods: We recruited women at <20 weeks of gestation in highland Guatemala and measured 24-hour average personal PM<sub>2.5</sub> exposure three times using an impactor with a Teflon filter and a pump. We used linear mixed effects model to estimate the variance components of log PM<sub>2.5</sub>, subject-specific typical personal exposures and the exposure reduction associated with stove ownership. Results: We obtained 559 repeated measurements from 218 pregnant women. Among them, 59 (27%) owned a LPG stove and 379 (68%) owned a chimney stove at recruitment. Typical exposure was 57 µg/m<sup>3</sup> (95%CI: 49-66) and 96 µg/m<sup>3</sup> (95%CI: 87-106) for women with and without an LPG stove, respectively. After adjusting for confounders, LPG stove ownership was associated with 41% lower personal PM<sub>2.5</sub> (95%CI: 27 to 52). Intraclass correlation coefficients was 0.51 (95%CI: 0.42-0.59) overall, and for women with and without LPG stove were 0.46 (95%CI: 0.27-0.62) and 0.46 (95%CI: 0.36-0.56), respectively. Conclusions: Effectiveness of LPG stoves for personal exposure reduction in pregnant women was moderate and might depend largely on the extent of adoption. The relatively high correlation among repeated exposure measures within individuals in this setting suggests that a small number measures per individual can provide a reliable estimation of typical exposure during pregnancy.

### **O02.03.36. Indoor Nitrogen Dioxide in Homes with Biomass Cookstoves before and after a Gas Stove Intervention**

Josiah Kephart

*1. Environmental Health and Engineering, Johns Hopkins University, Baltimore, MD, United States.*

*2. Division of Pulmonary and Critical Care, Johns Hopkins University School of Medicine, Baltimore, MD, United States.*

**Abstract:** Emissions from biomass-fueled cookstoves are the largest environmental contribution to the global burden of disease, responsible for 2.6 million deaths annually. A transition from biomass to liquified-petroleum gas (LPG) cookstoves has been proposed as a global public health intervention. While this transition seems likely to reduce fine particulate matter and carbon monoxide, very little is known about cookstove-related emissions of nitrogen dioxide (NO<sub>2</sub>), a threat to respiratory health. Assessing exposure to NO<sub>2</sub> from biomass and LPG cookstoves is essential to understand the public health risks posed by biomass cookstoves and inform the current promotion of LPG as a healthier alternative to biomass fuel. This study aims to 1) quantify NO<sub>2</sub> exposure from biomass cookstoves and 2) assess changes in NO<sub>2</sub> exposure after the transition from biomass to LPG cookstoves. We will measure NO<sub>2</sub> concentrations in 100 kitchens with biomass cookstoves in rural Puno, Peru. Concentrations will be sampled by direct-reading instruments at one-minute intervals for 48 hours, allowing us to quantify both daily mean concentrations and short-term concentration peaks associated with cooking events. To assess the effect of transitioning from biomass to LPG on kitchen NO<sub>2</sub> concentrations, we will randomize 50 of these households to receive free LPG stoves and fuel and 50 households to serve as a control. We will measure NO<sub>2</sub> concentrations three months post-intervention. In our study setting, homes with biomass cookstoves experienced daily NO<sub>2</sub> concentrations [48-hour mean (sd): 139 ppb (92), n=99] well above the WHO indoor annual guideline (21 ppb). Acute exposures were also elevated, as 26% of kitchen-hours [1-hour mean (sd): 139 ppb (252), n=2376 hours] were above the WHO indoor hourly guideline (105 ppb). Transitioning from biomass to LPG cookstoves reduced daily NO<sub>2</sub> concentrations by 40%, however these concentrations [mean (sd): 73 ppb (47), n=40] remain above the WHO annual guideline (21 ppb).

**Abstract:** Background: Aircraft noise is a key concern for communities surrounding airports, with increasing evidence for cardiovascular health effects. While changes in technology have resulted in quieter aircraft, aviation demand in the U.S. has increased over time with varying patterns by airport and U.S. region. As part of the first longitudinal national-scale compilation of civil aviation noise exposure estimates, we aim to evaluate trends in aviation noise exposure over time in the U.S. Methods: Noise contours were modeled for 90 U.S. airports in 5-year intervals between 1995 and 2015 using the Aviation Environmental Design Tool. We utilized linear fixed effects models to estimate changes in the sizes of exposure areas by U.S. Census regions/divisions with  $\geq 65$  dB or  $\geq 55$  dB day-night average sound level (DNL) corresponding to the current FAA regulatory threshold and a 10 dB lower level for comparison, respectively. We overlaid noise contours and Census block data from the U.S. Census Bureau and American Community Surveys for 2000 to 2015 in a geographic information system to estimate population changes within noise levels. Results: National-scale analyses showed non-monotonic trends in mean exposed areas for  $\geq 65$  and  $\geq 55$  dB DNL over time that peaked in 2000; exposed areas were the largest in the Midwest region from 2000 to 2005. While exposed areas across most regions declined after 2000, only the West region increased from 2010 to 2015. There were notable declines in exposed populations over time; for example exposure in New England decreased by 89% and 56% in total population living within the  $\geq 65$  and  $\geq 55$  dB areas, respectively, from 2000 to 2010. Conclusions: Our analyses reinforce the complex patterns of aircraft noise exposure over time and space across the U.S., with trends affected by the economy/enplanement, airport operations, runway additions, and technology evolution. These data will provide the foundation for cohort studies on aircraft noise and health in the U.S.

## **002.03.38. Exposure to Road Traffic Noise and Cognitive Development in Primary Schoolchildren**

**Abstract:** Exposure to aircraft noise may lead to impaired cognitive performance in schoolchildren, but the evidence for road traffic noise is still limited. We studied the association between long-term exposure to road traffic noise and schoolchildren's cognitive development. We followed-up a population-based sample of 2715 children aged 7-10 years from 39 socioeconomically paired schools in Barcelona (Catalonia, Spain). Children underwent computerized cognitive tests 4 times during one year to assess growth (n = 10112). We assessed working memory (2-back task, detectability), superior working memory (3-back task, detectability), and inattentiveness (Attention Network Task, hit reaction time standard error). Traffic-related noise and air pollution were measured indoors and outdoors at schools, at the start of the school year and 9 months later. Noise was measured with a type II sound level meter using standard protocols to obtain long-term A-weighted average levels (LAeq, in dB). We obtained indoor noise levels in all classrooms by correcting for classroom orientation and change between years. Linear mixed effects models were adjusted for age, sex, maternal education, socioeconomic status, and traffic-related air pollution. Exposure to road traffic noise outdoors at schools was consistently associated with smaller working memory (2-back and 3-back) and greater inattentiveness growth in children. E.g., an interquartile range increase in noise was related to -7.51 points (95%CI: -11.1; -3.91) in 3-back detectability. Exposure to road traffic noise in classrooms was only associated with inattentiveness. Associations were robust to all adjustment sets. Children exposed to greater outdoor levels of road traffic noise at schools exhibited slower cognitive development. Exposure to road traffic noise in classrooms, where noise levels are lower, was associated only with inattentiveness, which might suggest that inattentiveness is a more noise sensitive outcome than working memory.

## **002.03.39. Road Traffic Noise, Air Pollution, and Risk of Dementia: Results from the Betula Project**

**Abstract:** **BACKGROUND:** There is growing evidence for a negative impact of traffic-related air pollution on risk of dementia. But traffic also generates noise, and to our knowledge, the contribution of noise exposure to this association has not been previously examined. **OBJECTIVE:** The aim of this study was to investigate the individual and combined effect of noise and air pollution on risk of dementia. **METHODS:** Data on dementia incidence over a 15 year period was obtained from the Betula project, a longitudinal study on health and ageing. Estimates of annual mean levels of nitrogen oxides (NOx) at the participants' residential address were obtained using a land-use regression model. Modelled data provided road traffic noise levels (Leq 24h) at the participants' residential address at baseline. Cox proportional hazard regression was used to calculate hazard ratios (HR). **RESULTS:** Of 1721 participants at baseline, 302 developed dementia during the follow up period. Exposure to noise levels (Leq 24h) >55dB had no significant effect on dementia risk (HR 0.95; CI: 0.57, 1.57). Residing in the two highest quartiles of NOx exposure was associated with an increased risk of dementia. The risk associated with NOx was not modified by adjusting for noise. Nor did we find any significant interaction effects between NOx and road traffic noise on dementia risk. **CONCLUSION:** We found no evidence that exposure to road traffic noise, either independently or in combination with traffic air pollution, was associated with risk of dementia in our study area. Our results suggest that pollution should be considered the main component in the association between traffic related exposures and dementia. We believe that these result contribute to the growing understanding of the associations between traffic pollution and dementia, which in turn could prove valuable for planning and building sustainable urban environments.

## **O02.03.40. Modeled and Perceived RF-EMF, Noise and Air Pollution and Symptoms in a Population Cohort: Is Perception Key in Predicting Symptoms?**

Marije Reedijk

*Astrid Martens<sup>1</sup>, Marije Reedijk<sup>1</sup>, Tjabe Smid<sup>2</sup>, Anke Huss<sup>1</sup>, Danielle Timmermans<sup>2</sup>, Maciej Strak<sup>1</sup>, Wim Swart<sup>3</sup>, Virissa Lenters<sup>1</sup>, Robert Verheij<sup>4</sup>, Hans Kromhout<sup>1</sup>, Pauline Slottje<sup>2</sup>, Roel Vermeulen<sup>1</sup>*

**Abstract:** Introduction Psychosocial research has shown that perceived exposure can influence symptom reporting, regardless of actual exposure. The impact of this phenomenon on the interpretation of results from epidemiological research of environmental determinants on self-reported health is unclear. Methods In this study we compared associations between modeled exposures, the perceived degree of being exposed to these exposures and reported symptoms (non-specific symptoms, sleep disturbances, respiratory symptoms) for three environmental exposures (radiofrequency electromagnetic fields (RF-EMF), noise, and air pollution) which vary in the degree to which they can be sensorially observed. Participant characteristics, perceived exposures, and self-reported health were assessed with baseline (n=14829, 2011/2012) and follow-up (n=7905, 2015) questionnaires in the Dutch population-based Occupational and Environmental Health Cohort study (AMIGO). Environmental exposures were estimated at the home address using spatial models. Cross-sectional and longitudinal regression models were used to examine the associations between modeled and perceived exposures, and reported symptoms. Results The extent to which exposure sources could be observed likely influenced correlations between modeled and perceived exposure as correlations were moderate for air pollution (rSp=0.34) and noise (rSp=0.40), but less so for RF-EMF (rSp=0.11). Perceived exposures were consistently associated with increased symptom reporting (non-specific, sleep, respiratory). In general, modeled exposures were associated with increased symptom reporting, but these associations were strongly attenuated when perceived exposure was accounted for in the analyses. Discussion Perceived exposure has an important role in symptom reporting. Evaluations of environmental determinants of symptom reporting may result in biased estimates if exposure perception is not taken into account.

### **O02.03.41. Modelled and Perceived Noise Exposure and Psychotropic Medication Use**

Enembe Okokon

*Enembe O. Okokon<sup>1</sup>*

*1. Department of Health Security, National Institute for Health and Welfare, Finland, Kuopio, Finland.*

**Abstract:** Background Road-traffic noise can induce stress which may eventually lead to mental health disorders. Mental health problems of noise have not are scant in research. People perceive noise differently, this may affect the extent to which noise contributes to poor mental health at individual level. This paper aimed to assess relationships between perceived or modelled noise and use of psychotropic medication. **Methods** We conducted a survey to evaluate perceived exposures of residents of the Helsinki Capital Region of Finland to road-traffic noise and the associations of these exposures with sleep disorder, anxiety and depression. Respondents were randomly sampled from the Finnish Population registry and data was collected using a self-administered questionnaire. Associations between subjective (annoyance) or modelled façade-noise levels and mental health outcome indicators were assessed using generalised additive models while controlling for socioeconomic, lifestyle and exposure-related factors. **Results** A total of 7321 respondents returned completed questionnaires. The proportion of respondents with self-rated moderate to severe road-traffic noise exposure showed a linear trend with higher categories of modelled noise. About 15%, 7% and 7% of respondents used sedative, anxiolytic and antidepressant medicaments, respectively, in the year prior to the study. Perceived noise exposure was clearly associated with anxiolytic drug use only, OR=1.41 (95% CI: 1.02 - 1.95). There was suggestive association between modelled noise and anxiolytic or antidepressant use. In respondents without a quiet façade, modelled noise was more definitively associated with antidepressant use. Noise sensitivity did not modify the effect of noise but was independently associated with increased use of all medication. **Conclusion** We observed few associations between noise and psychotropic medication use. Noise sensitivity was found to predict psychotropic medication use independently of noise.

## **O02.03.42. Long-Term Exposure to Community Noise in Relation to Alzheimer's Disease and Related Dementias**

Sara Adar

**Abstract:** Background: Accruing evidence suggests that a relation of noise exposure to dementia is biologically plausible. Yet the association of long-term exposure to community noise with dementia has not been well-studied. Methods: The Chicago Health and Aging Project, a longitudinal cohort study of adults >65 years, assessed participants' cognitive function and collected other data in triennial home interviews (1993-2011). Using a recently validated method, we predicted the likelihood of dementia or mild cognitive impairment (MCI) for each participant at each interview. We also predicted noise at participant addresses in the 5 years preceding each interview using a land use regression model developed with Chicago-based measurements. We used repeated measures logistic regression models to estimate associations of noise with prevalent dementia and prevalent dementia or MCI, adjusting for age, sex, race, smoking, alcohol, physical activity, income, education, neighborhood socioeconomic status, calendar time, and NO<sub>x</sub>. NO<sub>x</sub>, a traffic-related air pollutant, and a potential source of confounding, was estimated using a spatiotemporal model. Our primary models defined dementia as a dementia likelihood >0.5 standard deviations below the mean; we tested other cutoffs in sensitivity analyses. Results: 5,952 participants underwent a total of 13,551 cognitive assessments. In our primary analyses, 12% of participant exams were classified as having evidence of dementia; 44% had evidence of dementia or MCI. From adjusted analyses, we found that an interquartile range difference in noise (2.7 dB) was associated with a 4% (95% CI: 0.98-1.09) higher odds of prevalent dementia and a 5% (95% CI: 1.01-1.10) higher odds of prevalent dementia or MCI. Less stringent cutoffs strengthened the magnitude of the associations with dementia; associations with dementia or MCI remained unchanged. Conclusion: Long-term noise exposure may contribute to mild cognitive impairment and dementia in older adults.

## 002.03H. Phthalate Exposure and Children's Health

### **002.03.43. Exposure to Endocrine Disrupting Chemicals and Maladaptive Behavior during Adolescence**

Jessica Shoaff

**Abstract:** Introduction: Experimental and epidemiologic studies suggest that exposure to endocrine disrupting chemicals (EDCs), including phthalates and phenols, may influence childhood behavior, but the relationship during adolescence has not been studied. Methods: We investigated the association of EDC exposures with maladaptive behavior in 205 adolescent (age 15 yrs) participants in the New Bedford Cohort, a birth cohort study of chemical exposure and neurodevelopment among residents near the New Bedford Harbor Superfund site, Massachusetts. Urine concentrations of biomarkers of phthalates, phenols and related replacement chemicals were quantified with mass spectrometry. Behavior was assessed with the Behavior Assessment System for Children, 2nd edition Teacher Rating Scale, including the Developmental Social Disorders (DSD) scale related to autistic behaviors. Associations were examined using linear (normally distributed outcomes) or negative binomial (over dispersed Poisson distributed outcomes) regression adjusted for multiple potential confounders. Results: 40% of the adolescents were non-white or Hispanic; at birth, 32% were in low income households and 42% had unmarried mothers. Increased urine concentrations of the molar sum of antiandrogen phthalate biomarkers were associated with an increase in Externalizing Behavior, Behavioral Symptoms Index, and DSD and a decrease in Adaptive Skills. E.g., a doubling of urine antiandrogen phthalate biomarkers was associated with increased Externalizing (RR=1.04; 95% CI: 1.01, 1.08) and DSD ( $\beta=1.4$ ; 95% CI: 0.4, 2.5) behaviors. Associations were stronger in males, but not significantly so. Phenols, other phthalates, and replacement chemicals were not associated with adverse behavior. Conclusion: Our findings support that antiandrogen phthalate exposure during adolescence is a potential correlate of maladaptive behavior.

## **002.03.44. Prenatal and Childhood Phthalate Exposure and Pubertal Development: A 15-Year Birth Cohort Follow-Up Study**

**Abstract:** Background: Phthalates are present in many everyday products such as food containers and personal care items, and medical instruments. Prenatal exposure to phthalates may lead to disruption of pubertal development in girls and boys. We aimed to investigate the effect of early life exposure to phthalate esters on pubertal development. Methods: This study included a birth cohort of 437 women and their children between November 2000 to December 2001, there were 143 children followed at 2, 6, 8, 11, and 14 years after birth (2003, 2006, 2009, 2012, and 2016). These women were known to have been exposed to phthalates during pregnancy, and were identified through urine screening during the third trimester. The follow-up examinations for their children included anthropomorphic measurements and evaluation of gender-specific secondary sexual characteristics. A generalized estimating equation model (GEEM) and general linear mixed model (GLMM) analysis were applied. Results: Among the girls, pubic hair development at follow-up was positively associated with maternal urinary concentrations of monoethyl phthalate (MEP) and mono (2-ethyl-5-hydroxyl) phthalate (MEHHP), and total mono (2-ethyl-5-oxohexyl) phthalate (MEHP) at the 5-, 8-, and 11- years stage ( $p < 0.05$  for all). Cervix length, ovary size, Tanner stage, and menarche were all inversely associated with levels of mono-benzyl phthalate (MBzP). Boys' armpit hair development and puberty-related voice changes were positively associated with MBzP; development of pubic hair was positively associated with the maternal total MEHP level. Conclusions: This first through pubertal multiple assessments of 15-year pre-birth cohort follow-up study showed early life exposure to phthalates had positive association with secondary sexual characteristics in general and negative association with sexual organ growth in general.

## **002.03.45. Associations of Maternal Pregnancy Urine Estrogen Levels with Phthalate and Phthalate Replacement (1,2-Cyclohexane Dicarboxylic Acid Diisononyl Ester, DiNCH) Metabolites**

**Abstract:** Rationale: Pregnant women are exposed to phthalates in food, personal care and household products. Phthalates alter estrogen levels in experimental models but their potential to impact levels in human pregnancy is not well characterized. Methods: 291 participants in an Illinois pregnancy cohort collected 5 urines across pregnancy for pooling and quantification of 16 phthalate/DiNCH metabolites. Exposures were expressed as the molar sum of metabolites for:  $\Sigma$ DiNCH,  $\Sigma$ DEHP,  $\Sigma$ DBP,  $\Sigma$ DiBP,  $\Sigma$ DiNP,  $\Sigma$ PCP, and  $\Sigma$ AA (respective personal care product and anti-androgenic phthalates). At 10-14, 28-30 and 34-36 gestational weeks (GW), urine estradiol, estrone, estriol and metabolites were measured and summed ( $\Sigma$ E). Specific gravity adjusted exposure and  $\Sigma$ E data were log-transformed. Linear mixed-effects models assessed relationships of phthalates/ $\Sigma$ DiNCH with  $\Sigma$ E controlling for fetal sex, maternal age, pre-pregnancy BMI,  $\Sigma$ E analytic batch, and GA at urine collection for  $\Sigma$ E evaluation. Interactions of phthalates/ $\Sigma$ DiNCH, fetal sex,  $\Sigma$ E batch, and GA at  $\Sigma$ E urine collection were explored. Results: Participants were 82% white, 72% had income >\$60,000/yr, 84% had a college+ education, and urine biomarker levels were similar to U.S. women. At 10-14 weeks,  $\Sigma$ E increased with increasing:  $\Sigma$ DBP (b=1.5, 95% CI=0.5, 2.5),  $\Sigma$ DiNP (b=1.3, 95% CI=0.6, 2.0),  $\Sigma$ PCP (b=0.5, 95% CI=0.1, 0.8), and  $\Sigma$ AA (b=0.4, 95% CI=0.01, 0.7); associations in late pregnancy were attenuated and non-significant.  $\Sigma$ E increased with increasing  $\Sigma$ DEHP in women carrying females (b=0.7, 95% CI=0.2, 1.3) and  $\Sigma$ DiBP in women carrying males for  $\Sigma$ E measured in only one analytic batch.  $\Sigma$ E was not associated with  $\Sigma$ DiNCH. Conclusions:  $\Sigma$ DBP,  $\Sigma$ DiNP,  $\Sigma$ PCP, and  $\Sigma$ AA phthalates were associated with higher gestational  $\Sigma$ E in early but not later pregnancy. For other phthalates, associations were only in small sub-group analyses. Whether pregnancy estrogen levels mediate associations between phthalates and pregnancy outcomes merits investigation.

## **O02.03.46. Mixed Phthalate Ester and Phosphate Flame Retardant Exposure and Asthma and Allergies in School Children**

Atsuko Araki

*Atsuko Araki<sup>1</sup>, Yu Ait Bamai<sup>1</sup>, Michiel Bastiaensen<sup>2</sup>, Nele Van den Eede<sup>2</sup>, Toshio Kawai<sup>3</sup>, Tazuru Tsuboi<sup>3</sup>, Sachiko Itoh<sup>1</sup>, Chihiro Miyashita<sup>1</sup>, Adrian Covaci<sup>2</sup>, Reiko Kishi<sup>1</sup>*

*1. Center for Environmental and Health Sciences, Hokkaido University, Sapporo, Japan.*

*2. Toxicological Center, University of Antwerp, Antwerpen, Belgium.*

*3. Japan Industrial Safety and Health Association, Osaka, Japan.*

**Abstract:** Background: Phthalate esters (PEs) and phosphate flame retardants (PFRs) are widely used in interior materials and consumer products. We have reported individual associations between PE and PFR metabolites in urine and children's asthma and allergies, but mixed PEs and PFRs have not yet been studied. Thus, we aimed to find the association between mixed PEs and PFRs and asthma and allergies. Methods: Elementary school children participated in this study. Six PE metabolites were measured using gas chromatography-mass spectrometry (MS); 13 PFR metabolites were measured using liquid chromatography-tandem MS. Wheezing, rhino-conjunctivitis (RC), and eczema were evaluated using International Study of Asthma and Allergies in Childhood questionnaires. Associations between PE and PFR mixtures, and asthma and allergy risk were studied using weighted quantile sum (WQS) regression models adjusted for sex, grade, dampness index, annual house income, parent allergy history, and urine creatinine. Estimated weights of PEs and PFRs as WQS indexes were obtained. The sums of  $\geq 2$  metabolites were calculated as parent compound exposure. Results: Wheezing, RC, eczema, and allergies were prevalent in 29, 46, 36, and 72 of 128 children, respectively. The highest correlations were shown with 5-OH-EHDPHP and  $\Sigma$ TPhP (Spearman's  $\rho=0.525$ ,  $p<0.001$ ), and 5-OH-EHDPHP and  $\Sigma$ TCIPP ( $\rho=0.451$ ,  $p<0.001$ ). WQS index quartile increases showed higher odds ratios (ORs) of RC (OR=2.83; 95% confidence interval=1.28-6.64), eczema (2.71; 1.19-6.58), and any such allergies (6.25; 2.22-20.68). Top three heavily weighted chemicals were as follows: RC, BDCIPP ( $w=0.306$ ),  $\Sigma$ TCIPP (0.311),  $\Sigma$ TBOEP (0.203); eczema, 5-HO-EHDPHP (0.287),  $\Sigma$ TBOEP (0.251), BDCIPP (0.168); and any allergies, BDCIPP (0.383),  $\Sigma$ TBOEP (0.207),  $\Sigma$ TCIPP (0.156). Conclusion: We found positive associations between mixed PE and PFR exposure and allergies risk. TCIPP, TBOEP, EHDPHP, and TDCIPP are the main chemicals that affect allergic symptoms in children.

## **O02.03.47. Prenatal Exposure to Phthalates and Sex Hormone Levels among Adolescent Boys in the CHAMACOS Birth Cohort Study**

Lesliam Quiros-Alcala

*Lesliam Quiros-Alcala<sup>2</sup>, Kim G. Harley<sup>1</sup>, Stephen A. Rauch<sup>1</sup>, Robert H. Lustig<sup>3</sup>, Nina T. Holland<sup>1</sup>, Brenda Eskenazi<sup>1</sup>*

*1. Center for Environmental Research and Children's Health, University of California, Berkeley, CA, United States.*

*2. Maryland Institute of Applied Environmental Health, University of Maryland, College Park, MD, United States.*

*3. Department of Pediatrics, University of California, San Francisco, San Francisco, CA, United States.*

**Abstract:** Background: Phthalates are synthetic compounds widely used in consumer products, including plastics, building materials, and personal care products. Emerging evidence indicates that exposure to these endocrine disrupting compounds could alter reproductive hormones; however, human studies examining in utero exposures are sparse. We examined the associations of prenatal phthalate exposure and reproductive hormones among Latino adolescent boys participating in the longitudinal CHAMACOS birth cohort. Methods: We measured concentrations of 11 phthalate metabolites in maternal prenatal urine. Concentrations of luteinizing hormone (LH), follicle stimulating hormone (FSH), and testosterone were measured in fasting blood samples collected from 110 boys at age 12. Linear regression models examined associations between phthalate metabolites and reproductive hormones, adjusting for income, maternal education, prenatal BMI, and child's age at the 12-year visit. Results: The geometric mean (GSD) of the boys' hormone levels was 2.5 mIU/mL (1.7) for FSH, 1.7 mIU/mL (3.3) for LH, and 66.6 ng/dL (4.2) for testosterone. A two-fold increase in MCBzP and MCPPE concentrations was associated with a respective 15.8% (95%CI: 0.6, 33.3) and 19.8% (95%CI:0.1, 43.4) increase in LH and a 27.3% (95%CI: 5.0, 54.3) and 42.7% (95%CI: 17.0, 74.1) increase in testosterone. A two-fold increase in MCNP, MCOP, MEHP, MECPE, and MEOHP was associated with 28.8% (95%CI:0.2, 65.5), 28.7% (95%CI:4.8, 58.1), 21.3% (95%CI:1.7, 44.7), 25.3% (95%CI:1.8, 54.2), and 22.1% (95%CI:0.8, 47.9) increases in testosterone. Conclusion: Prenatal exposure to phthalates, particularly high molecular weight phthalates, is related to higher levels of reproductive hormones in 12-year old boys, suggestive of earlier onset of puberty.

## 002.03.48. Early Life Exposure to Phthalates in CHILd: A Multi-City Canadian Birth Cohort

**Abstract:** Phthalates, used as plasticizers and solvents, are ubiquitous in the environment. Phthalate exposure has been associated with adverse health effects including childhood asthma and allergic disease. Few studies have examined exposure to phthalates during early life particularly in infancy, a critical window for development. The Canadian Healthy Infant Longitudinal Development (CHILd) Study, a population-based birth cohort, has examined multiple environmental exposures during early life. The goal of this study was to characterize exposure to phthalates during infancy and early childhood in representative participants in the CHILd Study. Pregnant mothers were enrolled 2009-2012 across 4 cities and 1 rural area in Canada. Urine samples were collected at 3, 12 and 36 months of age and, in the first 1,578 children, analyzed for eight phthalate metabolites. Questionnaires were administered at each time point documenting the home environment and maternal and infant behaviours. Geometric mean (GM) metabolite concentrations were calculated at each age. Trends with age and factors that may influence urinary phthalate concentrations were examined using mixed models. Variability between all three measurements were assessed using intraclass correlation coefficients (ICC). Results indicated widespread exposure to phthalates. The highest urinary concentration was for the metabolite MBP at all time points (GM: 15-32 ng/mL). Concentrations of all phthalate metabolites significantly increased with age from 3 to 36 months. Low ICCs were observed for all metabolites (0 to 0.2), suggesting a high degree of variability between measurements from the same child at different ages. There were differences in urinary concentrations of MEP, MBP, MBzP, MCPP depending on study site and urinary MBzP concentrations decreased with mother's age. These data, which will be explored in detail in this presentation, describe widespread exposure to phthalates across a representative sample of the CHILd Study.

## 002.03I. Source-Specific Air Pollution Exposures and Health

### 002.03.49. Improved Air Quality Saved Lives: A Mediation on Particulate Matters

Ana Rappold

*Geoffrey C. Peterson<sup>1</sup>, Anne Corrigan<sup>1</sup>, Christian Hogrefe<sup>1</sup>, Lucas Neas<sup>1</sup>, Rohit Mathur<sup>1</sup>, Ana G. Rappold<sup>1</sup>*

*1. U.S. Environmental Protection Agency, Chapel Hill, NC, United States.*

**Abstract:** Background: In the United States, cardiovascular mortality rates have declined along with improvements in air quality. Between 1990 and 2010, cardiovascular mortality decreased by 45.66% (standard error SE=0.02%) while fine particulate matter (PM<sub>2.5</sub>) exposures decreased by 29.5% (SE=0.2%). We investigate the extent to which reductions in cardiovascular mortality rates can be attributed to reductions in PM<sub>2.5</sub>. Methods: We obtained cardiovascular standardized mortality rates (SMR) for 2132 counties from the US National Center for Health Statistics between 1990 and 2010. We use the Community Multiscale Air Quality model to calculate population-weighted annual average PM<sub>2.5</sub> concentrations for each county. We adapt mediation analysis to calculate the PM-related cardiovascular mortality rates. We examine which PM components and their emission sources contribute most to PM<sub>2.5</sub>-related mortality. Results: Between 1990 and 2010, cardiovascular SMR related to total PM<sub>2.5</sub> decreased by 12.3 (SE=0.4) deaths per 100,000 person-years, approximately 6.5% (SE=0.2%) of the overall decrease in cardiovascular SMR. Reduction in particulate sulfate levels, driven by reductions in sulfur dioxide emissions, mediated 10.8 (SE=0.6) cardiovascular SMR. Per unit mass of emissions, reduction in elemental carbon is most efficient at 1.20 (SE=0.10) cardiovascular SMR per metric kiloton. Emissions of elemental carbon from mobile vehicles have significantly decreased, while emissions from wildland fires and other area sources have increased. Conclusions: Particulate sulfates contribute the most to total PM<sub>2.5</sub>-related cardiovascular mortality, but reductions in carbon was more efficient at reducing PM<sub>2.5</sub>-related cardiovascular mortality. The statements in this abstract do not necessarily reflect the views of the EPA.

## **002.03.50. Health Risk of Living near a Coal Electric Power Plant: A Residential Cohort Study in North-Western Italy**

Fabrizio Minichilli

*Fabrizio Minichilli<sup>1</sup>, Michele Santoro<sup>1</sup>, Elisa Bustaffa<sup>1</sup>, Alessio Coi<sup>1</sup>, Caterina Minniti<sup>1</sup>, Maria Cristina Imiotti<sup>1</sup>, Liliana Cori<sup>1</sup>, Fabrizio Bianchi<sup>1</sup>*

**Abstract:** In North-Western Italy, an Electric Power Plant (EPP) has been active since the early 1970s. In 2014, two production sections fed by coal were seized by the Prosecutor's Office, while a section powered by natural gas is still functioning. To evaluate the association between exposures of residents in an area affected by EPP's emissions and the risk of hospitalization and mortality a population-based cohort study was conducted (follow-up 2001-2013, 1,418,000 person-years). Lympho-hematopoietic and lung cancers, nervous system, cardiovascular and respiratory diseases were analysed. The diffusion of SO<sub>2</sub> and NO<sub>x</sub> was estimated for the main sources of pollution (EPP, other industries, roads, port areas and urban heating) using the MOLOCH-ABLE-ADMS model. Modelled concentrations of SO<sub>2</sub> were used as proxy of residential exposure to air pollution of EPP (SO<sub>2</sub>-EPP); NO<sub>x</sub> was used as proxy of Multi-Source Model including all sources of pollution (NO<sub>x</sub>-MSM). For males (M) and females (F) Hazard Rate Ratios (HRR) adjusted by age, socio-economic deprivation and NO<sub>x</sub>-MSM were computed according to quartiles of SO<sub>2</sub>-EPP concentrations. Linear Trend of HRR was performed (THRR). Mortality analysis showed increased risk for all cancers [THRR-M 1.15 95%CI (1.11-1.19); THRR-F 1.10 95%CI (1.11-1.19)], lympho-hematopoietic cancers [M 1.30 (1.14-1.48); F 1.17 (1.01-1.35)], nervous system [M 1.10 (1.00-1.22); F 1.12 (1.02-1.22)], cardiovascular [M 1.11 (1.07-1.16); F 1.16 (1.12-1.20)], and respiratory diseases [M 1.23 (1.13-1.33); F 1.17 (1.07-1.27)]. Results of hospitalization analysis were largely consistent with those of mortality analysis. The risk excesses associated to exposures attributed to the coal plant have been obtained for mortality or hospitalization causes for which the evidence of association with atmospheric emissions is persuasive. The results reinforce the knowledge on the dangers of the use of coal for energy production and the consequent indication to decarbonise to protect health.

### **O02.03.51. Preterm Birth among Infants Exposed to in Utero Ultrafine Particle Emissions from Aircraft Engines near the Los Angeles International Airport**

Sam Wing

*1. Epidemiology, UCLA, Los Angeles, CA, United States.*

*2. Environmental Health, USC, Los Angeles, CA, United States.*

**Abstract:** Ambient air pollution is a known risk factor for adverse birth outcomes, but the role of ultrafine particles (UFPs) is not yet well understood. UFP emissions from aircraft are spread across large residential areas downwind of airports, possibly causing a considerable reproductive health burden. Birth certificate data from the California Department of Public Health was drawn from all births by mothers living in a 200 mi<sup>2</sup> area downwind of Los Angeles International Airport (LAX) in 2011 (n=16,268). These records were used to ascertain the presence preterm birth (PTB), as well as maternal covariate information. To assess in utero exposure to UFPs, we input geocoded maternal addresses into a novel geospatial UFP dispersion model that has been validated by extensive ground-level measurements near LAX. We used multiple logistic regression, regressing PTB (live birth < 37 weeks gestation) on UFP concentrations estimated from the dispersion model. We adjusted for maternal factors like age, educational attainment, and race/ethnicity. We further adjusted for measures of air pollution from other sources, like traffic, including PM<sub>2.5</sub>, nitrogen oxides, and surface ozone to isolate the role of aircraft-related UFPs. An interaction term between UFPs and maternal nativity was included in the model. Among this birth cohort, we found an 11% increase in odds (95% CI: 1.01, 1.22) of PTB per interquartile range of UFP exposure. When stratified by maternal nativity, no increase in PTB among infants of foreign-born mothers was detected (OR = 1.02, 95% CI: 0.90, 1.16) but was detected among infants of US-born women (OR = 1.19, 95% CI: 1.06, 1.32). Effect modification by nativity was borderline statistically significant (p = 0.04). We found increased exposure to aircraft-related UFPs was associated with an elevated risk of PTB, serving as evidence of the reproductive health effects of UFP exposures from aircraft emissions. However, this relationship appears to be modified by maternal nativity.

## **002.03.52. Integrative Strategy for Finding Co-Location Patterns between Adverse Birth Outcomes and Industrial Air Pollution**

Charlene Nielsen

*Charlene Nielsen<sup>4</sup>, Jesus Serrano-Lomelin<sup>2</sup>, Shazan Jabbar<sup>3</sup>, Osnat Wine<sup>1</sup>, Colin Bellinger<sup>3</sup>, Osmar Zaiane<sup>3</sup>, Alvaro Osornio Vargas<sup>1</sup>*

**Abstract:** The relationship of many hazardous pollutants present in ambient air with adverse birth outcomes (ABO) is still unknown, particularly from those released by industry. The knowledge gap is even greater when considering the impact of mixtures of hazardous pollutants on pregnancy outcomes. We aimed to collaboratively overcome methodological limitations to identify potential hazardous mixtures of industrial air pollutants spatially related to the occurrence of ABO in Alberta. We applied integrative data analyses on large existing databases (2006-2012) from (i) the National Pollutant Release Inventory on chemicals released into air by industry; (ii) the Alberta Perinatal Health Program on births, known maternal risk factors for ABO, and the maternal postal code at birth; (iii) an area-level socioeconomic status index (SES). We developed a novel spatial data mining (DM) algorithm to identify significant spatial colocation rules of combinations of emitted chemicals and ABO (i.e., preterm birth [PTB], small for gestational age [SGA], and low birth weight at term [LBWT]). We used a Geographic Information System (GIS) to assign exposures to residences within 10 km of emission sites. We used epidemiological analysis to calculate the corresponding odds ratios of exposures to chemical mixtures and the occurrence of ABO, adjusted by maternal covariates and SES. DM distinguished five rules combining three chemicals - gases, particulate matter and organics - associated with ABO. GIS assigned exposure and epidemiological analysis identified all rules with increased odds for induced PTB, four for SGA, and only two for LBWT. The combined interdisciplinary use of data mining, GIS, and epidemiology strategies enabled us to generate new hypothesis by identifying the risks associated with mixtures of hazardous chemicals and ABO - findings that proved elusive when applying methodologies individually. These discoveries enhance our understanding of the role of chemical mixtures in ABO.

### **002.03.53. Associations of PM2.5 Source Concentrations with Childhood Asthma Emergency Department Visits in the U.S. State of Georgia: A Case-Crossover Study**

Mengjiao Huang

*Mengjiao Huang<sup>1</sup>, Cesunica Ivey<sup>2</sup>, Yongtao Hu<sup>3</sup>, Heather Holmes<sup>4</sup>, Matthew Strickland<sup>1</sup>*

*3. School of Civil and Environmental Engineering, Georgia Institute of Technology, Atlanta, GA, United States.*

*4. Department of Physics, Univeristy of Nevada, Reno, NV, United States.*

**Abstract:** Background A novel hybrid air quality model that provides complete spatial coverage of PM2.5 source concentrations throughout the U.S. State of Georgia was used to investigate associations of air pollution sources with childhood asthma exacerbations. Objectives Estimate and compare associations of 12 PM2.5 source concentrations (i.e., contributions of emissions from motor vehicles, power plants, etc. on PM2.5 concentrations) with childhood asthma Emergency Department (ED) visits. Methods ED visits for asthma or wheezing (N=122,414) among children and adolescents (age ≤18 years) were obtained from patient claims records (in 2005 and 2007). Daily average PM2.5 concentrations from 12 sources were estimated using a hybrid chemical transport (CTM)-receptor model fused with observations from stationary monitors. In the case-crossover study, odds ratios for 3-day moving average PM2.5 concentrations were estimated using conditional logistic regression, matching on day-of-week and month, and adjusting for average temperature (3-day moving average), water vapor mixing ratio (3-day moving average), and Federal holidays. Results We observed positive associations between several PM2.5 sources and asthma ED visits. For example, per interquartile range increase in the source contribution, odds ratio estimates were 1.014 (95% CI: 1.008, 1.020) for dust; 1.029 (95% CI: 1.020, 1.039) for metals, and 1.044 (95% CI: 1.027, 1.063) for natural gas. These sources comprise 5.2%, 2.2%, and 6.5% of total PM2.5 mass, respectively. Heterogeneity in odds ratios across sources could reflect differences in the importance of sources in triggering asthma exacerbations. Because the CTM has uncertainties in the emissions and meteorology inputs and in the modeling of atmospheric processes, such conclusions are tentative. Conclusions Short-term increases in the concentrations of PM2.5 from several sources were associated with increases in childhood asthma ED visits.

## **O02.03.54. Long-Term Exposure to Industrial Air Pollution Emissions and the Incidence of Childhood Asthma: The Use of a Population-Based Birth Cohort and Dispersion Modeling**

Audrey Smargiassi

**Abstract:** Studies on the effects of ambient air pollution have mostly focused on road traffic emissions and have mainly been performed in urban areas. We assessed the association between exposure to ambient concentrations of fine particles (PM<sub>2.5</sub>) and sulfur dioxide (SO<sub>2</sub>) resulting from industrial emissions and asthma onset in children of the province of Quebec, Canada. We used a population-based birth cohort developed from administrative health databases that comprised all children born in Quebec between March 2002 and March 2011. Using industrial emissions reported to the National Pollutant Release Inventory and hourly meteorology, we modelled yearly ambient SO<sub>2</sub> and PM<sub>2.5</sub> concentrations with the dispersion model CALPUFF at a fine spatio-temporal scale. Separately for each pollutant, we assessed associations between modelled yearly concentrations of PM<sub>2.5</sub> and SO<sub>2</sub> at the residence of children and the onset of asthma using Cox model with age as the timescale, adjusted for sex, calendar year and Pampalon's material and social deprivation index. The cohort includes 722,667 children of whom 66,559 developed asthma between 2002 and 2011. Preliminary analyses using yearly exposure estimates from 2009-2010 and including 18,392 incident cases of asthma showed positive association for both air pollutants. For an increase equal to the median of SO<sub>2</sub> and PM<sub>2.5</sub> levels, mean percentage changes in the risk of asthma onset was 5.7% (95%CI: 5.2, 6.2%) and 1.6% (95%CI: 1.2, 2.1%), respectively. However, departure from linearity was noted toward the highest levels of exposure. Future work will include additional years of exposure and indirect adjustment for secondhand smoke exposure. The independence of effects of industrial emissions from those of regional background pollutant levels also deserves further consideration. **Acknowledgments:** This work was supported by a contract with Health Canada.

## S02.03A. Advances in Assessment of Dermal Exposures and Absorption

### S02.03.01. Exploring the Use of Dermal Maximum Flux for Chemical Risk Assessment

Adam Griffiths

*Adam Griffiths<sup>1</sup>*

*1. Health Canada, Ottawa, ON, Canada.*

Abstract: Under Canada's Chemicals Management Plan, numerous assessments have been published over the last decade often including quantitative estimation of dermal exposure. Dermal exposures are often drivers of overall exposure. Dermal absorption is a key parameter for refining such exposure estimates. While chemical-specific empirical absorption data are preferred, such data are often lacking and approaches to estimate dermal absorption are often considered. One such approach is the Dermal Maximum Flux ( $J_{max}$ ) Approach.  $J_{max}$  is the steady-state flux of a substance across the skin when present at its solubility limit in the applied vehicle. It is calculated using the dermal permeability coefficient ( $K_p$ ) and the solubility of a substance both in the same vehicle.  $J_{max}$  is combined with the contact area and exposure duration of a given scenario in a risk assessment to calculate a theoretical upper-bound amount absorbed ( $Q_{max}$ ). The Dermal  $J_{max}$  Approach has been gaining traction in the literature due to its alleged conservatism, with some validation having been conducted for cosmetics and fragrances. To further explore the potential suitability of this approach from a regulatory perspective, a large-scale analysis will be presented comparing calculated  $Q_{max}$  values to around 1500 empirical amounts absorbed compiled from the publicly available literature for around 280 substances, spanning a wide range of chemical classes. The presenter will also discuss the utility of the Dermal  $J_{max}$  Approach as an alternative approach, including criteria for its application in human health risk assessments.

### **S02.03.02. Approaches to Assess Dermal Exposure and Absorption within U.S. EPA's Office of Pollution Prevention and Toxics (OPPT)**

Eva Wong

*Eva Wong<sup>1</sup>, Cathy Fehrenbacher<sup>1</sup>, Charles Bevington<sup>1</sup>, Susan Laessig<sup>1</sup>, Chris Brinkerhoff<sup>1</sup>, Daniel Chang<sup>1</sup>*

*1. OPPT, US EPA, Washington, DC, United States.*

Abstract: US EPA's Office of Pollution Prevention and Toxics (OPPT) assesses worker, general population, and consumer exposures to industrial chemicals in its new and existing chemicals programs under the Frank R. Lautenberg Chemical Safety in the 21st Century amendments to the Toxic Substances Control Act (TSCA). When evaluating chemical uses, OPPT uses measured data if available, modeling approaches, or a combination of both to estimate exposures. Activities during manufacturing, processing and use of industrial chemicals can result in dermal exposure to workers whereas use of consumer products and articles can result in dermal exposures to consumers in residential settings. In the absence of measured data for dermal exposure, assessments are often based on modeled estimates. Depending on the chemical specific data available, models that may be utilized for estimating potential dermal exposure include the Chemical Screening Tool for Exposures and Environmental Releases (ChemSTEER) in combination with generic scenarios, the Exposure and Fate Assessment Screening Tool (EFAST) or the newly updated Consumer Exposure Model (CEM). In the absence of dermal absorption data, potential absorption of the chemical from the skin can be based on data for analogous chemicals or on the chemical's physicochemical properties. This presentation provides an overview of approaches and available models for assessing dermal exposures within OPPT. The views expressed in this abstract are those of the authors and do not represent Agency policy or endorsement.

### **S02.03.03. Development of a Mechanistic in Silico Multiscale Framework to Assess Dermal Absorption of Chemicals**

Jan Urbanus

*Jan Urbanus<sup>1</sup>*

*1. Shell Health - Risk Science Team, Brussels, Belgium.*

Abstract: Available models for prediction of dermal exposure of increasing complexity will be discussed for use in regulatory chemical risk assessment, along with a characterization of the model data requirements and model limitations, and a work flow will be recommended to address the needs of the chemical risk assessment and in particular of the need to demonstrate safe use where internal exposure following dermal uptake remains below the target level.

#### **S02.03.04. Evaluation of in Silico Tools for Dermal Absorption Prediction**

**Abstract:** A comprehensive literature search was performed identifying and describing existing in silico models to predict skin absorption. The search was performed on Scopus, PubMed and Toxline. A total of 2212 publications on the subject were identified. Then a two-tiered approach was applied to assess relevance of the publications, starting with an evaluation of title and abstract followed by a review of the full text. From 142 original research publications considered relevant after scientific review, a list with a total of 175 potentially reconstructable models was collected. The majority of models (78 %) were developed to predict dermal absorption of single substances and 38 models were identified predicting absorption of substances from simple mixtures. The models were based on a large number of different descriptors. A set of 11 models was selected to be evaluated regarding their ability to predict dermal absorption of pesticides. The selection comprised different types of models: single substance and mixture algorithmic models, single substance and mixture Artificial Neural Network models, and a single substance comprehensive transient model. The models were implemented based on the active substances'/products' physical/chemical information listed in EFSA's publicly available dataset. For some models additional descriptors had to be computed. To assess the accuracy of the computed predictions, the results of each model were compared to their respective in vitro results from the dataset (sample size up to 6842, depending on model). Model averaging of the full or of a selected set of models is examined as an alternative approach for more accurate predictions. The influence of a range of factors on the predictive quality of the models is assessed. Finally, the potential applicability of the evaluated models in a regulatory framework for evaluating systemic exposure to pesticides via the dermal route is discussed. Project funded by EFSA (OC/EFSA/PRAS/2016/02)

## **S02.03.05. New Developments Concerning Measurements of Occupational Dermal Exposures**

Dag Rother

*Dag Rother<sup>1</sup>*

*1. Unit - Exposure Scenarios, German Federal Institute for Occupational Safety and Health, Dortmund, Germany.*

Abstract: The results of two projects initiated and funded by BAuA on measurement of occupational dermal exposure will be presented. One project is SysDEA (Systematic analysis of dermal exposure to hazardous chemical agents at the workplace). It is in essence a comparative study of different measurement methods for occupational dermal exposures under highly standardized conditions. The overall objective of this study was to generate scientific knowledge that forms the basis for improvements and standardization of measurement methods for dermal exposure to chemicals at the workplace. For more information regarding SysDEA you can check the relevant homepage: <https://www.baua.de/EN/Tasks/Research/Research-projects/f2349.html> The other project is also a comparative study on dermal and inhalation exposure of workers and bystanders during pest control of Oak Processionary Moth (OPM) by spray application. (Existing exposure data from plant protection activities in orchard or vineyards did not seem suitable for extrapolation to oak trees (which may be >20 m)). Also for the OPM-project information is online available: <https://www.baua.de/EN/Tasks/Research/Research-projects/f2343.html>

## S02.03B. Embracing Complexity: Frontiers in High-Resolution Air Pollution Exposure Assessment

### **S02.03.07. Estimating Human Exposure to Air Pollution in High Rise Cities: The Hong Kong D3D Study**

Benjamin Barratt

*Benjamin Barratt<sup>1</sup>, Robert Tang<sup>4</sup>, Martha Lee<sup>3</sup>, Paulina Wong<sup>4</sup>, Ryan Allen<sup>2</sup>, Poh-Chin Lai<sup>4</sup>, Linwei Tian<sup>4</sup>, Thuan Q Thach<sup>4</sup>, Michael Brauer<sup>3</sup>*

2. *Simon Fraser University, Vancouver, BC, Canada.*
3. *University of British Columbia, Vancouver, BC, Canada.*
4. *University of Hong Kong, Hong Kong, Hong Kong.*

Abstract: High density high rise cities have become a more prominent feature globally and air quality is a significant public health risk in many of these cities. As the spatial resolution of exposure assessment at ground level improves, there is an increased need to better understand vertical variation in air pollution, or risk overestimating the exposure of those who live on higher residential floors. Results will be presented from the Hong Kong D3D Study, which aimed to combine (i) a bespoke two dimensional air pollution model, (ii) a comprehensive vertical pollutant monitoring campaign within urban street canyons and (iii) a travel behavior survey to create a dynamic three dimensional (3D) population exposure model. A staged approach was used to quantify mortality risk estimates for an elderly cohort of 66,000 Hong Kong residents. The results from the study provided the first evidence that considering air pollution exposure in a dynamic 3D landscape would benefit epidemiological studies. Higher hazard ratios and a greater number of significant associations were found between mortality and pollutant exposures that would not have found had standard 2D exposure models been used. Dynamic models can also identify differential exposures between population subtypes. Improved urban building design appears to be stimulating the dispersion of local transport related air pollutant emissions in street canyons. Conversely, infiltration factors found in naturally ventilated buildings were high and residences provided little protection from ambient air pollution. This study demonstrated the benefits of dense sensor networks for characterizing human exposure in epidemiological studies. However, shortcomings of sensor technology were also found, where certain sensor types fell short of the required accuracy and precision to detect subtle gradients in pollution levels.

### **S02.03.08. Spatial Patterns of Exposures to Nontraditional Pollutants: Source Resolved Organic Aerosol and Ultrafine Particles**

Albert Presto

*Albert Presto<sup>1</sup>, Hugh Z. Li<sup>1</sup>, Ellis S. Robinson<sup>1</sup>, Peishi Gu<sup>1</sup>, Provat Saha<sup>1</sup>, Rishabh U. Shah<sup>1</sup>, Joshua S. Apte<sup>2</sup>, Allen L. Robinson<sup>1</sup>*

*1. Carnegie Mellon University, Pittsburgh, PA, United States.*

*2. University of Texas, Austin, TX, United States.*

**Abstract:** Background: Quantification of spatial variations in air pollutant concentrations often focus on time-integrated samples of EPA criteria pollutants such as NO<sub>2</sub> and PM<sub>2.5</sub>. This approach does not directly inform the sources driving variations in pollutant concentrations, nor does it capture sub-daily temporal variations characteristic of dynamic pollutants such as ultrafine particles (UFP) or source-resolved PM<sub>2.5</sub>. Methods: We deployed an aerosol mass spectrometer (AMS) in a mobile laboratory and measured UFP concurrently in the mobile laboratory and with a network of fixed samplers. AMS provides real-time measurement of PM composition between organic and inorganic fractions, as well as full aerosol mass spectra of organic PM. Factor analysis of organic aerosol mass spectra allows for quantification of the contributions of both fresh emissions (e.g., traffic and cooking emissions) and aged secondary PM. Results: Variations in PM exposure are largely driven by proximity to fresh emissions sources, including traffic and cooking, with the relative importance of these sources varying with land use patterns. Average population weighted exposures to total traffic PM, the sum of contributions from organic aerosol and black carbon, was approximately 1  $\mu\text{g m}^{-3}$  above the regional background, with higher concentrations in high-traffic areas. Population-weighted exposures to cooking PM, which is almost entirely composed of organic aerosol, was approximately 0.5  $\mu\text{g m}^{-3}$ . Concentrations vary temporally, with higher traffic contributions in the morning and cooking dominating at midday and evening. Conclusions: Fresh emissions from cooking and traffic drive spatial variations in PM concentration in urban areas. Traffic remains the largest contributor to fresh PM emissions, though cooking emissions are also important. For organic PM, cooking is a larger source than traffic.

### **S02.03.09. A Dense Sensor Network to Characterize Community Exposure to Black Carbon**

Chelsea Preble

*Chelsea V. Preble<sup>1</sup>, Julien Caubel<sup>1</sup>, Troy Cados<sup>1</sup>, Joshua S. Apte<sup>2</sup>, Thomas W. Kirchstetter<sup>1</sup>*

*1. University of California, Berkeley, Berkeley, CA, United States.*

*2. University of Texas at Austin, Austin, TX, United States.*

**Abstract:** We developed a low-cost black carbon (BC) sensor and deployed over 100 of them as a connected air quality network in West Oakland, California. The West Oakland residential community is adjacent to port and rail facilities and surrounded by major freeways. As such, the community is affected by diesel particulate matter emissions from heavy-duty diesel trucks, locomotives, and ships associated with freight movement. In partnership with community stakeholders, we positioned BC sensors outside of residences and businesses, along truck routes and arterial streets, along the Port of Oakland boundary, and at upwind locations. We operated this first-of-its kind BC air quality network for 100 days in summer 2017 in conjunction with a complementary study of on-road air pollution mapping. Spatiotemporal patterns in BC concentrations in West Oakland are observed to be driven by truck activity within the community. Highest concentrations exist along truck routes, near trucking facilities, and around businesses that use trucks to transport goods and materials. Almost everywhere, BC concentrations are higher on week-days than weekend-days, as is truck activity. The community-average BC concentration matches well the concentration measured at a centrally located site operated by the Bay Area Air Quality Management District. However, on average, 75% of locations within the community are more polluted than the central monitoring site, with daytime average BC up to 1.75× higher. Daytime average BC concentrations along the Port of Oakland boundary and designated truck routes around the community are up to 3× higher than the central monitoring site average. Overnight, the spatial gradient within the West Oakland neighborhood diminishes, such that BC concentrations are more uniform. Areas downwind of the freeway, along the Port of Oakland boundary, and at some trucking facilities have persistent elevated BC concentrations in the evening and early morning hours.

### **S02.03.10. Mapping Air Pollution with Google Street View Cars: Towards Efficient Mobile Monitoring**

Kyle Messier

*Kyle Messier<sup>1</sup>, Sarah Chambliss<sup>1</sup>, Ananya Roy<sup>2</sup>, Julian Marshall<sup>3</sup>, Michael Brauer<sup>4</sup>, Adam Szpiro<sup>3</sup>, Chris Portier<sup>2</sup>, Jules Kerckhoffs<sup>5</sup>, Roel Vermeulen<sup>5</sup>, Joshua S. Apte<sup>1</sup>*

**Abstract:** Air pollution measurements collected through systematic mobile monitoring campaigns can provide exposure data at high spatial resolution. Approaches to minimize the amount of data and driving effort required to successfully map an urban area's air quality may help improve the scalability of this measurement approach. We explore the data requirements for mapping a city's air quality using mobile monitors utilizing "data only" and predictive model approaches. We used two Google Street View cars with fast-response (1 Hz) instruments to collect nitric oxide (NO) and black carbon (BC) measurements in Oakland, CA. This rich dataset incorporates ~ 3.6 million measurements collected repeatedly (20-50 ×) on every city street over 2 y. We explore two alternative strategies to efficiently mapping spatial air quality patterns. First, we use a "data-only" approach where we attempt to minimize the number of repeated visits to each road. Second, we combine our data with a land use regression-kriging (LURK) model to predict at unobserved locations, and consider sampling schemes where only a subset of a city's roads or repeat visits are measured. In all cases, we use a Monte Carlo scheme to systematically subsample the full dataset. LURK models consistently captured general spatial trends in urban air pollution, with cross-validation R<sup>2</sup> for log-transformed-NO and BC of 0.65 and 0.5. While LURK models did not capture the full variability of on-road concentrations, models could successfully be trained with minimal data requirements, e.g., with only a small number of repeated observations on ~20% of the roads. Data-only mapping performed poorly for < 4 repeated drives per road segment, but obtained surpassed the performance of LURK approach within 4 to 8 repeated drive days per road segment. Data-only mapping can have surprisingly modest data requirements. LURK models can efficiently produce valid predictions of air quality when it is not possible to sample air quality on every road.

### **S02.03.11. Use of Low-Cost Air Pollution Sensors in the Adult Changes in Thought Air Pollution Study**

*3. Biostatistics, University of Washington, Seattle, WA, United States.*

*4. Civil + Environmental Engineering & Environmental + Occupational Health Sciences, University of Washington, Seattle, WA, United States.*

Abstract: Incorporating modern air pollution sensor technology into epidemiologic cohort studies is appealing because of its low cost, allowing much better spatial representation of pollution exposure. Exposure sampling design can also leverage emerging understanding from measurement error correction methods that the monitoring network design should be spatially compatible with the locations where the health study participants live. However, research has not yet been conducted to determine whether these low-cost sensor data are reliable, accurate, and consistent enough to use for epidemiological study exposure assessment. Our scientific goal is to estimate individual-level long-term average exposures to PM<sub>2.5</sub> and oxides of nitrogen for inference about the effects of air pollution on brain health. To accomplish this we are developing new spatio-temporal pollution predictions based on recently collected low-cost sensor data combined with existing ambient monitoring data. I will discuss the necessary quality control criteria for using the low-cost sensor data in a spatio-temporal prediction model, including calibration of these measurements to federal reference measurements. I will present the improvement in the performance of the spatio-temporal predictions from adding the low-cost sensor data and discuss the implications of these results for improving inference from epidemiologic cohort studies such as the Adult Changes in Thought Air Pollution study.

**S02.03.13. Oil Extraction in the Coastal Basin of the Democratic Republic of the Congo: A Pilot Study**

Benoit Nemery

*Benoit Nemery<sup>1</sup>, Célestin Banza Lubaba Nkulu<sup>2</sup>*

*1. Public Health and Primary Care, KU Leuven, Leuven, Belgium.*

*2. Ecole de Santé Publique, Université de Lubumbashi, Lubumbashi, Congo (the Democratic Republic of the).*

Abstract: Following concerns, voiced by the local population and NGOs, about the consequences of the on-shore oil extraction along the Atlantic Ocean north of the Congo River estuary, the health authorities of the DR Congo requested a multidisciplinary team to conduct a pilot study to evaluate the possible environmental and human health impact of this activity. The field study was conducted during the last week of December 2015 (rainy season) by a team of experts in environmental health, toxicology and biology, with help from local health workers. Environmental samples (soil, air, water, fish) were collected in relevant locations close to or within oil extraction fields, as well as in a control area. Spot samples of urine were also obtained from 34 adults and 19 children living at various distances from oil extraction sites (convenience sampling). Concentrations of hydrocarbons (or their metabolites) and metals were later measured in the environmental and urine samples. This limited study did not find evidence of major environmental degradation or high human exposure to toxic agents in relation to on-shore oil extraction in the studied area. These findings do not imply that oil extraction can be done anywhere without risks for the environment or human health.

## **S02.03.14. Oil Extraction in the Amazon Basin and Levels of Metals among Indigenous Populations**

**Abstract:** Between May and August 2016 the Peruvian Ministry of Health conducted a cross-sectional study to assess levels of exposure to metals in the local population and establish risk factors in Corrientes, Pastaza, Marañón and Tigre river basins (Peru). 1168 people from 39 indigenous communities participated in the study. Information on socio-demographic variables and environmental exposures was collected in questionnaires. Blood and urine samples were collected from each study participant, and environmental samples were collected from each community to measure levels of metals and hydrocarbons. We used atomic absorption spectrophotometry to measure metals concentrations (Pb, As, Ba, Cd and Hg) in biological and environmental samples. We used multilevel mixed-effects linear regression models with a random effect for community and river basin, adjusted for potential confounders to study the association between socio-demographic variables and environmental exposures and levels of metals in biological samples. We used linear regression models to study the association between median concentration of metals on environmental samples and on biological samples at the community level. 57% of the study population had blood lead levels above 5 µg/dL and 28%, 13%, 9% and 26% of the study population had urinary levels of As, Ba, Cd and Hg, respectively, higher than those recommended by the Peruvian Ministry of Health (20 µg Cd/g As, 6 µg Ba/g creatinine, 2 µg Cd/g creatinine and 5 µg Hg/g creatinine). There were differences in levels of metals in environmental samples according to river basin. Inhabitants of communities with higher levels of Cd in agricultural soil presented higher levels Cd urinary levels than inhabitants from other communities. The analysis of risk factors at the individual level did not yield clear results. Differences in level of exposure to metals were generally explained by ethnic group, which might reflect geographical differences in levels of exposure.

### **S02.03.15. Cultural Strength, Connection to Land, Social Justice and the Adani Carmichael Mine: Placing Aboriginal Health and Wellbeing Front and Centre in Mining Decisions in Australia**

Melissa Haswell

*2. Indigenous Health Discipline, Graduate School of Health, University of Technology Sydney, Sydney, NSW, Australia.*

Abstract: The harvesting of Australia's massive mineral reserves began the 1840's; 50 years after Captain Cook landed in Botany Bay, driving massive population influx, environmental degradation and forced evacuation of Aboriginal homelands and communities. Today, the impacts of fossil fuel mining continue to disturb the physical, social and emotional, spiritual and cultural wellbeing and community cohesion of Aboriginal Australians. These First Australians already experience enormous inequalities in health, social and economic status, as well as transgenerational trauma from widespread death, systematic removal from Lands and disempowerment of family and culture since 1788. Today's Australian focal point of environmental activism is opposition to the \$16.5 billion Adani Carmichael mega-mine proposal to extract 6.3 billion tons of coal over 60 years from the Traditional Lands of the Wangan and Jagalingou people. Highlighting contravention of the UN Declaration on the Rights of Indigenous Peoples endorsed by Australia in 2009, Traditional Owner Adrian Burragabba warns, they will stop our dreaming. where will the song go; what will the song be; there will be nothing left. [but] we are still here and no still means no. Now is the time to stand stronger than ever to step up to the fight. Like most Indigenous Peoples, Aboriginal Australians recognise inseparable connections between the health of Land and its people. This talk examines benefits to epidemiologists in understanding the importance of social, emotional and spiritual wellbeing as a foundational environmental health determinant. We focus on principles developed by Aboriginal Australians (NHMRC Roadmap) to ensure that research strengthens health, spirit and integrity. We argue that these must underpin urgently needed research partnerships to improve health impact assessment with Aboriginal people facing destruction of their Lands and enforce deeper consideration in government decisions on fossil fuel developments.

## **S02.03.16. Documenting Complex Air Pollution Mixtures and Baseline Health Conditions in Fort McKay, Alberta**

Abstract: Environmental pollution from the oil sands industry in northern Alberta, Canada, is an ongoing concern. Fort McKay is an Indigenous community in close proximity to these sources. To improve understanding of the impacts of the air emissions on the environment and the community, detailed air monitoring was initiated by Environment and Climate Change Canada in 2013. Subsequent to this, but independent from it, Fort McKay joined a national Indigenous cohort which is sub-study of the Canadian Alliance for Health Hearts and Minds (CAHHM). In total 104 participants aged 18 to 69 years residing in Fort McKay were recruited, providing individual information via multiple questionnaires (medical history, risk factors, diet, physical activity), and via physical and cognitive measures and blood samples (hemoglobin A1C and Apolipoproteins). Consistent with the CAHHM national protocol, a majority (N=87) of the Fort McKay participants underwent Magnetic Resonance Imaging (brain, heart, carotid and abdomen), consented to follow-up via health record linkage and to blood storage for possible genetic research with further consent. Community-level environmental contextual factors were also assessed. Establishing this strong baseline of health data and community engagement within the broader context of a national study is expected to enable research on a range of health questions geared towards a better understanding of why Indigenous people have higher rates of death from CVD compared to the Canadian population, and how, through community-based approaches, this burden can be reduced. Potential health impacts of long-term air pollutant exposures can also be explored given the national CAHHM platform. The purpose of this presentation will be to provide an overview of this work to date, including community air pollutant exposures, challenges and opportunities.

## **S02.03.17. Tar Sands Operations and Waterborne Exposure and Subsistence Food Supply in Canada**

Eriel Deranger

*Eriel Deranger<sup>1</sup>*

### *1. Indigenous Climate Action, Edmonton, AB, Canada.*

Abstract: The political divide surrounding the development of the Alberta oil sands has created escalating tensions between political leaders, Canadian citizens and Indigenous communities alike. Indigenous communities at the centre of this debate cite historical denial of inherent, Treaty and international rights, via exclusion from permitting, development and regulation of the oil sands. To date Alberta oil sands have contributed to the disturbance of over 500 km<sup>2</sup> of boreal and peatlands in the Athabasca River watershed, contributing to the irreversible transformation and contamination of traditional lands and water systems. There is increasing evidence of polycyclic aromatic hydrocarbons and other toxicants entering water systems and contaminating food systems (ie. fish, migratory birds, small and large mammals). Continued expansion of Alberta oil sands undermines Indigenous rights to protect land, food, water and medicines and raises concern of multi-generational impacts (environmental, health, socio-economic, and Indigenous rights). The presentation will explore western science and Indigenous science studies highlighting downstream Indigenous communities concerns of contamination of critical water systems created via Alberta's oil sands; how recognition of Indigenous rights are essential to policy and regulation of the industry; and overall impacts of extractive industries on local Indigenous people efforts to implement international rights standards under UNDRIP (ie. Free, Prior and Informed Consent).

### **S02.03.18. Environmental Injustice: Local (Environmental Contamination) and Global (Climate Change) Effects from the Use of Fossil Fuels on Those Who Benefit Least from Their Use**

Adetoun Mustapha

*Adetoun Mustapha<sup>1</sup>, Colin L. Soskolne<sup>2</sup>*

*1. Epidemiology and Biostatistics, MRC-HPA Centre for Environment and Health , Imperial College London, Lagos, Nigeria.*

*2. University of Alberta, Montreal, AB, Canada.*

Abstract: Continuing carbon emissions and the associated consequent rise of mean global temperatures from the combustion of fossil fuels has had and will continue to have profoundly worsening implications in resource-constrained regions of the world. Most communities in industrializing/developing parts of the world live in climate-sensitive locations and most economies in such regions depend on natural resources. Ongoing degradation of natural resources from human activities and reduced agricultural productivity are worsening with climate change and will continue to make these regions uninhabitable, affecting poverty trajectories and migration patterns on a massive scale. This discussion reviews environmental episodes among indigenous peoples, their ethical dimensions, and identifies mitigation strategies to protect these vulnerable communities. Although growth in gross domestic product in theory is supposed to result in a rise in population standards, in practice, with the ever widening gulf between rich and poor, the net-negative effects fall on those who benefit least from the continued use of fossil fuels. A paradigmatic shift is needed, especially focused on respect for local community sustainability.

S02.03D. The European Human Biomonitoring Initiative HBM4EU: Harmonizing Exposure and Health Risk Assessment in Europe to Support Science and Policy  
**S02.03.19. Integrated Exposure Modeling for Human Biomonitoring Data Assimilation**

Dimosthenis Sarigiannis

*Dimosthenis A. Sarigiannis<sup>1</sup>, Spyros Karakitsios<sup>1</sup>*

*1. Chemical Engineering, Aristotle University of Thessaloniki, Thessaloniki, Greece.*

**Abstract:** The integrated exposure assessment framework in HBM4EU aims at introducing a comprehensive methodological approach which will be implemented in a computational platform. The aim is to assess the source-to-dose continuum of a large space of chemical substances, towards the effective assimilation of human biomonitoring (HBM) data. The platform will integrate environmental fate, exposure and internal dose dynamically in time and across different spatial resolutions (from local to global). This description requires the use of multimedia environmental and micro-environmental modelling, exposure analysis incorporating multiple pathways and routes of exposure, and Physiology Based Toxicokinetic (PBTK) modelling. Exposure analysis up to internal dose, will allow the interpretation of actual dosimetry to target tissues to in vitro assay results. This is of particular importance for the precise estimation of doses that relate to molecular perturbations within adverse outcome pathways (AOPs). Biomonitoring data interpretation is another challenge of the methodology, described as the "reverse modeling" calculations for exposure reconstruction. Following this, and based on the amount and quality of prior information, quantitative predictions, ranging from the overall exposure burden up to pathway/route specific information could be made; this will provide a very comprehensive instrument for policy makers, that will allow them to point out the cost-efficient interventions (which sources contribute mostly to exposure), directly from HBM data. The applicability of the methodology has been demonstrated in the case of bisphenol-A, Exposure reconstruction of available HBM data resulted in very low intake estimates, while the use of in vitro data regarding its estrogenic activity, indicated that there is no reason for concern for individual or aggregate scenarios of BPA exposure in the EU population.

## **S02.03.20. Complementary Strategies for Suspect and Untargeted Screening of Emerging Substances in Human Matrices**

Jean-Philippe Antignac

*Jean-Philippe Antignac<sup>1</sup>, Ronan Cariou<sup>1</sup>, Alexis Leon<sup>1</sup>, Sébastien Hutinet<sup>1</sup>, Mariane Pouchet-Gellez<sup>1</sup>, Yann Guitton<sup>1</sup>, Bruno Le Bizec<sup>1</sup>*

*1. UMR 1329 LABERCA, Oniris-INRA, Nantes, France.*

**Abstract:** The emerging chemicals challenge clearly appears as a major current concern for the scientific community, societal actors, and public authorities. However, this issue still remains imperfectly defined and may cover different aspects both from a conceptual and methodological point of view. In the scope of the HBM4EU project and its related WP16, emerging chemicals should be understood as chemicals of emerging concern. These emerging substances are not yet included in existing HBM programs, mainly due to the absence of analytical methods available to determine the considered chemical or its metabolites in human specimens. For this reason, new approaches permitting to analyse these compounds in the broadest way are mandatory. Current mass spectrometric instrumentation, especially high resolution devices, offers a great opportunity to develop such extended suspect or untargeted screening methods from various human biological material. In addition to these chemistry driven approaches, Effect-Directed Analysis (EDA) approaches can be also useful for performing a biological activity driven screening. All together, these approaches aim to address the complex question of emerging substances using complementary angles respectively based on exposure assessment and hazard characterization. Finally, their combination is expected to contribute to risk assessment and support to policy by providing data related both to the reality of human exposure and to the potential toxicity of the considered substances. All these different approaches for untargeted screening will be developed and applied within the HBM4EU WP16.

### **S02.03.21. HBM4EU Mixtures, Human Biomonitoring and Human Health Risk: Methods to Describe Mixture Exposures in the European Population Based on Human Biomonitoring Data**

Erik Lebret

- 2. IRAS-UU, Utrecht, Netherlands.*
- 3. RIVM, Bilthoven, Netherlands.*

Abstract: Humans are exposed to a myriad of concurrent and protracted environmental, occupational, dietary, lifestyle and consumer product exposures. These mixtures of exposure can form an almost infinite number of different combinations of chemicals, which makes the risk assessment extremely challenging. The term mixture (in the context of human biomonitoring) is used to describe any combination of exposure of internal dose biomarkers that has been measured in one or more biological matrices of a person during a single time point. These biomarkers include the chemical substances themselves, as well as their metabolites. The mixture might include compounds from multiple substances groups, but also from multiple compounds from the same substance group. One of our main research questions is "What patterns can we observe amongst body burdens of different substances within individuals, and can we identify hotspots or risk groups with high body burdens of mixtures and/or high mixture risks?" Understanding the correlation patterns, latent structures and functional networks of these mixtures of exposure could provide information on the occurrence of mixtures, common sources and routes of exposure. Such occurrence information is pivotal in mixture risk assessment. Distributions of (patterns) in biomarker mixtures across Europe will be described based on available human biomonitoring datasets. These distributions can be stratified by determinants such as country, region, sampling period, personal characteristics, etc. Using network visualization tools and differential network analyses, we explored similarities and differences in network structures in available human biomonitoring datasets. During this presentation the methods of the network visualization and differential network analysis will be presented.

## **S02.03.22. Communication in HBM4EU and Sustainability Post 2021**

Catherine Ganzleben

*Catherine Ganzleben<sup>1</sup>*

*1. European Environment Agency, Copenhagen, Denmark.*

Abstract: The presentation will describe the strategy for the communication and dissemination of HBM4EU results. Effective and targeted dissemination of HBM4EU outputs is crucial to ensuring that key audiences both understand and use our results for the protection of human health. Our target audiences include policy makers, the scientific community, NGOs, industrial representatives, trade unions and members of the public, with each having distinct demands for knowledge on chemical exposure. In particular, the effective communication of results to risk assessors and risk manager via tailored communicated products is essential to building a bridge between science and policy. The long-term aim of developing the architecture and securing the funding and political will for a sustainable human biomonitoring initiative in Europe will also be addressed.

### **S02.03.23. HBM in Human Risk Assessment and Health Impact Assessment: Translation of Results into Policy**

Jos Bessems

*Jos Bessems<sup>1</sup>, Greet Schoeters<sup>1</sup>, Tiina Santonen<sup>2</sup>*

*1. VITO (Flemish Institute for Technological Research), Mol, Flanders, Belgium.*

*2. FIOH (Finnish Institute of Occupational Health), Helsinki, Finland.*

Abstract: This presentation will focus on major activities in HBM4EU Work Package 5 'Translation of results into policy'. Starting point is a number of limitations with respect to the HBM (human biomonitoring) instrumentation but also in knowledge and acceptance of HBM in human risk assessment (HRA) and human health impact assessment (HIA). So there are quite some challenges related to it. Following a wide survey in the EU, needs were identified for the better inclusion of HBM in HRA and HIA practices. A first clear need are health-based HBM guidance values as indicative internal limit values, necessary to use exposure biomarker results in preliminary risk assessments. A second need is better regulatory incorporation (clearer legislative role) of HBM but also guidance on the 'when' and 'how' and the 'pros', 'cons' as well as caveats that go with the use of HBM in HRA and HIA. A third one is better communication with risk managers and policy makers, a topic for which easy understandable HBM-based indicators are being established. A last one is a stepwise approach on how to involve stakeholders in the scientific, policy and societal (citizens) arena in order to reach awareness, acceptance and generation of HBM data but also science- and participatory-approach based chemical policy recommendations.

## **S02.03.24. HBM4EU: The European Human Biomonitoring Initiative**

Marike Kolossa-Gehring

*Marike Kolossa-Gehring<sup>1</sup>, Ulrike Doyle<sup>1</sup>, Rosa Lange<sup>1</sup>, Kim Pack<sup>1</sup>, Lena Reiber<sup>1</sup>*

*1. German Environment Agency (UBA), Berlin, Germany.*

Abstract: HBM4EU follows an innovative approach to generate the knowledge policy makers need to improve policy in the field of environment and health. The overarching goal of HBM4EU is to generate new knowledge, to inform the safe management of chemicals, and consequently protect human health in Europe. Human Biomonitoring data supply information on the aggregated internal exposure from all sources and by all pathways. They will serve as the basis to assess the risks from human exposure to chemicals. Intensive communication and involvement with policy makers ensures that HBM4EU results are used in the further development and design of new chemicals policies and in the evaluation of existing measures. HBM4EU consists of 109 partner organisations from 28 countries - 27 European countries and Israel - and is organised around 16 work packages led by key players of national HBM studies and research programmes. It builds upon existing knowledge from national and EU monitoring and research programmes. Major fields of activities are the science to policy transfer, harmonisation of HBM studies, and research to elucidate the impact of exposure on health. HBM data are currently fragmented in Europe. Exposure data valid for the whole of Europe, the identification of vulnerable or highly exposed subpopulations and the analysis of spatial and temporal exposure trends are major goals of HBM4EU. HBM reveals the extent and quality of multiple chemicals exposures and demonstrates the need to develop concepts for health risk assessment beyond traditional single substance evaluation methods. The research program of the European Joint Project is based on the policy needs and priority chemicals identified after consultation with European and national policy makers. This project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 733032.

Abstract: The HBM4EU initiative is aiming to coordinate and advance human biomonitoring (HBM) in Europe. It will provide better knowledge of the actual exposure of citizens to chemicals, to support policy making. The initiative is a joint effort of 28 countries, of 109 partner organisations, co-funded under Horizon 2020 and will run from 2017 to 2021, building on previous activities undertaken at EU and national levels. HBM4EU will contribute to fill the data gaps for the exposure to prioritized chemicals, through chemical analysis of human samples in a harmonized way. Thus, a specific work package is dedicated to Laboratory analysis and quality assurance (QA). Specific tasks include the inventory and selection of best-suited biomarkers and matrices for the prioritized substance groups (three rounds of prioritization of chemical groups are planned along the project). The establishment of networks of HBM laboratories for biomarker analysis and support of the QA program at EU level, as well as for developing new methods on identified gaps. A Quality Assurance Unit (QAU) with experts in HBM chemical analysis has been established to assess the process and secure comparability of HBM4EU results. We have developed Standard Operating Procedures for guiding main aspects in the harmonization process of EU laboratories. An ambitious program for intercomparison laboratory exercises (ICI/EQUAS) has been designed with a total of 76 individual human biomarkers for the first round of priority substance groups (phthalates, flame retardants, poly- and perfluoroalkyl substances, polycyclic aromatic hydrocarbons, bisphenols, anilines, cadmium and, chromium). Candidate laboratories need to participate in at least three proficiency rounds and successful results in the ICI/EQUAS program is required for European labs to analyze HBM4EU samples. This project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 733032.

## **S02.03.26. A Framework for the Collection of HBM Data in Europe to Study Spatial and Time Trends of Chemical Exposure in European Citizens**

Greet Schoeters

*Greet Schoeters<sup>1</sup>, Liese Gilles<sup>1</sup>, Eva Govarts<sup>1</sup>, Gudrun Koppen<sup>1</sup>, Sylvie Remy<sup>1</sup>, Loïc Rambaud<sup>2</sup>, André Conrad<sup>3</sup>, Nina Vogel<sup>3</sup>, Ovnair Sepai<sup>4</sup>, Argelia Castaño<sup>5</sup>*

2. Santé Publique France, Paris, France.
3. UBA, Berlin, Germany.
4. Public Health England, London, United Kingdom.
5. Instituto de Salud Carlos III, Madrid, Spain.

Abstract: The European Joint Programme HBM4EU is the backbone for knowledge on human exposure to environmental chemicals in the EU. It will inform European and national policy makers to take science based decisions for reducing chemical exposure of EU citizens to hazardous compounds. To answer policy questions on current EU-wide exposure to a selection of 8 priority substance groups, we have developed a framework for sampling which is based on existing and planned studies. The aim is to collect human biomonitoring data that will be comparable and hence allow to calculate reference values for Europe, to get information on the regional distribution of the priority chemicals in European citizens, and to evaluate the efficacy of EU and national policies. Current exposure is defined as exposure measured in samples collected between 2014 and 2019. To obtain comparable data from existing national and regional studies of 20 countries fieldwork and sampling protocols were developed to facilitate harmonisation. Biomarker analysis will be quality assured. As the importance and effective prevention of early life exposures is widely recognised, we focus in a first phase of HBM4EU on prepuberty, puberty and reproductive age groups. As such children between 6 and 11 years, teenagers between 12 and 19 years old and young adults between 20 and 39 years of age will be included in the first survey. Data will be collected and shared through the data platform IPCHEM, hosted at the EC Joint Research Centre (Ispra, IT). The survey will be an important step towards a sustainable HBM framework in the EU. At the same time biomolecular and advanced exposure modelling research will be grafted on this framework to better understand risks and health impact of exposure to environmental chemicals in Europe.

## O02.04A. Air Pollution, Pregnancy and Perinatal Health Outcomes

### O02.04.01. Time-Varying Exposure to Fine Particulate Matter and Black Carbon and Outcomes of In Vitro Fertilization

Audrey Gaskins

*Audrey J. Gaskins<sup>1</sup>, Kelvin C. Fong<sup>1</sup>, Yara Abu Awad<sup>1</sup>, Lidia Minguez-Alarcón<sup>1</sup>, Jorge E. Chavarro<sup>1</sup>, Brent Coull<sup>1</sup>, Joel D. Schwartz<sup>1</sup>, Russ Hauser<sup>1</sup>, Francine Laden<sup>1</sup>*

*1. Harvard T.H. Chan School of Public Health, Boston, MA, United States.*

**Abstract: Background/Aim:** Air pollution has been linked to decreased fertility yet the specific mechanisms and windows of susceptibility remain unclear. We examined the association between time-varying exposure to fine particulate matter (PM<sub>2.5</sub>) and black carbon (BC) on in vitro fertilization (IVF) outcomes. **Methods:** We included 356 women (537 cycles) for the PM<sub>2.5</sub> analysis (2005-2016) and 234 women (343 cycles) for the BC analysis (2005-2011) enrolled in a prospective cohort study of couples undergoing a fresh IVF cycle in New England. We used spatiotemporal models to estimate daily PM<sub>2.5</sub> and BC exposures (based on residential address) throughout the IVF cycle. Multivariable discrete time Cox proportional hazards models with 3 time periods (cycle initiation to embryo transfer (ET), ET to implantation, implantation to live birth) were used to estimate odds ratios (OR) and 95% confidence intervals (CI) of failing at IVF. Time-dependent interactions between exposures and IVF time windows were used to identify vulnerable periods. **Results:** An interquartile range (IQR) increase in PM<sub>2.5</sub> (3 µg/m<sup>3</sup>) and BC (0.2 µg/m<sup>3</sup>) throughout the IVF cycle was associated with a non-significant, elevated odds of failing at IVF prior to live birth (OR=1.15, 95% CI 0.96, 1.38 for PM<sub>2.5</sub> and OR=1.25, 95% CI 0.87, 1.78 for BC). The effect of PM<sub>2.5</sub> and BC exposure on IVF failure was strongest during the earliest windows of IVF. Specifically, an IQR increase in PM<sub>2.5</sub> and BC exposure was associated with 1.30 (95% CI 1.01, 1.67) and 1.55 (95% CI 1.15, 2.10) times the odds of failing prior to ET, 1.07 (95% CI 0.82, 1.39) and 1.18 (0.77, 1.80) times the odds of failing between ET and implantation, and 1.05 (0.59, 1.88) and 0.82 (0.43, 1.59) times the odds of failing between implantation and live birth. **Conclusion:** Increased exposure to PM<sub>2.5</sub> and BC during ovarian stimulation is associated with higher odds of IVF failure prior to ET. Acute exposure to PM<sub>2.5</sub> and BC may have adverse effects on oocyte development.

## **002.04.02. Air Pollution and Preterm Birth: Do Air Pollution Changes over Time Influence Risk in Consecutive Pregnancies among Low-Risk Nulliparous Women?**

Pauline Mendola

*Pauline Mendola<sup>1</sup>, Carrie Nobles<sup>1</sup>, Andrew Williams<sup>1</sup>, Danping Liu<sup>3</sup>, Seth Sherman<sup>2</sup>, Indulaxmi Seeni<sup>1</sup>, Katherine Grantz<sup>1</sup>*

*1. Division of Intramural Population Health, NIH/NICHD, Bethesda, MD, United States.*

*2. Emmes Corporation, Rockville, MD, United States.*

*3. NIH/National Cancer Institute, Shady Grove, MD, United States.*

Abstract: Both air pollution, generally decreasing in the U.S., and having a prior preterm birth (PTB) are risk factors for subsequent pregnancy PTB. To investigate whether air pollution exposures would have a potential differential effect on PTB risk in the first and second pregnancy among low-risk women, we estimated exposures based on modified Community Multiscale Air Quality models linked to the NICHD Consecutive Pregnancy Study. Electronic medical records for consecutive delivery admissions were available for 27,137 nulliparous women with singleton births in 20 Utah-based hospitals between 2002-10. We categorized whole pregnancy exposures based on percentiles as high (>75), moderate (25-75) and low (<25). Modified Poisson regression with generalized estimating equations estimated PTB risk in the second pregnancy associated with persistent high and moderate exposure, and increasing or decreasing exposure, compared to persistent low exposure. Analyses were adjusted for prior PTB, interpregnancy interval and other demographic and clinical characteristics. Pollution levels generally decreased over time, reducing the number of women with high second pregnancy exposure. Second pregnancy PTB risk was increased when exposure increased for sulfur dioxide (34%), ozone (80%), nitrogen dioxides (NO<sub>2</sub>; 38%), and carbon monoxide (CO; 33%) versus stayed consistently low. Similar trends were observed for consistently high versus consistently low exposure. We also observed significant interaction by prior PTB status. Women with no prior PTB had significantly higher risk associated with increasing levels of several pollutants as compared to women with prior PTB, including NO<sub>2</sub> (increase of 63% vs. decrease of 7%, p-interaction=0.004) and CO (increase of 57% vs. no change, p-interaction=0.031). These findings suggest area-level changes in air pollution exposure have important consequences in repeated pregnancies even among low risk women at moderate levels of exposure in the U.S.

### **002.04.03. Prenatal Exposure to CO and NO<sub>2</sub> and Reduced Term Birthweight: A Pilot Study Utilizing Hospital-Based Delivery Data for Environmental Health Research in New Delhi, India**

Shakoor Hajat

*Melina S. Magsumbol<sup>1</sup>, Arpita Ghosh<sup>2</sup>, Archana Singh<sup>3</sup>, Neelam Kler<sup>4</sup>, Atul Srivastava<sup>5</sup>, Anup Thakur<sup>4</sup>, Pankaj Garg<sup>4</sup>, Indrani Ganguli<sup>6</sup>, Shakoor Hajat<sup>7</sup>*

- 7. Social and Environmental Health Research, London School of Hygiene and Tropical Medicine, London, United Kingdom.*

**Abstract:** Background New Delhi is one of the most polluted cities in the world. Pregnant women are exposed to criterion air pollutants that are suspected to reduce birthweight. This study investigates the association of CO and NO<sub>2</sub> exposure to birthweight of term neonates born in New Delhi from 2007-2012 (N=10,565) using hospital-based data linked with 10 continuous air quality monitoring station (CAQMS) data reported by the Central Pollution Control Board. Due to the absence of a national birth registry in India, it is important to utilize existing hospital datasets for environmental health assessment studies. Methods 2007-2012 average levels of carbon monoxide (CO), and nitrogen dioxide (NO<sub>2</sub>) were obtained and linked to delivery data during the same timeframe in an urban hospital in New Delhi. Data from stations within 10 kilometres of maternal residence were assigned to each birth record. Multiple regression analysis was conducted to detect associations between levels of exposure to pollutants and term low birth weight. Results An interquartile range (IQR) increase in ambient pollutant concentrations of CO (580 ppb) and NO<sub>2</sub> (26 ppb) during the whole pregnancy was associated with a 19g (95% CI: -36, 2) and 18g (95% CI: -33, -3) decrease in birth weight, respectively, for all births. We assessed pollutant effects by trimester to identify biological exposure window of concern. For CO, the effect is most pronounced during the first trimester. An IQR increase in CO and NO<sub>2</sub> was associated with a 26g (95% CI: -50, -3) and 27g (95% CI: -48, -6) decrease in birth weight, respectively, in female births; results were not significant for male births. Conclusions Pregnant women and their neonates are exposed to high levels of CO and NO<sub>2</sub> in New Delhi. The medical community can contribute to the policy dialogue by utilizing hospital data for environmental health research. There is a need for a national birth registry to assess early exposures to pollutants and life course impact.

#### **O02.04.04. Maternal Exposure to Outdoor Air Pollution and Congenital Limb Deficiencies in National Birth Defects Prevention Study**

**Abstract:** Background Congenital limb deficiencies (CLDs) are a relatively common phenotypic grouping of birth defects. Emerging evidence from recent studies suggests air pollutants as potential risk factors. Aim To investigate the relationship between ambient air pollution during early pregnancy and CLDs. Methods During 1997-2007, 595 cases of CLDs and 5,432 controls were identified from the National Birth Defects Prevention Study, a multi-center population-based case-control study. Weekly and overall averages of 6 criteria air pollutants (particulate matter <2.5µg/m<sup>3</sup> [PM<sub>2.5</sub>], PM<sub>10</sub>, nitrogen dioxide [NO<sub>2</sub>], sulfur dioxide [SO<sub>2</sub>], carbon monoxide [CO], and ozone [O<sub>3</sub>]) during gestational weeks 2-8 were estimated with EPA air monitors nearest to the maternal address recorded at birth. Logistic regression was used to estimate adjusted odds ratios (aORs) and 95% confidence intervals (CIs), considering potential confounders: maternal age, race/ethnicity, education, and study center. We additionally analyzed CLD subtypes (i.e., transverse, longitudinal, and intercalary), assessed modification by body mass index, cigarette smoking, folic acid use, and distance to air monitor, and adjusted for co-pollutants. Results We observed near-null adjusted associations between CLDs and PM<sub>10</sub>, PM<sub>2.5</sub>, and O<sub>3</sub>. However, weekly averages of the daily NO<sub>2</sub> and SO<sub>2</sub>, and daily maximum 1-hour CO concentrations were associated with increased odds of CLDs. The largest and most consistent effect was in CO (week 2 aOR: 1.13 per 1 ppm change, 95% CI: 1.00-1.27), with similar trends for CLD subtypes. The aORs for CO were elevated if mothers did not use folic acid or lived within 20km of an air monitor. The aORs for SO<sub>2</sub> were elevated if mothers were obese or were smokers. In co-pollutant models, CO was associated with elevated odds of CLDs (aORs: 1.02-1.30) and aORs for SO<sub>2</sub> and NO<sub>2</sub> were attenuated. Conclusion CO may be associated with CLDs, and further epidemiologic and mechanistic research is warranted. Disclaimer The views expressed in this abstract are those of the authors and do not necessarily represent the views or policies of the U.S. Environmental Protection Agency, the Centers for Disease Control and Prevention, or the California Department of Public Health.

## **O02.04.05. Increased Risk of Infant Mortality Associated with Pre and Postnatal Exposures to PM2.5 in South Korea: A Propensity Score-Matched Analysis**

Eun Mi Jung

*Eun Mi Jung<sup>2</sup>, Hae Soon Kim<sup>2</sup>, Hye Sook Park<sup>2</sup>, Seulbi Lee<sup>2</sup>, Hwashin H. Shin<sup>1</sup>, Eun-Hee Ha<sup>2</sup>*

- 1. Math & Stat, Queen's Univ., Kingston, ON, Canada.*
- 2. Medicine, Ewha Womans Univ, Seoul, Korea (the Republic of).*

**Abstract:** Background Evidence on the effect of pre and postnatal exposures to PM10 and PM2.5 on infant mortality is still scarce. We aimed to investigate exposures in six exposure periods (EPs) to explore the associations with infant mortality and their changes over time during pregnancy. **Methods** We used a 2010-15 retrospective birth cohort data obtained from Statistics Korea. We examined 5 cause-specific infant mortalities based on the ICD-10: sudden infant death syndrome (R95), circulatory (I00-99), respiratory (J00-99), perinatal conditions (P00-96), and congenital malformations (Q00-99). Out of 2,525,109 infants 1,530 deaths (0.06%) were identified. With propensity score matching stratified into quintile a 1:2 match was conducted, which was controlled for sex, gestational age, and city size (metropolitan/others). We calculated mean PM2.5 concentrations, using ground monitoring data and Community Multiscale Air Quality model for the following six EPs: each trimester (EP 1-3), gestational period (EP 4), postnatal period (EP 5), and whole period (EP 6; from conception to death). Models were adjusted for infant's address, maternal education level, maternal age, birth weight, and season of birth. A conditional logistic model was applied to take matching and stratification into account. **Results** Adjusted conditional logistic regression resulted in statistically significant associations between PM2.5 and infant death for all 6 EPs. A 1µg/m<sup>3</sup> elevation in PM2.5 concentrations was associated with 2% (95% CI, 1%-4%), 2% (1%-4%), 3% (2%-5%), 6% (4%-9%), 3% (2%-5%), and 15% (12%-19%) increase in infant mortality for ETs 1 to 6, respectively. **Conclusion** the study findings suggest that pre and postnatal exposures to PM2.5 could be a risk factor for infant mortality and that the association depends on the length of ET: The longer, the higher. Since the 5 causes were combined, further studies on each cause in relation with infant mortality are necessary as more data become available.

## O02.04B. Greenness Effects 1

### O02.04.06. Green Spaces and Cognitive Decline over 10 Years of Follow-Up in the Whitehall II Cohort

Cathryn Tonne

*Carmen de Keijzer<sup>1</sup>, Cathryn Tonne<sup>1</sup>, Xavier Basagaña<sup>1</sup>, Antonia Valentin<sup>1</sup>, Archana Singh-Manoux<sup>2</sup>, Jordi Alonso<sup>3</sup>, Josep M Antó<sup>1</sup>, Mark Nieuwenhuijsen<sup>1</sup>, Jordi Sunyer<sup>1</sup>, Payam Dadvand<sup>1</sup>*

*2. Centre for Research in Epidemiology and Population Health, INSERM, Paris, France.*

*3. Health Services Research Unit, IMIM, Barcelona, Spain.*

**Abstract:** Cognitive function is one of the most important indicators of healthy ageing. Evidence on beneficial associations of green space with cognitive function at older age is scarce and mainly limited to cross-sectional studies. This longitudinal study investigated the association between long-term green space exposure and cognitive decline. The analyses were based on three waves of data from the Whitehall II cohort, providing a 10-year follow-up of 6506 civil servants (45-68 years old) from the UK. Residential surrounding greenness was obtained across buffers of 500 and 1000 meter around the participants' residential address at each follow-up using satellite images on greenness (Normalized Difference Vegetation Index, NDVI) from a summer month in each follow-up period. Four cognitive tests were repeated three times over the study period, assessing reasoning, verbal fluency, and short-term memory. The cognitive scores were standardized and summarized in a "global cognition" z-score. To quantify the impact of greenness on the repeated measurements of cognition, linear mixed effect models were developed that included an interaction between age and the indicator of greenness, and controlled for covariates including individual and neighbourhood indicators of socioeconomic status. An interquartile range increase in NDVI was associated with a difference in the global cognition z-score of 0.020 (95% confidence interval (CI): 0.003 to 0.037) over 10 years. Comparing study participants of 55.7 years old, this difference was equivalent to a 4.6% slower decline over 10 years. Similar positive associations were also observed for the separate cognitive scores of reasoning (0.022, 95% CI: 0.007 to 0.038) and verbal fluency (0.021, 95% CI: 0.002 to 0.040), but not for short-term memory (-0.003, 95% CI: -0.029 to 0.022). The associations were stronger among women. To conclude, in this longitudinal study, higher residential surrounding greenness was associated with slower cognitive decline.

## **O02.04.07. Area-Level Urban Green Space and Suicide Mortality in Hong Kong**

William Goggins

*2. Department of Architecture, The Chinese University of Hong Kong , Shatin, Hong Kong.*

**Abstract:** Background: Previous studies have found positive associations between urban green space and better physical and mental health. In addition many ecological studies have found that greater residential area green space was associated with lower mortality rates, although some of these studies found no significant associations between green space and mortality. Methods: We obtained data on all suicide deaths in Hong Kong from 2008 through 2014 classified by 5-year age group, gender, and small area of residence. Mean normalized difference vegetation index (NDVI), and indicator of greenery, was estimated for all small areas for the year 2011 from a satellite image. Negative binomial regression with logarithm transformed suicide counts as the outcome and age group, gender, NDVI, and area-level socioeconomic indicators as predictors, with person-years as the offset term. Results: An increase in area level NDVI from the 25th to 75th percentile was non-significantly associated with a relative risk of suicide mortality = 0.91 (95% confidence interval = 0.81, 1.03) after controlling for age, gender, and small area level socioeconomic status variables. Lower area level education levels and higher percentage never married individuals, but not median household income, were significantly associated with higher suicide mortality rates. Conclusions: Higher area level green space may be associated with lower suicide mortality rates but further studies are needed to confirm this association.

## **O02.04.08. The Association between Medium- and High-Resolution Residential Greenspace Measures and Respiratory Health in Children from an Urban Environment**

J. Michael Wright

*J. Michael Wright<sup>1</sup>, Rebecca Gernes<sup>2</sup>, Cole Brokamp<sup>3</sup>, Glenn Rice<sup>1</sup>, Michelle Kondo<sup>5</sup>, Yvonne Michael<sup>6</sup>, Geoffrey Donovan<sup>5</sup>, Demetrios Gatzliolis<sup>5</sup>, David Bernstein<sup>3</sup>, Grace LeMasters<sup>3</sup>, James Lockey<sup>3</sup>, G. **Abstract:** Previous epidemiological studies of greenspace (GS) and respiratory health studies have not compared GS measures of varying resolution; nor have they examined lung function measures. We examined medium- and high-resolution residential GS measures and respiratory endpoints among 378 participants in the longitudinal Cincinnati Childhood Allergy and Air Pollution Study. We estimated residential GS exposure for participant addresses based on 400 meter (m) radial buffers using Normalized Differential Vegetation Index (NDVI) at a 30 m resolution and Urban Tree Canopy (UTC), including separate tree and grass coverage measures, at 1.5-2.5 m resolution. Associations between GS and asthma and lung function tests at age 7 were examined using linear and logistic regression adjusted for individual- and neighborhood-level confounders. We examined 100 and 800 m NDVI buffer sizes and a 6 months of age exposure window. Although not always statistically significant, we saw improved lung function per each 10% increase in overall UTC coverage. For example, a 4% increase was noted for forced expiratory flow at 25-75%, while 2% increases were seen for forced vital capacity and forced expiratory volume in the first second. Associations similar in magnitude were detected for NDVI. We also detected a decreased risk for asthma based on NDVI data for both 7 years (adjusted odds ratio (aOR)=0.82; 95%CI: 0.59-1.12) and 6 months of age (aOR=0.85; 95%CI=0.53-1.34). Few discernible patterns emerged across different buffer sizes for NDVI or UTC measures, although the strongest association with asthma was found for the 800m buffer at 6 months of age (aOR=0.60; 95%CI: 0.38-0.95). Although we saw little evidence of differences between medium- and high-resolution measures, GS was generally associated with improved childhood respiratory health. The views expressed in this abstract are those of the authors and do not necessarily reflect the views or policies of the U.S. Environmental Protection Agency.

## **002.04.09. Perceived Stress and Sleep Quality in an Urban Population: The Potential Role of Neighborhood Greenspace**

Lin Yang

*Lin Yang<sup>1</sup>, Janice Yuen-Shan Ho<sup>1</sup>, Ka Long Chan<sup>1</sup>, Katherine Ka Pik Chang<sup>1</sup>, Candy Lai Har Wu<sup>1</sup>, Derrick Ho<sup>1</sup>, Judy Siu<sup>1</sup>, Charles Wong<sup>1</sup>, Fiona Wong<sup>1</sup>, John Yuen<sup>1</sup>, Frances Wong<sup>1</sup>*

*1. The Hong Kong Polytechnic University, Hong Kong, Hong Kong.*

**Abstract:** Background: Greenspace has been associated with both perceived stress and sleep quality in the literature. However, few studies have investigated the potential modifying role of neighborhood greenspace on the adverse effect of perceived stress on sleep quality in urban residential populations. Methods: A face-to-face survey was conducted during May to August 2017. We successfully interviewed 614 Chinese adults aged 20 years or above who had lived in Hong Kong in past two years. They completed a 20-minute questionnaire with the items of Sleep Quality Index (SQI), Perceived Stress Scale (PSS), and International Physical Activity Questionnaires (IPAQ). Normalized Difference Vegetation Index (NDVI) near their residential addresses were extracted for each participant to represent the individual neighborhood greenspace coverage. Multinomial logistic regression models were applied to SQI (=1 as good sleep quality, 2-8 as moderate and 9-16 as poor). The variables that reached statistical significance ( $p < 0.05$ ) in univariate logistic regression were included in multivariate logistic regression model, with PSS, NDVI and their interaction term included as predictors. Results: The participants had a mean age of 47.5 years (range 20-99yrs). Of them, 64.1% were women, 59.9% married, 79.4% living with family members (range 1-9 persons) and 80.5% received secondary education or above, . After adjustment for demographic, socioeconomic and lifestyle covariates, perceived stress was a significant predictor on sleep quality (Adjusted odds ratio=1.06 and 1.16, for moderate difficulty and poor sleeper versus good sleep quality, respectively). Interaction term between perceived stress and greenspace coverage was significant. When greenspace coverage increased, the adverse effect of perceived stress on sleep quality decreased. Conclusion: Higher neighborhood greenspace coverage could alleviate the adverse effect of perceived stress on sleep quality in an urban residential population.

## **002.04.10. Greenness and Depressive Symptoms: Air Pollution, Physical Activity, Walking and BMI as Mediators**

Hyeonjin Song

*Hyeonjin Song<sup>3</sup>, Sooyeon Kim<sup>1</sup>, Garam Byun<sup>1</sup>, Hyomi Kim<sup>1</sup>, Honghyok Kim<sup>1</sup>, Sera Kim<sup>1</sup>, Dahyun Baek<sup>1</sup>, Yongsoo Choi<sup>3</sup>, Jong-Tae Lee<sup>2</sup>*

*2. School of Health Policy and Management, College of Health Science, Korea University, Seoul, Korea (the Republic of).*

*3. Public Health Science, Korea University, Seoul, Korea (the Republic of).*

**Abstract: Background/Aim** Several mechanisms have been suggested for the association between greenness and mental health. The objective of this study is to examine mediating effect of air pollution, physical activity, walking and BMI on the relationship between residential greenness and depressive symptoms. **Methods** This study was based on Korean Community Health Survey 2009 with individuals of general adults in the seven major cities of Korea (N=64,127). Individuals with Center for Epidemiological Studies Depression (CES-D) score  $\geq 16$  were classified as having depressive symptoms. District-level of annual greenness was measured through Normalized Difference Vegetation Index (NDVI) and annual concentrations of PM10 were obtained. **Results** In the regression analysis, controlling for potential confounders, the odds ratio of having depressive symptoms was 0.812 (95%CI: 0.776, 0.849) with an interquartile range (17.61) increase of NDVI. When additionally adjusted for walking (more than or equal to 5 days a week and more than 30 minutes per day) or concentration of PM10, the parameter estimate for NDVI changed about 5.9% and 3.4%, respectively. For physical activity and BMI, the results did not change. **Conclusions** Our findings suggest protective impact of urban greenness on depressive symptoms. The evidence for mediating effect of walking and air pollution was meager for individuals in South Korea. Unknown pathways may explain the impact of greenness besides walking and mitigation of air pollution. This study suggests that exposure to greenness could have positive impact on mental health.

## 002.04C. Indicators of Cumulative Risks

### **002.04.11. Effects of Climate Change on Co-Occurrences of Allergenic Pollen and Photochemical Air Pollutants in the United States**

Ting Cai

*Ting Cai<sup>1</sup>, Xiang Ren<sup>1</sup>, Yong Zhang<sup>1</sup>, Zhongyuan Mi<sup>1</sup>, Panos Georgopoulos<sup>1</sup>*

*1. Environmental and Occupational Health Sciences Institute (EOHSI), Rutgers University, Piscataway, NJ, United States.*

**Abstract:** Ambient air quality has been substantially impacted by climate change over the past few decades. In fact, climate change critically affects both the atmospheric processes involved in the dynamics of air pollution systems and the dynamics of biogenic emissions including trees and grass pollens and fungal spores. Furthermore, the prevalence of Allergic Airway Disease (AAD) is growing globally, resulting in increased numbers of emergency department visits and hospitalizations. Clinical studies show that AAD can be exacerbated by the synergistic action of aeroallergens such as pollen and spores, and atmospheric pollutants such as ozone. Previous studies, involving data from nationwide observations of airborne pollen counts of selected plant species in conjunction with climatic factors, indicated that the start date and length of pollen season, the average peak value and the annual total of daily airborne pollen counts have been affected by the changing climate. The present study investigates co-occurrences of ozone exceedance and allergenic pollens across the contiguous United States (ConUS). Analyses of observed pollen counts and ozone concentrations at 58 pollen monitor stations were conducted. Also, emissions and concentrations of pollens in base years (2004) and future years (2047) were simulated with a customized version of CMAQ (the Community Multiscale Air Quality model) employing a grid with 36 km by 36 km horizontal resolution, while corresponding ozone concentrations at the same resolution for the above timeframes were conducted by a multi-university/agency consortium including USEPA. This study employed spatiotemporal correlation analysis to examine patterns of co-occurring ozone and pollen concentrations; the outcomes of this analysis provide information that can support development of strategies for managing health-impacts of co-occurring photochemical pollutants and aeroallergens.

## **O02.04.12. Association between Multiple Environmental Factors with Neurological Diseases in Metro Vancouver, British Columbia, Canada**

Weiran Yuchi

*Weiran Yuchi<sup>1</sup>, Hind Sbihi<sup>1</sup>, Hugh W Davies<sup>1</sup>, Lillian Tamburic<sup>1</sup>, Michael Brauer<sup>1</sup>*

*1. School of Population and Public Health , The University of British Columbia , Vancouver , BC, Canada.*

**Abstract:** Background: Limited evidence suggests the potential for associations between air pollution with neurodegenerative disorders such as Multiple Sclerosis (MS), Parkinson's Disease (PD) and dementia. Further, other environmental factors such as noise and green spaces have yet to be examined. Objectives: We aim to assess the effects of spatially co-varying environmental exposures - noise, nitrogen dioxide (NO<sub>2</sub>), fine particulate matter (PM<sub>2.5</sub>) and green space - on the incidence of MS, PD and dementia in the Vancouver, British Columbia (BC), Canada metropolitan region. Here we present initial analyses for MS. Methods: Cases and age- and sex-matched controls were identified in a population-based (N = 674,176) cohort of adults derived from health insurance records. Incident cases from 1999 to 2002 were identified by relevant diagnostic codes and pharmaceutical dispensation data. Environmental exposures were assigned to each study subject based on their residential postal codes, accounting for changes in residence. We applied conditional logistic regression to estimate the increased odds of developing MS, PD and dementia in relation to an interquartile range increase in exposures, while adjusting for neighborhood level median income level. Results: Compared to their matched controls, MS cases (N = 289) were increased by 21% (95% CI: 0.79, 1.86) in relation to noise exposure, and by 11% (95% CI: 0.79, 1.55) and 7% (95% CI: 0.76, 1.52) for NO<sub>2</sub> and PM<sub>2.5</sub> respectively. A change in neighborhood green space was associated with a 38% decrease in the odds of a MS case (OR= 0.62, 95% CI: 0.38, 0.98). Conclusions: Noise and air pollution exposure may increase the risk of MS incidence while neighborhood green space had a protective effect.

### **002.04.13. A Novel Distributed Approach to Characterize Community Characteristics and Environmental Exposures in the Multi-Site Children's Respiratory and Environmental Workgroup (CREW)**

Patrick Ryan

*Patrick Ryan<sup>1</sup>, Cole Brokamp<sup>1</sup>, Jeff Blossom<sup>2</sup>, Nathan Lothrop<sup>3</sup>, Paloma Beamer<sup>3</sup>, Rachel Miller<sup>4</sup>, Cynthia Visness<sup>5</sup>, Antonella Zanobetti<sup>6</sup>, Diane Gold<sup>7</sup>, James Gern<sup>8</sup>*

**Abstract:** Background: Assessing community and environmental exposures based on location is a significant challenge in multi-site studies due to restrictions in sharing private health information. Our objective was to develop a reproducible and distributed method to derive community characteristics, including measures of disparities, for the Children's Respiratory and Environmental Workgroup (CREW), a multi-site consortium of birth cohorts participating in the NIH ECHO program. Methods: We used a software containerization platform to enable individual sites to geocode their participants' birth record addresses and link these to community characteristics. Census tract-level information regarding race, ethnicity, education, housing, and other indicators of disadvantage was obtained from the decennial U.S. census in 1990, 2000, and 2010. These data, combined with a TIGER/Line address range geocoder, census tract boundaries, and analysis code were containerized and distributed to individual CREW sites. Each site utilized the software to assign tract-level information to participants' birth addresses, removed identifiers, and returned the data to a central site for analysis. Results: Birth addresses for 6,504 children enrolled in eight cohorts were linked to tract-level information using our containerized software. Collectively, the mean percentage of households below the poverty level in participants' census tracts was 15%; this varied across cohorts from 5% to 28%. The overall mean and range of census tract percentage of white population, single parent households, and unemployed adults was 67% (23-93%), 22% (12-39%), and 10% (5-16%), respectively. Conclusion: The custom software designed for CREW allowed the consortium to derive community characteristics across cohorts while maintaining participant confidentiality and HIPAA compliance. The approach will be expanded to address histories acquired longitudinally and to derive and analyze additional environmental exposures.

## **O02.04.14. The Development of a Cumulative Stressors and Resiliency Index (CSRI) to Examine Environmental Health Risk: A South Carolina Assessment**

Kristen Naney

*Kristen B. Naney<sup>1</sup>, Sacoby M. Wilson<sup>1</sup>, Xin He<sup>1</sup>, Amir Sapkota<sup>1</sup>, Robin C. Puett<sup>1</sup>*

*1. Maryland Institute for Applied Environmental Health, University of Maryland, College Park, MD, United States.*

Abstract: Several South Carolina (SC) communities are overburdened by pollution and may suffer from environmental health disparities. They may also lack access to resiliency buffers (community assets) that can counteract negative environmental exposures. To effectively address this double disparity, improvements in screening approaches and cumulative risk assessment (CRA) methods are needed to better understand and mitigate risk. The purpose of this study was to develop a cumulative stressors and resiliency index (CSRI) to rank human health and environmental risks at the census tract level in SC. We performed Principal Component Analysis (PCA) on variable subcategories to reduce the proposed indicators to 20 that reflected environmental stress and resiliency in communities impacted by environmental injustice. CSRI scores (0 - 100) were computed at the census tract level and high-risk (HR) census tracts were identified as CSRI scores in the 90th percentile. We performed a one-way analysis of variance (ANOVA) on CSRI scores by Environmental Affairs (EA) region and linear regression for percent non-white and CSRI scores. Choropleth maps were developed in ArcMap 10.5 using natural breaks to visualize spatial relationships. CSRI scores ranged from 7.4 - 64.0. The mean CSRI score for SC was 29.1, which was lower than the mean score for Upstate (35.2) and Midlands (31.7) regions. The one-way ANOVA results indicated a statistically significant difference in CSRI scores by EA region ( $p < 0.0001$ ) except between the Lowcountry and Pee Dee regions [95% CI: -1.53, 2.68]. Based on the regression results, a one-unit increase in the percentage of non-white populations per census tract increased CSRI scores by roughly 6.1%. The results of our study provide a blueprint for targeting low resiliency communities for public health interventions and supports the inclusion of resilience factors in environmental justice (EJ) assessments.

## **O02.04.15. Cumulative Risk and Impacts Modeling on Environmental/Chemical and Social Stressors**

Aolin Wang

*Hongtai Huang<sup>1</sup>, Aolin Wang<sup>1</sup>, Rachel Morello-Frosch<sup>2</sup>, Juleen Lam<sup>1</sup>, Marina Sirota<sup>3</sup>, Amy M. Padula<sup>1</sup>, Tracey Woodruff<sup>1</sup>*

*1. Obstetrics, Gynecology & Reproductive Sciences, University of California, San Francisco, San Francisco, CA, United States.*

*2. Environmental Science, Policy, and Management, University of California, Berkeley, Berkeley, CA, United States.*

*3. Institute for Computational Health Sciences, University of California, San Francisco, San Francisco, CA, United States.*

**Abstract:** Background: A growing literature has emerged in recent years that evaluates combined health effects of environmental exposures and social stressors. To identify and incorporate the potential impacts of such joint exposures is critical in cumulative risk assessment and impact studies, but creates analytical challenges. A review of cumulative risk and impacts modeling techniques on environmental/chemical and social stressors can provide useful modeling reference for the progression of future cumulative risk and impact studies. Methods: We conducted a review to identify the types of statistical models utilized in cumulative risk and impact modeling in environmental health studies. The specific review question was: What are the existing quantitative methods used to examine the cumulative impacts of exposures to both environmental/chemical and social stressors on health? We conducted a systematic search over the period of 1 January 2012 through 21 June 2017 to identify original peer-reviewed research articles that evaluate both environmental and social stressors and analyzed their health effects. We focused on human subject studies where information regarding quantitative method used was reported. Results: Among the 376 articles found, we identified 31 eligible articles of which the majority used simple regression models. Multilevel/hierarchical models, generalized linear regression models, and some unsupervised methods were also utilized in some previous studies. Air pollutants and socioeconomic factors, especially race/ethnicity and income level, were among the most frequently evaluated chemical and non-chemical stressors. Mortality rate, cancer risk, and adverse pregnancy outcomes were the most frequently evaluated health effects. Conclusions: With appropriate study design and modeling assumptions, we recommend that additional data mining methods may be useful to better characterize combined effects of environmental and social stressors for risk assessment.

## O02.04D. Integration of Chemical Transport and Dispersion Models to Improve Spatiotemporal Air Pollution Estimates

### **O02.04.16. Combining Satellite Imagery and Numerical Model Simulation Results to Estimate Daily Ambient Air Pollution: An Ensemble Averaging Approach**

Howard Chang

*Nancy Murray<sup>1</sup>, Howard Chang<sup>1</sup>, Heather Holmes<sup>2</sup>, Yang Liu<sup>1</sup>*

*1. Emory University, Atlanta, GA, United States.*

*2. University of Nevada, Reno, Reno, NV, United States.*

**Abstract:** Background: Ambient fine particulate matter less than 2.5  $\mu\text{m}$  in aerodynamic diameter (PM<sub>2.5</sub>) has been linked to various adverse health outcomes. However, the sparsity of air quality monitors greatly restricts the spatio-temporal coverage of PM<sub>2.5</sub> measurements and limits the accuracy of PM<sub>2.5</sub>-related health studies. Methods: We develop a method to combine estimates from two current data integration approaches for PM<sub>2.5</sub> using satellite-retrieved aerosol optical depth (AOD) and simulations from the Community Multi-scale Air Quality (CMAQ) modeling system. Previous methods utilize either AOD or CMAQ separately or use a multi-stage approach where prediction error is difficult to quantify. We aim to leverage advantages offered by both methods in a unified modeling framework. Borrowing from weather forecasting techniques, we adapt Bayesian ensemble averaging to statistical downscaler models. The cross-validated predictive performance for AOD and CMAQ at a single monitor determines the spatially varying averaging weights, which are then extended to a full spatial region using kriging. Results: Analysis of 63 monitoring locations in the southeastern United States from 2003 to 2005 indicates good predictive performance of 1 km AOD and 12 km CMAQ downscalers individually with R<sup>2</sup> values of 0.78 and 0.81 in 10-fold cross-validation experiments; the ensemble averaging approach increased overall R<sup>2</sup> up to 0.83. This approach also shows that the usefulness of AOD and CMAQ differs spatially, as evidenced by estimated averaging weights varying from approximately 0.3 to 0.9 for CMAQ. Conclusion: The ensemble framework can be used to improve exposure assessment and subsequently inform health effect estimation and health impact analyses; it also provides prediction intervals, which are often not available from previous methods. The approach herein is highly applicable for estimating other environmental risks, such as ambient temperature and heavy precipitation.

## **O02.04.17. A Hybrid Modeling Framework to Estimate Traffic-Related Exposure in Three Connecticut Cities**

Kristina Wagstrom

*Fatema Parvez<sup>1</sup>, Kristina Wagstrom<sup>1</sup>*

**Abstract:** Traffic-related air pollution is one of the major challenges facing urban areas. As traffic-related emissions result in air pollutant concentrations that vary over spatial scales of under 100m, it is challenging to implement models to capture this behavior. In this study, we develop a hybrid modeling framework combining a regional model (CAMx) and a local scale dispersion model (RLINE) to estimate concentrations of both primary and secondary species from roadway emission sources. We use the Particulate Matter Source Apportionment Technology (PSAT) to quantify the concentrations from traffic-related emission sources. We employ RLINE to estimate pollutant distribution profiles for traffic-related emissions for typical diurnal conditions each month at a fine resolution. We use the traffic-related contributions from CAMx-PSAT alongside the profiles from RLINE to distribute the traffic-related contributions spatially and temporally. This allows us to efficiently estimate air pollutant concentrations at fine spatial (40mx40m) and hourly temporal resolution. We conduct a model evaluation of our framework for NO<sub>2</sub> in the year 2011 using both satellite data and regression model estimates at census block resolution. We have applied this modeling framework to three cities in Connecticut (Hartford, New Haven, and Windham) and quantified human exposure to NO<sub>x</sub>, PM<sub>2.5</sub>, and elemental carbon. We also assess the health risk associated with each species for individuals of different age and genders. Finally, we quantify the environmental inequality based on income and population density. Our approach using a dispersion model is unique as it uses the mass fraction of the total dispersed pollutant at different receptor points and hence is not dependent on extensive roadway emissions data or extensive model runs. This modeling approach overcomes two major challenges facing modeling for traffic-related exposures: double counting emissions and a lack of temporal variability.

## **O02.04.18. Modelling the Intra-Urban Variability of NO<sub>2</sub> for Estimating Human Exposure in Guangzhou, China**

Baihuiqian (Vera) He

*Baihuiqian (Vera) He<sup>1</sup>, Stefan Reis<sup>1</sup>, Mathew Heal<sup>1</sup>*

*1. Chemistry, The University of Edinburgh, Edinburgh, United Kingdom.*

Abstract: NO<sub>2</sub> concentrations within cities are known to have high spatio-temporal variation and estimating intra-urban variability of NO<sub>2</sub> accurately is important for human exposure assessments. Land-use regression (LUR) and dispersion models (DM) are widely used for estimating air pollution exposure. Few models have been developed in China on this scale due to scarcity of input data, especially from monitoring data. Integration of LUR with DM can help to overcome the lack of data. The aim of this study is to use both LUR and DM, including in combination, to simulate NO<sub>2</sub> concentrations for the city of Guangzhou and to explore the differences between modelled results. NO<sub>2</sub> observations at 10 sites are obtained from <http://beijingair.sinaapp.com> for 2017. Hourly concentrations are averaged to annual mean values. DM with ADMS-Urban is applied in Guangzhou using input data including emissions from Multi-resolution Emission Inventory for China (MEIC), road geometry from OpenStreetMap, and hourly meteorological data from the National Oceanic and Atmospheric Administration (NOAA). The results are validated using NO<sub>2</sub> observation, which are also used to develop a LUR model. Using a geographic information system, spatially explicit predictor variables in different buffer zones are regressed against monitoring data. The predictor variables include road networks, land-use classification, and population density. A stepwise multiple regression approach is used with a priori-defined predictor variables. These predictor variables are selected to maximize the adjusted percentage explained variance (R<sup>2</sup>). Model performance is evaluated by leave-one-out cross-validation. In the integrated model, DM generated concentrations of NO<sub>2</sub> at various receptors are used to develop LUR models. Modelled concentrations of the three approaches are compared with the aim to determine the best approach to derive urban pollution maps of NO<sub>2</sub> over the city to assess population exposure.

## **O02.04.19. Brown Coal Mine Fire-Related Fine Particulate Matter and Medical Service Utilisation in Australia: A Time Series Analysis**

Yuming Guo

*Amanda Johnson<sup>1</sup>, Joanna Dipnall<sup>1</sup>, Martine Dennekamp<sup>1</sup>, Grant Williamson<sup>2</sup>, Caroline Gao<sup>1</sup>, Matthew Carroll<sup>1</sup>, Christina Dimitriadis<sup>1</sup>, Jillian Ikin<sup>1</sup>, Fay Johnston<sup>2</sup>, Alexander McFarlane<sup>3</sup>, Malcolm Sim<sup>1</sup>, Dion Stub<sup>1</sup>, Michael J Abramson<sup>1</sup>, Yuming Guo<sup>1</sup>*

- 2. University of Tasmania, Hobart, TAS, Australia.*
- 3. University of Adelaide, Adelaide, SA, Australia.*

**Abstract:** Background: There is a knowledge gap as to whether coal mine fire smoke has adverse health risks. This study aimed to assess the association between coal mine fire-related PM<sub>2.5</sub> and health service utilisation across five localities in South-eastern Victoria, Australia after wildfires ignited a coal mine fire which burned for six weeks in 2014. Areas in the immediate vicinity of the mine were estimated to experience hourly mine fire-related PM<sub>2.5</sub> concentrations of up to 3700 µg/m<sup>3</sup>. Methods: Data on medical service utilization between 2012 and 2016 were collected from the Medicare Benefits Schedule; a national database of use of medical services. Spatially resolved PM<sub>2.5</sub> concentrations were retrospectively modelled using The Air Pollution Model (TAMP), a dispersion model, coupled with a Chemical Transport Model. Poisson distributed lag time series analysis examined the association between daily mine fire-related PM<sub>2.5</sub> concentrations and medical service utilization for respiratory, cardiovascular and mental health conditions. Confounders included seasonality, long-term trend, day of the week, maximum ambient temperature and public holidays. Results: Positive associations were found between mine fire-related PM<sub>2.5</sub> and all medical service types, after lag 2-5 days. A 10 µg/m<sup>3</sup> increase in PM<sub>2.5</sub> was associated with a 19% (95%CI 16-22%) increase in the risk of long and short General Practice consultations, 29% (17-42%) increase in cardiovascular services, 27% (10-46%) increase in respiratory services and 13% (4-22%) increase in mental health consultations. Conclusions: Coal mine fire-related PM<sub>2.5</sub> exposure was associated with increased use of medical services for respiratory, cardiovascular and mental health. These findings can inform the development of future public health policy responses in the event of major air pollution episodes.

## **002.04.20. Estimating Exposure to Air Pollution for Long and Short Term Health Effects Using Coupled Regional and Local Scale Dispersion Models - CMAQ-Urban**

Sean Beevers

*Sean D. Beevers<sup>3</sup>, Nutthida Kitwiroon<sup>3</sup>, Andrew Beddows<sup>3</sup>, Evangelia Samoli<sup>4</sup>, Benjamin Barratt<sup>1</sup>, Joel D. Schwartz<sup>2</sup>, Klea Katsouyanni<sup>3</sup>*

- 2. Harvard School of Public Health, Harvard, Boston, MA, United States.*
- 3. Population Health and Environmental Sciences, King's College London, London, United Kingdom.*
- 4. National and Kapodistrian, University of Athens, Athens, Greece.*

**Abstract:** Background: Recent developments in coupling regional and local scale dispersion models enable address level estimates of exposure to be made each day over many years, and from city streets to continental scales. These models can be used to estimate both long and short term health effects for a range of pollutants including: PM<sub>2.5</sub>, PM<sub>10</sub>, NO<sub>X</sub>, NO<sub>2</sub> and O<sub>3</sub>, as well as PM components. Methods: As part of the UK Medical Research Council funded, Comparative evaluation of Spatio-Temporal Exposure Assessment Methods for estimating the health effects of air pollution (STEAM) project, we have used the Eulerian Community Multiscale Air Quality model (CMAQ), coupled to the local scale Atmospheric Dispersion Modelling System (ADMS) roads model. We will present the novel modelling approaches and methods used to create the coupled model, demonstrating its use at city to continental scales. Results: Using the model, we have predicted hourly and daily air pollution concentrations for 5 years at 20m spatial resolution over London, as well as annual average concentrations at 20m scale across Europe. Comparison with fixed site measurements (from kerbside to rural) across London show that the model performs well, having daily r values of 0.86 (NO<sub>X</sub> and NO<sub>2</sub>), 0.79 (O<sub>3</sub> 8hr), 0.67 (PM<sub>10</sub>) and 0.94 (PM<sub>2.5</sub>) and a normalised mean gross error of 0.28 (NO<sub>X</sub>), 0.25 (NO<sub>2</sub>), 0.24 (O<sub>3</sub> 8hr), 0.2 (PM<sub>10</sub>) and 0.17 (PM<sub>2.5</sub>). Conclusions and future work: The coupling of regional and local scale models provides an efficient solution to air pollution predictions at all of the relevant spatial and temporal scales for public health research. However, a significant limitation of the modelling approach is the development of detailed emissions inventories, especially for road transport. We will also discuss our approach to developing detailed traffic emissions using satellite data, as part of an on going European Space Agency project.

## 002.04E. Prenatal Pesticide Exposure

### 002.04.21. Dietary and Non-Dietary Predictors of Pyrethroid Pesticides in a Cohort of Urban Pregnant Women

Pam Factor-Litvak

3. *Biostatistics, Mailman School of Public Health, New York, NY, United States.*
4. *Department of Environmental Medicine and Public Health, Icahn School of Medicine, Mount Sinai, New York, NY, United States.*

**Abstract:** Pyrethroids and organophosphate pesticides are used in agriculture and residential areas to protect crops and reduce the transmission of insect-borne diseases. We aimed to investigate dietary and non-dietary predictors of pyrethroid and organophosphate urinary concentrations of five biomarkers (3-PBA, PNP, CPM, OPM, and 24-D) among healthy pregnant women aged 16-35 living in New York City. Urinary pesticides biomarkers of 153 women who participated in the Thyroid Disruption and Infant Development Study were measured. We imputed the median) subsequently to assess their association with dietary and non-dietary predictors. Baseline demographic and dietary data were collected from all women at the time of recruitment in prenatal clinics. After excluding cases with missing values on dietary and non-dietary predictors, 137 participants were included in our analysis. Ordinal logistic regression models with dietary and non-dietary predictors were used to predict level of biomarker; in these models odds ratios under 1.0 represent increased odds. The proportional odds assumption held. For each year increase in maternal age, the odds of having higher concentrations of 24-D was higher [OR=0.92 (95%CI: 0.85,0.98)]. Hispanic women had higher odds of having lower concentrations of CPM and OPM [OR=5.0 (95%CI: 1.70,14.73), [OR=3.43 (95%CI: 1.24,9.51)]. Dietary variables predicted the concentration of PAR. Mothers who reported eating any organic products had higher odds of having higher urinary levels of OPM compared to those who did not [OR=0.36 (95%CI: 0.14, 0.94)]. Age and ethnicity predict pyrethroid and organophosphate concentrations in this population of pregnant women. Our intriguing finding of higher concentrations of OPM in mothers who report eating organic products requires confirmation in future work with more detailed dietary assessments.

## **O02.04.22. Effect of a Longitudinal, Randomized Organic Diet Intervention on 2,4-D, Pyrethroid and Organophosphate Pesticide Exposures among Pregnant Women**

Cynthia Curl

*3. Department of Environmental and Occupational Health Sciences, University of Washington, Seattle, WA, United States.*

**Abstract:** Background: Several short-term (1-2 week) interventions in children and adults have shown that introduction of a fully "organic" diet can significantly reduce pesticide exposure. Objectives: We assessed the effect of a long-term (6 month) organic diet intervention on pesticide exposure among pregnant women. We supplemented women's existing diets with weekly deliveries of either organic or conventional produce to reflect real-world consumption patterns. We hypothesized that pesticide exposure would be lower in the organic group. Methods: We recruited 20 women in their first trimesters of pregnancy. Eligible women were non-smokers aged 18-35 who reported eating exclusively conventionally-grown food. Participants were randomized to receive weekly deliveries of either organic or conventional produce throughout their second and third trimesters. They completed daily food diaries and provided weekly spot urine samples. Urine samples were pooled to represent monthly exposures and analyzed for eight biomarkers representing exposure to one herbicide, seven organophosphates and eight pyrethroid insecticides. Results: We collected an average of 23 weekly samples per participant, for a total of 461 individual samples. We detected p-nitrophenol (PNP), 2,4-dichlorophenoxyacetic acid (2,4-D,) and 3-phenoxybenzoic acid (3-PBA) in 99%, 90%, and 74% of samples, respectively. Long-term average concentrations of 2,4-D and 3-PBA were significantly lower in women in the organic group compared to the conventional group (2,4-D: 0.36 vs 0.57 µg/L, p=0.05; 3-PBA: 0.70 vs 2.21 µg/L, p=0.02). PNP concentrations were also lower in the organic group, but this difference was not significant (0.54 vs 0.63 µg/L, p = 0.3). Conclusion: This is the first long-term organic diet intervention study and the first to evaluate pregnant women. Concentrations of 2,4-D and 3-PBA were significantly reduced in women whose diets were supplemented with organic produce compared to those receiving conventional produce.

## 002.04.23. Maternal Residential Pesticide Use and Risk of Childhood Leukemia in Costa Rica

Abstract: Evidence suggests that early-life exposure to pesticides inside the home may be associated with childhood leukemia, however data from Latin American countries are limited. We examined whether self-reported maternal residential pesticide use and nearby pesticide applications--before and after child's birth--were associated with acute lymphoblastic leukemia (ALL) in the Costa Rican Childhood Leukemia Study (CRCLS), a population-based case-control study (2001-2003). Cases (n=251 ALL) were diagnosed between 1995 and 2000 (age <15 years at diagnosis) and were identified through the Costa Rican Cancer Registry and National Children's Hospital. Population controls (n=577) were drawn from the National Birth Registry. We fitted unconditional logistic regression models adjusted for child sex, birth year, and socioeconomic status to estimate the exposure-outcome associations and also stratified by child sex. We observed that self-reported maternal insecticide use inside the home in the year before pregnancy, during pregnancy, and while breastfeeding was associated with increased odds of ALL among boys [adjusted Odds Ratio (aOR) = 1.63 (95% Confidence Interval (95% CI)): 1.05-2.53], 1.75 (1.13-2.73), and 1.75 (1.12-2.73), respectively]. We also found evidence of exposure-response relationships between more frequent maternal insecticide use inside the home and increased odds of ALL among boys and girls combined. Maternal report of pesticide applications on farms or companies near the home during pregnancy and at any time period were also associated with ALL. This study in Costa Rica highlights the need for education to minimize pesticide exposures inside and around the home, particularly during pregnancy and breastfeeding.

## 002.04.24. Pyrethroid Metabolites during Pregnancy and Longitudinal Child Behavior in the Cincinnati HOME Study

Melissa Furlong

5. Northeast Ohio Medical University, Rootstown, OH, United States.

**Abstract:** Pyrethroids are the most commonly used residential insecticides in the United States. Although toxicological and cross-sectional studies report overall and sex-specific associations between pyrethroids and behavior in animals and humans, longitudinal epidemiological reports are scarce. We used the Cincinnati HOME Study to examine associations of urinary pyrethroid metabolites (3-PBA, trans-DCCA, 4F-PBA) at 16 and 26 weeks of pregnancy with child behavior measured with the BASC-2 and BRIEF(-P) at 3, 4, 5, and 8 years (n=301). We examined continuous measures of log 3-PBA and creatinine-adjusted 3-PBA quartiles. Since detection frequencies for 4F-PBA and trans-DCCA were <20%, we dichotomized these at the LOD. We used linear mixed effects regression with a random intercept for participant, and fixed effects of maternal education, race, smoking, mother's age, home environment, visit age, creatinine, and fresh fruit and vegetable consumption. We evaluated modification by sex ( $\alpha=0.05$ ). There were no consistent overall associations between any metabolite and behavior. However, 16 (but not 26) week urinary 3-PBA and 4F-PBA concentrations were modified by sex. Dose-response relationships among girls for 3-PBA at 16 weeks were driven by the 4th quartile (Externalizing Composite Q4  $\beta=4.79$ , 95% CI 1.61, 7.96,  $p$  trend=0.04; Aggression Q4  $\beta=3.22$ , 95% CI 0.08, 6.36,  $p$  trend=0.03; Hyperactivity Q4  $\beta=5.16$ , 95% CI 1.93, 8.40,  $p$  trend<0.01; Inhibitory Control Q4  $\beta=4.67$ , 95% CI 0.80, 8.53,  $p$  trend=0.03). Detection of 4F-PBA at 16-weeks was associated with the Behavioral Symptoms Index ( $\beta=3.38$ , 95% CI 0.65, 6.11), Attention ( $\beta=3.40$ , 95% CI 0.70, 6.10), Hyperactivity ( $\beta=3.19$ , 95% CI 0.29, 6.09), and Working Memory ( $\beta=4.74$ , 95% CI 0.79, 8.68) among girls but not boys. Sex interaction p-values were <0.05 for 4F-PBA and both 3-PBA variables in above models. Pyrethroid exposures during early pregnancy may be associated with the development of ADHD-related behaviors during childhood, in girls.

## **002.04.25. Insecticide Exposure and Infant Visual Function**

Monica Silver

*Monica K. Silver<sup>1</sup>, Jie Shao<sup>2</sup>, Minjian Chen<sup>3</sup>, Yankai Xia<sup>3</sup>, Betsy Lozoff<sup>4</sup>, John Meeker<sup>1</sup>*

- 4. Center for Human Growth and Development, University of Michigan, Ann Arbor, MI, United States.*

**Abstract:** Introduction: Fetal and infant brains are rapidly developing, yet the neurodevelopmental effects of early-life exposure to many commonly used insecticides are largely unknown. Here we examined the effects of prenatal insecticide exposure on infant grating visual acuity (VA), an important indicator of visual pathway development. Methods: 15 insecticides and acaricides of various classes were measured in umbilical cord blood plasma from a cohort of infants in Fuyang County, China (n=195). Binocular grating VA was measured using the Teller Acuity Card (TAC) preferential looking procedure at 6 weeks, 9 months, and 18 months. Insecticides were analyzed as 3-level ordinal (non-detect [ND]/medium/high), or dichotomous (ND/detect), depending on detection rates. Generalized linear and linear mixed models were used to evaluate relationships between pesticides and VA throughout infancy. Logistic regression was used to explore effects of prenatal exposure on visual impairment (as defined by ICD-10) at 18 m. Results: Propoxur, prothiofos, aldrin, and DDT metabolites, DDE o,p and DDE p,p, were detected in 100, 59.4, 84.2, 32.1, and 10.3% of samples, respectively. Infants prenatally exposed to high propoxur, aldrin, and DDE p,p all had lower VA scores (vs. ND) at the two early time points (6 wks and 9 m). Infants with prenatal exposure to prothiofos had lower VA scores (vs. ND) at all three time points. VA scores were significantly lower at 6 wks;  $\beta$  (95%CI),  $p = -0.19$  (-0.36, -0.03),  $p = 0.02$  and  $-0.09$  (-0.25, 0.07),  $p = 0.28$ , for high and medium prothiofos vs. ND, respectively; overall  $p$ -trend=0.02. Prothiofos-exposed infants also had increased odds of visual impairment at 18 months; OR (95%CI),  $p = 2.79$  (1.21, 6.41), for medium prothiofos vs. ND. Conclusions: Prenatal exposure to the organothiophosphate prothiofos was associated with deficits in infant grating VA. Delayed visual pathway maturation could potentially negatively affect downstream cognition.

Abstract: The World Health Organization (WHO) recently estimated that ambient air pollution causes 482,000 premature deaths within the WHO European Region. However, the significant potential health and societal costs of poor mental health in relation to air quality is not represented in the WHO report. This reflects the limited number of studies directly linking air pollution exposure to adverse mental health outcomes published to date. The aim of the study is to address the gaps of existing literature and quantify the effect of medium-term exposure of residential traffic air pollution at address level on common mental and psychiatric disorders as well as on physical health. A longitudinal mental health survey was conducted of 1,698 adults living in 1,075 households in South East London, from 2008 to 2013. High-resolution (20m x 20m) residential address level air pollution metrics were employed with the use of the established King's College London urban dispersion model. Data were analysed with the use of multilevel generalised linear models. Average air pollutant exposures across the time period of the study area were 43 µg/m<sup>3</sup> nitrogen dioxide (NO<sub>2</sub>), 79 µg/m<sup>3</sup> nitrogen oxides (NO<sub>x</sub>), 22 µg/m<sup>3</sup> particulate matter with aerodynamic diameter <2.5 µm (PM<sub>2.5</sub>), 23 µg/m<sup>3</sup> particulate matter with aerodynamic diameter <10 µm (PM<sub>10</sub>), and 32 µg/m<sup>3</sup> ozone (O<sub>3</sub>). We found strong evidence for interquartile range increases in PM<sub>2.5</sub>, NO<sub>2</sub>, NO<sub>x</sub> to be associated with 18% to 38% increased odds of common mental disorders, 18% to 29% increased odds of poor physical health, and 15% to 25% of psychotic experiences based on standardised and validated questionnaires, after adjusting for large number of confounders, including individuals socioeconomic position and urban noise. These longitudinal associations were more pronounced in the subset of non-movers. The findings suggest that air pollution from road traffic in London is adversely affecting mental and psychiatric disorders and physical health.

## **O02.04.32. Triggering of Neurodegenerative Hospital Admissions and Emergency Room Visits by Fine Particle Concentrations in Six Urban Centers in New York State: The New York State Accountability Study**

Edwin van Wijngaarden

*Edwin van Wijngaarden<sup>1</sup>, Wangjian Zhang<sup>2</sup>, Shao Lin<sup>2</sup>, Philip Hopke<sup>1</sup>, Sally Thurston<sup>3</sup>, Daniel Croft<sup>4</sup>, Stefania Squizzato<sup>1</sup>, Mauro Masiol<sup>1</sup>, David Rich<sup>1</sup>*

- 2. Environmental Health Sciences, University at Albany, SUNY, Albany, NY, United States.*
- 3. Biostatistics and Computational Biology, University of Rochester, Rochester, NY, United States.*
- 4. Medicine, University of Rochester, Rochester, NY, United States.*

Abstract: Emerging evidence has linked exposure to ambient fine particle (PM<sub>2.5</sub>) concentrations with an increased incidence of neurodegenerative conditions such as dementia, Alzheimer's disease (AD), and Parkinson's disease (PD). Previous studies have not examined the association between ambient PM<sub>2.5</sub> concentrations and exacerbations of symptoms, which would further add to the public health burden of these chronic neurodegenerative conditions. Using the Statewide Planning and Research Cooperative System (SPARCS) database, we retrieved all hospital admissions (inpatient) and emergency room visits (outpatient) with a primary diagnosis of one of three neurodegenerative disease subtypes for NYS residents living within 15 miles from PM<sub>2.5</sub> monitoring sites in Buffalo, Rochester, Albany, Queens, Bronx, and Manhattan from 2005-2016. Using quasi-Poisson regression models adjusting for temperature, relative humidity, and secular trends in hospitalization rates, we examined the association between daily inpatient and outpatient neurodegenerative hospitalizations and ambient PM<sub>2.5</sub> concentrations estimated for short-term and long-term time windows: concurrent exposure as well as lagged by 14, 30, 180, and 365 days. A total of 63,287 inpatient admissions and 14,288 outpatient visits for the three neurodegenerative conditions occurred during the study period. Interquartile range (IQR) increases in PM<sub>2.5</sub> concentration were not associated with increased rates of inpatient AD and dementia hospitalizations. However, increased rates of PD hospital admissions were associated with increased PM<sub>2.5</sub> concentrations in the previous 14 days (rate ratio (RR) = 1.04; 95% confidence interval (CI) = 1.00-1.09), and 30 days (RR=1.06; 95% CI=1.00-1.12). For outpatient visits, an increased rate of AD was associated with increased PM<sub>2.5</sub> in the past 365 days (RR=1.77; 95% CI = 1.03-3.03). Thus, ambient PM<sub>2.5</sub> exposure may be associated with exacerbations of symptoms among patients with neurodegenerative disease.

## **002.04.34. Particulate Air Pollutants and Trajectories of Depressive Symptoms in Older Women**

**Abstract:** Depressive symptoms in older adulthood are common, costly, and disabling. Airborne particulate matter with aerodynamic diameter of < 2.5  $\mu\text{m}$  (PM<sub>2.5</sub>) is an environmental source of neuroinflammation and oxidative stress, which may increase depressive symptoms in later life. Previous studies examining this association however, report mixed results. We examined the association between PM<sub>2.5</sub> and longitudinal trajectories of depressive symptoms in a geographically-diverse sample of 1,987 older women (aged 74.5 $\pm$  3.70) without prior depression from the Women's Health Initiative Study of Cognitive Aging. Participants completed up to eight annual assessments of depressive symptoms as measured by the 15-item Geriatric Depression Scale. The Bayesian Maximum Entropy method was used to construct spatiotemporal models to estimate time-varying exposure to ambient PM<sub>2.5</sub> at residential locations over the prior three-years of each assessment. Latent-class mixed models (LCMMs) with latent process score transformation was used to cluster individuals with similar trajectories of symptoms. Each model examined the class-specific main effect of PM<sub>2.5</sub> on depressive symptoms adjusting for socio-demographic factors (age, geographical region, employment status, and race/ethnicity), lifestyles (alcohol use, smoking, exercise), and physical health (diabetes, hypertension, cardiovascular disease, and past hormone use). We identified three clusters of participants: A minimal-depressive symptom group (N=718; 36.1%), an emerging-depressive symptom group (N=290; 14.6%), and a sustained-depressive symptom group (N=979; 49.3%). There were statistically significant class-specific main effects of PM<sub>2.5</sub> with higher exposure associated with more depressive symptoms in the sustained group (Beta<sub>PM<sub>2.5</sub> sustained</sub> = .03; p = .036). These findings suggest that PM<sub>2.5</sub> may increase depressive symptoms among older women with no prior depression and manifested with mild but sustained depressive symptoms in late life.

## **O02.04.35. The Association between Air Pollution and Depression: Evidence from the Ginkgo Evaluation of Memory Study**

Anjum Hajat

- 4. University of Florida, Gainesville, FL, United States.*

**Abstract:** Introduction: Depression is one of the leading causes of morbidity globally. Thus identifying modifiable risk factors for depression is urgently needed. There is growing evidence that air pollution impacts the brain and has been associated with depression and other mental health outcomes. We evaluated the association between several criteria air pollutants and prevalent depression in a cohort of older adults. Methods: The Ginkgo Evaluation of Memory Study (GEMS) is a rich longitudinal cohort of older adults (age 75 and older) recruited from four sites across the US. Depression was measured using the 10 item Centers for Epidemiologic Studies - Depression (CES-D) scale (scores ranged between 0 and 26) approximately every six months for a nine year follow up period. Fine particulate matter (PM<sub>2.5</sub>), coarse particles (PM<sub>10</sub>) and nitrogen dioxide (NO<sub>2</sub>) were predicted from a national universal kriging model which estimated annual average pollutant levels at participant's residential address one to two years prior to enrollment. We modelled depression as a continuous outcome and used linear regression models adjusted for socio-demographic factors, health behaviors and co-morbidities. Results: Preliminary results suggest an interquartile range (IQR) higher level of PM<sub>2.5</sub> (2 µg/m<sup>3</sup>) was associated with 0.2 unit higher score on the CES-D scale (95% confidence interval (CI): 0.06, 0.33). Similar results were seen for PM<sub>10</sub>. An IQR higher NO<sub>2</sub> level (7 ppb) was associated with 0.27 higher score on the CES-D (95% CI: 0.04, 0.50). Additional analyses will evaluate the onset of depression among this population. Conclusions: Although our observed associations are small in magnitude, our study contributes to the existing evidence of a positive association between air pollution and depression. Our study uses a well validated depression measure, robust air pollution predictions and a rich longitudinal cohort of older adults.

## **O02.04.36. Association of Air Pollution with Depressive Symptoms in the Elderly and Effect Modification by Cognitive Performance**

Tamara Schikowski

*Hicran Altug<sup>1</sup>, Anke Huels<sup>1</sup>, Kateryna B. Fuks<sup>1</sup>, Dorothee Sugiri<sup>1</sup>, Tamara Schikowski<sup>1</sup>*

*1. Environmental Epidemiology, IUF-Leibniz Institute of Environmental Medicine, Duesseldorf, Germany.*

**Abstract:** Background: Research regarding the effects of air pollution on depressive symptoms are limited and results are conflicting. Objective: Associations between long-term air pollution exposure and depressive symptoms in the elderly were assessed and whether mild cognitive impairment (MCI) modifies the association of air pollution with depression. Methods: We included 777 elderly women from the SALIA study (age 66-79). Self-reported depressive symptoms were evaluated by the CES-D test score  $\geq 16$  as a dichotomous outcome. Cognitive performance was assessed by the CERAD-Plus test battery. Air pollutant concentrations were assigned to home addresses by ESCAPE land-use regression models. We also estimated road traffic noise exposure as 24h-mean at facade points. Our adjusted logistic regression models included age, body mass index, smoking habit, environmental tobacco exposure at home, educational level, urban/rural living, physical activity, cardiovascular disease, respiratory diseases, diabetes and the CERAD score as covariates. Results: The prevalence of depressive symptoms and MCI were 15.7% and 59.8%, respectively. In pooled sample, we observed significant associations between an interquartile range (IQR) increase of PM<sub>10</sub> (OR= 1.37; 95%CI: 1.07-1.76), PM<sub>2.5</sub> (OR= 1.74; 95%CI: 1.20-2.53), NO<sub>2</sub> (OR= 1.43; 95%CI: 1.04-1.94) and NO<sub>x</sub> (OR= 1.58; 95%CI: 1.14-2.17) with the presence of depressive symptoms. Women with MCI had more air pollution-induced depressive symptoms: PM<sub>10</sub> [OR =1.51 (95% CI: 1.10, 2.07) pint= 0.074], PM<sub>2.5</sub> [OR =1.91 (95% CI: 1.20, 3.05) pint=0.073], NO<sub>2</sub> [OR =1.73 (95% CI: 1.38, 2.64) pint=0.020] and NO<sub>x</sub> [OR =1.78 (95% CI: 1.17, 2.71) pint=0.009]. We found no associations for women without MCI. No associations were found for coarse fraction of PM, PM<sub>2.5</sub> absorbance and noise exposure. Conclusions: Air pollution might affect depressive mood and elderly with MCI might be more prone to develop depression when additionally exposed to air pollution.

## S02.04A. Children's Exposure to SVOC Mixtures in the Home Environment

### S02.04.01. Associations between Placental Brominated Flame Retardant Levels and Birth Outcomes in a NC Cohort

Heather Stapleton

**Abstract:** Brominated flame retardants (BFRs) are ubiquitous, persistent contaminants that accumulate in human tissues and pass from mother to fetus through the placenta. One class of BFRs, polybrominated diphenyl ethers (PBDEs), has a chemical structure that is very similar to endogenous thyroid hormones (THs), and numerous laboratory studies have demonstrated that PBDEs can interfere with thyroid hormone regulation through a variety of different mechanisms. Studies suggest possible relationships between maternal serum BFRs and fetal development, but results have been inconsistent. To evaluate relationships between BFRs concentrations measured in placenta, a potentially more biologically relevant measure of exposure and birth outcomes, we analyzed samples from pregnant women (n=102) from Durham, NC. Women provided serum and placenta samples which were analyzed for BFRs and birth outcome data was abstracted from medical records. In this cohort we found that BFRs, including PBDEs, accumulated to significantly higher levels in placenta associated with male infants compared to female infants, despite no differences in maternal serum levels by fetal sex. We also found that TH levels in human placental tissues were associated with placenta BFRs in a sex-specific manner. We statistically evaluated associations between BFRs (serum and placenta) and continuous measures of birthweight and gestational age while adjusting for relevant covariates. Placenta BFRs were associated with lower birthweight and shorter gestation, particularly among female infants. Baby girls with the highest BDE-153 exposures, for example, were born 1.5 weeks earlier (95% confidence interval: -2.6, -0.3) than those with low levels of BDE-153 in placenta. Associations between serum BFRs and birth outcomes followed similar patterns but were generally weaker. This research has significant implications for understanding the full impact of contaminant exposures on placenta function and fetal development.

## **S02.04.02. Biomarkers of Exposure to Semi-Volatile Organic Compounds (SVOC) among Pregnant Women in Puerto Rico**

John Meeker

Abstract: There is some evidence for widespread environmental contamination in Puerto Rico, as well as increased rates of adverse pregnancy outcomes and child developmental disorders, yet human studies of human exposure on the island are lacking. To better characterize exposure distributions, temporal variability, and predictors of exposure among pregnant women on the island, to date we have collected urine and serum samples from over 1,200 pregnant women as part of the Puerto Rico Testsite for Environmental Contamination Threats (PROTECT) cohort study. Samples are collected at study visits occurring at 18±2, 22±2, and 26±2 weeks gestation, along with extensive questionnaire data. Urinary or serum concentrations of biomarkers of exposure related to a range of SVOCs (including phthalates, phenols, PAH, brominated and phosphorus-containing flame retardants, pesticides, per- and polyfluoroalkyl substances [PFAS], and others) were measured using state-of-the-art analytical chemistry techniques. We found that concentrations of a number of chemicals (e.g., certain phthalates, phenols and PAH) were significantly greater than those among women of reproductive age in the US NHANES study, while others (e.g., PFAS, polybrominated diphenyl ethers [PBDE], polychlorinated biphenyls [PCB], organochlorine pesticides) were lower. Our analysis of predictors (e.g., demographics, housing characteristics, product use) of these biomarker concentrations have revealed a number of significant findings, which may help inform strategies to reduce exposure. We utilized repeated measures of some biomarkers to calculate intraclass correlation coefficients, which can inform future epidemiology studies and exposure assessments. Finally, we explored the degree to which co-exposures to these chemicals, both within and between chemical groups, was present. Future goals of the study include investigating associations between exposure to chemical mixtures and adverse birth and child development outcomes.

### **S02.04.03. PFAS Serum Concentrations in Pregnant Women from North Carolina: Predictors and Associations with Birth Weight and Gestational Age at Birth**

Jessica Craig

*Jessica Craig<sup>1</sup>, Birgit Claus Henn<sup>1</sup>, Kate Hoffman<sup>2</sup>, Heather Stapleton<sup>2</sup>, Catherine Hoyo<sup>3</sup>, Susan Murphy<sup>5</sup>, Xiaoyun Ye<sup>4</sup>, Antonia Calafat<sup>4</sup>, Thomas F. Webster<sup>1</sup>*

Abstract: Per- and polyfluoroalkyl substances (PFAS) are commonly found in consumer products, exposure is ubiquitous. We examined associations between maternal serum concentrations of six PFAS during pregnancy and birth outcomes in 130 mother-child pairs from the North Carolina-based TESIE Study (2009-2011). We used multivariable and weighted quantile sum (WQS) regression models to estimate total and sex-specific associations between birth outcomes and individual and cumulative exposure to maternal serum PFAS concentrations, respectively. Among male offspring, linear and branched perfluorooctane sulfonic acid (n-PFOS and Sm-PFOS, respectively), linear perfluorooctanoic acid (n-PFOA), perfluorohexane sulfonic acid (PFHxS), and perfluorononanoic acid (PFNA) were inversely associated with birth weight and n-PFOS, n-PFOA, Sm-PFOS, and PFNA were inversely associated with gestational age at birth. Among female offspring, only n-PFOA was inversely associated with birth weight, and n-PFOS, n-PFOA, and perfluorodecanoic acid were inversely associated with gestational age at birth. Cumulative prenatal exposure to the six PFAS was inversely associated with birth weight and gestational age at birth [ $\beta = -248.6$ , 95% CI: -454.9, -42.2 grams and  $\beta = -6.3$ , 95% CI: -11.4, -1.3 days, per weighted quartile increase, respectively] among male offspring, with n-PFOA being the most important PFAS for both birth outcomes according to the WQS weights. Among female offspring, cumulative prenatal exposure to PFASs was positively, but imprecisely, associated with birth weight [ $\beta = 76.2$ , 95% CI: -103.3, 255.7 grams per weighted quartile increase] and not associated with gestational age at birth. These results suggest that male offspring may be more susceptible to individual and cumulative prenatal exposure to PFASs than females and that offspring sex is an effect measure modifier of the association between maternal serum PFAS concentration and birth outcomes.

#### **S02.04.04. Using Silicone Wristbands to Assess Children's Exposure to Organophosphate Esters and Brominated Flame Retardants**

Stephanie Hammel

*Stephanie C. Hammel<sup>1</sup>, Allison Phillips<sup>1</sup>, Kate Hoffman<sup>1</sup>, Amelia Lorenzo<sup>1</sup>, Albert Chen<sup>1</sup>, Thomas F. Webster<sup>2</sup>, Heather Stapleton<sup>1</sup>*

- 2. Boston University, Boston, MA, United States.*

Abstract: Organophosphate esters (OPEs) are often used as flame retardants and plasticizers and, like brominated flame retardants (BFRs), are frequently detected in indoor environments. Human exposure to semi-volatile organic compounds (SVOCs), including OPEs and BFRs, is widespread, which is particularly concerning for children who often experience higher exposures than adults and are especially vulnerable to long-term negative health impacts. Silicone wristbands have been used as personal passive samplers to examine adult ambient and occupational exposures to a suite of SVOCs and have the potential to be used as a non-invasive and inexpensive method of measuring personal exposures to chemical mixtures. Previously, among adults, OPEs and polybrominated diphenyl ethers (PBDEs, a class of BFRs) on bands have been significantly and positively associated with metabolites in pooled urine samples and serum biomarkers, respectively ( $r_s=0.4-0.7$ ;  $p<0.01$ ). Here, we examine the utility of wristbands for assessing children's exposure to 6 OPEs and several classes of BFRs. Children ages 3-6 and their families were recruited in 2014-16 as part of a study examining children's exposures to SVOCs. Paired passive air samplers, hand wipes, and dust from the home were collected and analyzed; OPEs on hand wipes were significantly correlated with biomarkers from pooled urine samples ( $r_s=0.2-0.4$ ,  $p<0.05$ ). Wristbands ( $n=75$ ) were also deployed among these children and will be analyzed for OPEs and BFRs. Levels on the bands will also be compared to OPE urinary metabolites, which were previously analyzed in our laboratory, and serum PBDEs. Preliminary analyses among wristbands worn by children in a similar age range indicate that OPEs and BFRs are ubiquitously detectable on the bands (GM=2.6-187.5 ng/g). Results from this study will be used to validate wristbands as a tool for assessing personal exposure among children.

## **S02.04.05. Children's Exposure to SVOCs Mixtures: The TESIE Study**

Kate Hoffman

*Kate Hoffman<sup>1</sup>, Stephanie C. Hammel<sup>1</sup>, Allison Phillips<sup>1</sup>, Amelia Lorenzo<sup>1</sup>, Albert Chen<sup>1</sup>, Antonia Calafat<sup>2</sup>, Xiaoyun Ye<sup>2</sup>, Thomas F. Webster<sup>3</sup>, Heather Stapleton<sup>1</sup>*

- 2. Centers for Disease Control and Prevention, Atlanta, GA, United States.*
- 3. Boston University School of Public Health, Boston, MA, United States.*

**Abstract:** Semi-volatile organic compounds (SVOCs) are used in consumer and personal care products and are detected in most indoor environments. As a result, human exposure to SVOCs is widespread. However, data on exposure determinants and patterns of co-exposure have not been thoroughly explored, particularly for young children. We investigated biomarkers of exposure to SVOCs among children age 3-6 years, who may experience higher exposures and be more susceptible to adverse health outcomes than other age groups. Participants were enrolled in the Toddlers Exposure to SVOCs in Indoor Environments (TESIE) study (n=203 children of whom 181 provided urine and 90 provided serum). We quantified 44 biomarkers of exposure to phthalates, organophosphate esters, parabens, phenols, antibacterial agents and per- and polyfluoroalkyl substances. Of these, 29 were detected in >95% of samples and many were detected at higher median concentrations than previously reported in the U.S. general population. Demographic characteristics were associated with concentration differences. Non-Hispanic white race and higher maternal education were generally associated with lower concentrations, even after adjusting for potential confounding variables. Our results suggest that outdoor temperature at the time of biospecimen collection may be a particularly important and under-evaluated predictor of biomarker concentrations; 11 biomarkers were significantly associated with temperature. A complex correlation structure was observed among biomarkers. By and large, statistically significant correlations between biomarkers of phthalates, parabens, phenols, and OPEs were positive. Conversely, although PFASs were positively correlated with one another, they tended to be negatively correlated with other biomarkers where significant associations were observed. Taken together, our results provide evidence that assessments of SVOC-associated health impacts could address chemical mixtures.

## S02.04B. Diving Deep: Mechanisms of Endocrine Disruptors in Pregnancy and Relevant Biomarkers

### **S02.04.06. Longitudinal Associations between Urinary Phthalate Metabolites and Maternal Hormones in the Protect Pregnancy Cohort**

Amber Cathey

*4. Department of Epidemiology and Biostatistics, University of Georgia School of Public Health, Athens, GA, United States.*

**Abstract:** Phthalates are endocrine disrupting chemicals that may be associated with adverse birth outcomes. Dysregulation of maternal endocrine homeostasis could serve as a mediator between phthalate exposure and adverse birth outcomes. Here we examined associations between maternal exposure to 16 urinary phthalate metabolites and 9 serum hormones measured over two time points during pregnancy (median 18 and 26 weeks gestation). Linear mixed models with random intercepts were used to assess associations between phthalates and hormones. Secondary analyses examined differing effects of phthalate exposure between visits. Triiodothyronine (T3) was significantly associated with all phthalates except mCNP, mEHP, mEP2, MECPTP and MEHHTP. Notably, IQR increases in mECP and mEOHP were associated with an 11.9% increase (95% CI: 6.8, 17.0) and 6.86% increase (95% CI: 3.25, 10.5) in T3, respectively. Corticotropin releasing hormone (CRH) was positively associated with mCPP (% $\Delta$ : 6.93, 95% CI: 2.35, 11.7), mECP (% $\Delta$ : 25.3, 95% CI: 0.72, 55.8), and mEP2 (% $\Delta$ : 32.9, 95% CI: 11.6, 58.2). Significant positive associations were found between numerous phthalate metabolites and free thyroxine (fT4), T4, and the ratio of T3/T4, while an inverse association was found between MEHHTP, a terephthalate metabolite, and progesterone. Testosterone was positively associated with MHBP (% $\Delta$ : 6.07, 95% CI: 1.12, 11.3) and inversely associated with mEP2 (% $\Delta$ : -16.5, 95% CI: -26.8, -4.70). The effects of 8 metabolites on CRH were significantly different between study visits 1 and 3, with associations being consistently positive at visit 1 and negative at visit 3. These results indicate that exposure to phthalates may disrupt the maternal endocrine system during pregnancy, and that timing of exposure may influence the direction of the relationship between phthalate metabolites and maternal hormones.

## **S02.04.07. Association between Exposure to Per- and Polyfluoroalkyl Substances (PFAS) during Pregnancy and Biomarkers of Stress Response in the Maternal-Fetal Unit**

Abstract: In a demographically diverse cohort of 500 pregnant women recruited from two San Francisco hospitals, we used linear regression to evaluate the association between eight PFAS with detection frequency of 50% or greater in our sample, and two biological measures of stress response: 1) telomere length (TL) in umbilical cord blood leukocytes collected at delivery, and 2) corticotropin-releasing hormone (CRH) in maternal plasma collected during the 2nd trimester. Both outcomes were log-transformed. PFAS levels (ug/L) were measured in mother's serum during the 2nd trimester, and also log-transformed. Each chemical was assessed separately since levels were highly correlated. CRH analyses were adjusted for pregnancy complications, mother's age, parity, and race/ethnicity. TL analyses were additionally adjusted for infant sex, and gestational age at birth. We also evaluated the associations separately for Latina and White women. The burden of PFAS exposure was greater among Latinas (30% of participants) than White women (40% of participants) in our study population. PFAS were not associated with TL, expressed as the relative ratio of telomere repeat copy number to single-copy gene copy number. A one unit increase in Perfluoroundecanoic acid (PFUDA) was associated with a 0.14 increase in CRH in race adjusted models (95% CI: 0.04-0.23). Higher levels of Perfluorononanoic acid (PFNA; 0.25, 95% CI: 0.07-0.44), Perfluorooctanesulfonic acid (PFOS; 0.161, 95% CI: 0.003-0.32), 2-(N-Methyl-perfluorooctane sulfonamido) acetic acid (MePFOSAachOH; 0.18, 95% CI: 0.03-0.34), Perfluorohexane sulfonic acid (PFHxS; 0.20, 95% CI: 0.02-0.38), and PFUDA (0.38, 95% CI: 0.19-0.57) were all significantly associated with higher CRH among Latinas. Higher levels of Perfluorooctanesulfonamide (PFOSA; 0.07, 95% CI: 0.01-0.15) were significantly associated with higher CRH among white women. Results suggest complex relationships between prenatal PFAS exposure and stress response biomarkers.

## **S02.04.08. Inflammation Differentiated from Oxidative Stress in Relation to Environmental Phthalate Exposure: Evidence from Human and Animal Studies**

Kelly Ferguson

**Abstract:** Exposure to phthalates has been linked to many adverse birth outcomes including preterm birth and preeclampsia. One mechanism behind these associations may be oxidative stress, which is best estimated using biomarkers such as 8-iso-prostaglandin F<sub>2</sub>α(8-iso-PGF<sub>2</sub>α). Previously observed associations with 8-iso-PGF<sub>2</sub>α may be confounded due to simultaneous generation of this marker by an inflammation-driven mechanism. In this study, we reexamined the association between phthalate exposure and elevated oxidative stress using the ratio between 8-iso-PGF<sub>2</sub>α and PGF<sub>2</sub>α, which allows for the quantitative distinction of the two sources of 8-iso-PGF<sub>2</sub>α, i.e., oxidative stress or inflammation, and thus clarifies the true mechanism of the association. We investigated the association between phthalate metabolites and oxidative stress vs. inflammation in the Infant Development and the Environment Study. In 761 urine specimens collected during the 3rd trimester we analyzed phthalate metabolites as well 8-iso-PGF<sub>2</sub>α and PGF<sub>2</sub>α using mass spectrometry. Most phthalates were associated with increased oxidative stress. For example, an interquartile range difference in mono-n-butyl phthalate was associated with a 22% (95% confidence interval=14, 31) increase in the oxidative stress pathway in covariate-adjusted models. Detection of phthalate replacement metabolites such as di(isononyl)cyclohexane-1,2-dicarboxylate (DINCH) was associated with an increase in the inflammation pathway. We also examined these associations in an animal model, in which adult rats were administered di-butyl phthalate (DBP) or di-2-ethylhexyl phthalate (DEHP) and urine samples collected 7 hours after dosing were analyzed by mass spectrometry for the same biomarkers. We observed a similar increase in the oxidative stress pathway in response to DBP exposure. These findings have important implications for developing interventions to prevent adverse birth outcomes when intervening on exposure is difficult or impossible.

## **S02.04.09. Phthalate Exposure and Placental-Fetal Mechanisms of Endocrine Disruption**

Jennifer Adibi

*Jennifer J. Adibi<sup>1</sup>*

*1. Epidemiology, University of Pittsburgh Graduate School of Public Health, Pittsburgh, PA, United States.*

Abstract: Phthalate exposure in pregnancy is associated with child neurodevelopment and reproductive health. Elucidating the molecular basis for these associations in pregnancy is important 1) to establish causality and 2) to develop strategies to reduce the long-term risks to the health of the child. Our epidemiologic and in vitro experimental work has identified that the placental hormone human chorionic gonadotropin (hCG) is altered by phthalate exposures at the levels of tissue mRNA, intracellular hormone, and secreted hormones. These effects differ by sex of the fetus and by phthalate metabolite. Through collaboration with birth cohort studies, we have moved to a longitudinal framework and identified associations between circulating levels of hCG in early pregnancy and the size of the genitalia at birth and masculinized and feminized play behavior at 2.5 years of age. These endpoints are indicators of fetal sex differentiation. To link the two sets of findings, we applied interaction and mediation analyses, and the 4-way decomposition of these effects to better understand the role of the placenta as a putative modifier vs. a mediator of phthalate toxicity. A review of the literature has revealed that hCG regulates maternal thyroid hormone homeostasis in early pregnancy. Thyroid hormone homeostasis is also hypothesized to be perturbed by phthalates, and may act as a critical mechanistic link between exposure and developmental outcomes. Finally, we will present a pilot analysis of early pregnancy phthalates, placental hCG, and thyroid hormone levels (thyroid stimulating hormone, free thyroxine) in relation to endpoints in the children: birth size, anogenital distance, play behavior at 2.5 years, and infant cognition. Taken together, these findings have the potential to grant insight into molecular fluctuations in early pregnancy that can be measured in real time and used to identify environmental risks to the fetus and the health of the future child.

## **S02.04.10. Bisphenols and Placental Trophoblast Dysfunction**

Almudena Veiga-Lopez

*Almudena Veiga-Lopez<sup>1</sup>*

*1. Michigan State University, East Lansing, MI, United States.*

Abstract: During pregnancy, women in the U.S. are exposed to more than 60 chemicals at any given time. Specifically, exposure to bisphenolic chemicals during pregnancy occurs in >90% of pregnancies and bisphenolic chemicals can cross the placental barrier reaching fetal circulation. Bisphenol A (BPA) is the leading bisphenol in exposure prevalence followed by bisphenol S (BPS). On the other hand, during pregnancy, both the fetus and the placenta are targets of chemicals that can act as endocrine disruptors (EDCs), such as bisphenols. Given the above, our laboratory is interested in understanding whether BPA and/or BPS can affect placental function and fetal growth. Studies thus far have used in vitro approaches to investigate the effects of BPA on placental invasion, transporter expression, and steroidogenesis. In our laboratory, and using a large animal model, we have first characterized internal dose exposure in the fetal compartment for both bisphenols. Additionally, our latest work has demonstrated that gestational exposure to the emerging bisphenol BPS, but not BPA, can impair placental endocrine function pointing specifically to a dysregulation in the fusogenic trophoblast signaling pathway. These findings highlight the intrinsic differences among bisphenolic chemicals and the need to evaluate the safety of BPA analogues during vulnerable windows of development.

Abstract: The purpose of this short overview is to introduce some subjects of intense discussion during the writing of the NAS risk assessment document--"Using 21st Century Science to Improve Risk-Related Evaluations" relating to the contributions and causal reasoning in sciences contributing to risk assessment. Specifically, for environmental epidemiologic the panel discussed the use of new methods and data streams - from omics to geographic information systems and medical big data - for the purposes of risk assessment and the development of effective public health policies. The science panel summarized as advantage and challenges of epidemiology its inherently interdisciplinary nature, its struggle with the increasing complexity of scientific inquiry; and demands to integrate new knowledge from basic, clinical, and population sciences into a communicable story that can be used for policy setting and regulations.

## **S02.04.12. Systematic Review and Evidence Integration in the IARC Monographs**

Kurt Straif

*Kurt Straif<sup>1</sup>*

*1. Evidence Synthesis and Classification , International Agency for Research on Cancer , Lyon, France.*

Abstract: The IARC Monographs identify causes of cancer in the human environment, including chemicals, mixtures, personal habits, biological and physical agents. Since its inception in 1971 the Monographs programme has evaluated more than 1000 agents, with more than 100 classified as carcinogenic to humans and almost 400 as probably or possibly carcinogenic to humans. International Working Groups of experts evaluate human, animal and mechanistic evidence and reach a consensus evaluation of carcinogenicity. First, human and animal cancer data are evaluated separately, with the strength of the evidence for causation being categorised as Sufficient, Limited, Inadequate, or Suggesting lack of carcinogenicity. For the overall evaluation of carcinogenicity, the Working Group considers all streams of evidence and assigns agents to one of 5 groups: 1 Carcinogenic to Humans; 2A Probably carcinogenic to humans; 2B Possibly carcinogenic to humans; 3 Not classifiable as to carcinogenicity to humans, or 4 Probably not carcinogenic to humans. Strong mechanistic evidence can be invoked to upgrade or downgrade an evaluation. The Monographs' evaluations constitute hazard identification, but the Preamble provides the scope for characterising risk quantitatively. The presentation will focus on systematic review and evidence integration, and the principles that guide evidence integration within and across different streams of evidence. The discussion will be very timely to feed into the planned amendment of the Preamble in November 2018.

### **S02.04.13. Evidence--Law vs Science**

Dale Hattis

*Dale Hattis<sup>1</sup>*

*1. George Perkins Marsh Institute, Clark University, Arlington, MA, United States.*

Abstract: What counts as "evidence" in science is very different from the concept associated with the same word in law. In science, "evidence" is typically some set of observations accompanied by well-grounded theory relating those observations to some proposition. By contrast, in law, "evidence" is typically the testimony of someone in a position to know saying that a proposition is so. Think of eye-witness testimony in a murder trial, or a photograph of the alleged murder, backed up by a witness attesting to what the photo is, how and when it was taken and other relevant details. This paper explores the history of how these divergent meanings developed, and implications for how the different ideas of evidence might change in the future in the light of emerging technology and emerging scientific understanding.

## **S02.04.14. Careful-Causal Reasoning for Human Health: Paradigms, Argumentation and Perspectives from Environmental Epidemiology, Toxicology & Risk Communication**

Erik Lebret

*Erik Lebret<sup>1</sup>, Theo Vermeire<sup>2</sup>, Aldert Piersma<sup>1</sup>, Danielle Timmermans<sup>3</sup>*

- 1. RIVM / IRAS-UU, Bilthoven, Netherlands.*
- 2. RIVM, Bilthoven, Netherlands.*
- 3. RIVM - VU EMGO, Bilthoven, Netherlands.*

**Abstract:** Toxicologists and epidemiologists frequently need to work together to address environmental health issues. While many experts enjoy such inter-disciplinary interaction, many also acknowledge frustration in the process. At RIVM, epidemiologists and toxicologists are exploring the underlying cultures, issues and reasons behind such frustrations to improve the quality in content and process of their joint risk assessments. Identified differences include (in addition to many semantic differences) paradigm differences with respect to the assumption of a 'single sufficient cause' in experimental toxicology versus the assumption of a complex of 'multiple component causes' in epidemiology. The 'single sufficient cause' approach leads to the necessity to use very high exposures/dosages to establish effects in toxicological experiment. This in turn necessitates extrapolation to the much lower exposures in the human population and questions the relevance of the information in the context of 'multiple component causes'. Several 'allergies' about terminology and practice in the other discipline were identified which diminish or even disqualify the relevance of studies from the other discipline: These include the use of 'risk factor' and 'relative risk' and the practice of 'imputation of missing values' in epidemiology ('making up data' is considered misconduct in toxicology). Another allergy relates to the low rate of reproduction of studies and reproducibility of results in experimental toxicology and the practice of interpreting the exceedance of a toxicology based health standard, using 'safety factors' put on NOAELs from animal studies as an indication for adverse health outcomes in the human population. We will discuss the broader results from our analyses of causal reasoning about health risks in the population and (hidden) arguments used. In addition, we will address 'mental models' of lay people in response to risk communication from toxicology and epidemiology.

## **S02.04.15. Lessons from the Law**

Raymond Neutra

*Raymond R. Neutra<sup>1</sup>*

*1. Div. Env. and Occup. Disease Control, CA Dept of Public Health (Retired), Pacific Grove, CA, United States.*

Abstract: In the early 20th century, law professor JH Wigmore (1) proposed a procedure for graphically presenting an influence diagram linking pieces of direct and ancillary evidence and resulting assertions to warrant a final verdict. Twenty years ago, Kadane and Schum (2) took this further by showing how similar computerized influence diagrams with assertions linked by elicited likelihoods and computed relative likelihoods, could reveal the most sensitive assumptions in a legal argument. As earlier pointed out by Toulmin and Wigmore, moving from facts to assertions requires the endorsement of "generalities" to warrant the assertions and that ancillary evidence is needed to back these generalities. A body of evidence brought to trial is not comprehensive, if evidence has been excluded that: is known to be uncorrelated with the evidence already at hand and known to have potential probative value sufficient to reverse a verdict. Using Bayes' Theorem and by specifying the odds of guilt associated with "presumption of innocence" and "guilt beyond a reasonable doubt," they could define the relative likelihood conveyed by the overall evidence needed to reach that standard of proof. They applied this to the 359 pieces of evidence of the famous Sacco and Vanzetti case. I will argue that the Kadane and Schum approach may be helpful in guiding how epidemiologic and non-epidemiologic evidence should be combined to develop: A binary "verdict" of causation, assign an ordinal "convincingness rank" or an epistemic probability of causation. Any of these products of causal inference could be handed over for regulatory action. Only the last could be used to carry out a quantitative decision analysis. Brains and duty ethics may prefer verdicts or ranks.

Abstract: The combination of population growth in areas of mixed (residential, commercial, and industrial) land use along U.S. waterfronts and the increasing frequency of devastating hurricanes and storm surges, has led to community fears of widespread toxic chemical contamination resulting from accidental industrial or small business releases, particularly in the aftermath of an extreme weather event, such as a hurricane. Industrial waterfront communities, which are frequently environmental justice communities, contain numerous toxic chemical sources located in close proximity to residential housing, schools, daycare centers, playgrounds, and healthcare centers. In this presentation, the public health problem posed by "fugitive" chemicals, or previously confined chemicals dislodged by floodwater inundation, will be described. Recent examples of fugitive chemical releases and their potential physical and mental health risks will be presented. Approaches to characterize community exposure to fugitive chemicals, as well as opportunities to minimize exposure, will be discussed. The presentation will include a discussion of populations that may be particularly vulnerable to the health risks from fugitive chemicals, as well as an overview of populations to engage with when confronting this problem. Finally, gaps in the literature and opportunities for further research on the public health consequences of fugitive chemicals will be highlighted.

## **S02.04.17. The Fugitive Chemical: Predicting Its Release, Concentration into Community Areas and Subsequent Exposure to Recovery Workers**

Juan Osorio

*Juan C. Osorio<sup>1</sup>, Christine Chaisson<sup>2</sup>, Kerry Diskin<sup>4</sup>, Eddie Bautista<sup>3</sup>, Elizabeth Yeampierre<sup>5</sup>, Ryan Chavez<sup>5</sup>, Ramya Chari<sup>4</sup>, Regina Shih<sup>4</sup>, Jaime Madrigano<sup>4</sup>, Natasha Dwyer<sup>3</sup>, Erica Meza<sup>4</sup>*

- 4. RAND Corporation, Washington D.C., DC, United States.*
- 5. UPROSE, Brooklyn, NY, United States.*

Abstract: Properly contained industrial toxic chemicals present minimal risk to adjacent residential communities until severe weather events compromise buildings and containers. Resulting chemical dislodgement and dispersion into and around residential structures present yet-to-be quantified health threats to residents and recovery workers. The partnership Grassroots Research to Action in Sunset Park (GRASP) estimated exposure and potential risks to such fugitive chemicals released into this Brooklyn neighborhood during Superstorm Sandy in 2012. Using "traditional" and "non-traditional" data sources, the community identified over 600 chemicals potentially onsite during the storm - and used GIS to map their location and potential chemical dispersion. Using 59 different chemical source points and seven different inundation scenarios, the team estimated resulting chemical concentrations at points throughout the neighborhood. GRASP estimates that recovery workers came into contact with these possible chemical residues during cleanup activities following the storm. Descriptive narrative, videos and photographs, were used to build activity profiles for exposure assessments considering multiple activity scenarios - with and without the use of protective clothing and masks. The presentation will describe data resources and methods used to inventory community-specific data, exposure assessment approaches, underlying assumptions, lessons learned, and next steps. By facilitating the co-production of knowledge through a partnership between community organizers and urban planners, risk assessment and exposure experts, this is an innovative methodology to address a public health community concern that turns research into action - building a model for other mixed-use waterfront communities.

## **S02.04.18. How Frontline Communities Can Apply the Tools of Fugitive Chemical Risk Research**

Ryan Chavez

*Ryan Chavez<sup>1</sup>*

*1. UPROSE, Brooklyn, NY, United States.*

Abstract: This presentation will highlight how the principles and practices of community based participatory research can be used to enhance chemical exposure research, disaster preparedness, and community resilience. The speaker will illustrate the practical advantages of approaching fugitive chemical exposure research by building upon and supporting existing grassroots resiliency efforts among frontline communities. This will include methods of employing both formal data and community-driven data to address local concerns around fugitive chemical exposure. Examples will be given of how to empower communities in such research efforts, produce actionable research, and devise a research framework that serves both existing research gaps and locally-driven resiliency agendas. The speaker will highlight how such efforts are currently being used in a vulnerable industrial waterfront community in Brooklyn, New York and used to strengthen and advance several community-based resiliency efforts. This will demonstrate how fugitive chemical exposure research can be customized to reflect specific community needs while contributing and informing broader research and policy frameworks at the same time.

## **S02.04.19. A Path Forward for Protecting Against Fugitive Chemicals Under Severe Weather: Community-Based Tools, Methods, and Practices for All Communities**

Jalisa Gilmore

*Jalisa Gilmore<sup>1</sup>, Jaime Madrigano<sup>2</sup>, Juan Camilo Osorio<sup>3</sup>, Eddie Bautista<sup>1</sup>, Ryan Chavez<sup>4</sup>, Elizabeth Yeampierre<sup>4</sup>, Christine Chaisson<sup>5</sup>, Erica Meza<sup>2</sup>, Regina Shih<sup>2</sup>, Ramya Chari<sup>2</sup>*

- 3. Pratt Institute & Massachusetts Institute of Technology, Cambridge, MA, United States.*
- 4. UPROSE, Brooklyn, NY, United States.*
- 5. The LifeLine Group, Annandale, VA, United States.*

Abstract: This presentation will focus on the tools and approaches that communities can use to conduct a fugitive chemical exposure assessment to build community resilience in the event of severe weather such as a major coastal storm. Lessons learned from the partnership of exposure assessment scientists and community leaders will be highlighted and the generalization of these approaches for other waterfront mixed-use communities. The approach presented in previous parts of this Session is being employed to address the threat of fugitive chemicals from chemically intense businesses (auto shops in this case study) closely integrated into the residential geography of Brooklyn. This situation is common to communities throughout the nation. Exposure and risk are assessed for nearby residents potentially exposed to fugitive chemicals remaining after storm cleanup. This empowers communities to undertake effective actions for risk avoidance, risk mitigation and/or response to existing health threats. Local industrial businesses are often the economic heart of the neighborhood, and can engage with this work to help develop "best management practices" for resilient planning and development. Other uses of the exposure and risk assessments, including training for responders and residents doing recovery work, creation of materials for frontline health professionals, and guidance for future environmental monitoring after a storm event, are also described. The presenter will focus on common resources that can be accessed across communities, as well as how to customize the implementation to individual needs and vulnerabilities of local communities. Finally, suggestions for future research and policy implementation will be proposed.

## **S02.04.20. Panel Discussion on Preparing Working Waterfront Communities to Minimize Fugitive Chemical Threats**

Christine Chaisson

*Christine Chaisson*<sup>1</sup>

*1. The LifeLine Group, Annandale, VA, United States.*

Abstract: Working waterfront communities on rivers, lakes, bays and oceans face the threats of devastating water incursions and release of chemicals used, stored or transported through the area. When properly stored, the toxic chemicals pose little threat to workers and nearby residents, but when released into the storm waters, acute and long-term health hazards become a concern for first responders, recovery workers and the returning residents. Communities working with the waterfront and integrated industries/businesses and with exposure assessment scientists can focus action toward efficacious practices to reduce the threats and efficient methods to mitigate potential exposures. Important factors contributing to success of such undertakings depend on community/science partnership, access to local databases on chemically intense sites, exposure assessment methodologies and resources, relevant risk assessments for front line health providers, and effective community organization for action. The panel will discuss tested processes on these factors, based on the experience of past and ongoing research, avenues for expansion with disciplines that have not yet been fully incorporated into the approach, including epidemiology and health impact assessment, and the practicality of application to other working waterfront communities.

## S02.04E. Identifying Sources and Health Effects of Phenolic Consumer Product Chemicals: Product Use, Biomonitoring, and Time Trends

### S02.04.21. Maternal and Infant Exposure to Parabens, Phthalates and Phenols and the Use of Personal Care Products

Tye Arbuckle

*Mandy Fisher<sup>1</sup>, Tye Arbuckle<sup>1</sup>, Susan MacPherson<sup>1</sup>, Mark Feeley<sup>2</sup>, Joseph M. Braun<sup>6</sup>, Russ Hauser<sup>3</sup>, Mark Walker<sup>4</sup>, Ranjeeta Mallick<sup>4</sup>, René Bérubé<sup>5</sup>*

- 6. Department of Epidemiology, Brown University, Providence, RI, United States.*

Abstract: Parabens, phthalates and phenols are found in a large range of personal care products and food and beverage packaging, providing the opportunity for people to be exposed on a daily basis. In 2009–2010, 80 pregnant women from Ottawa participated in the Plastics and Personal-Care Product Use in Pregnancy (P4) Study. In early pregnancy women were asked to collect multiple urine samples over 24 h on weekday and again on a weekend day, one spot urine sample in the 2nd and 3rd trimester, and again 3 months after the baby was born. Infant urine was collected shortly after birth and again 3 months later along with breast milk. We measured levels of phthalates, parabens and phenols in maternal and infant urine samples, as well as breast milk. Women kept a diary during these time periods describing the personal care product use and ingestion of packaged food. We used this information to look at associations of products used and food packaging uses with chemical concentrations in urine and breast milk. The use of some products such as lotions, shampoo, conditioner, or cosmetics in the past day was associated with higher urinary levels of parabens and some phthalates. Our data also showed higher concentrations of chemicals in urine if the product was used in the past 6 hrs. Women who used a high number of products in the past 24 h had much higher paraben concentrations (>100%) than women who were categorized as low product users. Increased breast milk paraben concentrations were also associated with use of some personal care products (skin cleansers, make up). Plastic wrap, on food consumed in the past 24 h, was associated with higher phthalate metabolites. This study suggests that pregnant women and their infants have the potential to be exposed to multiple phthalates and parabens.

## **S02.04.22. Crowdsourced Biomonitoring in a Population of Concerned Consumers Using Detox Me Action Kit**

Robin Dodson

*Robin E. Dodson<sup>1</sup>, Katherine Boronow<sup>1</sup>, Herbert Susmann<sup>1</sup>, Kathryn Rodgers<sup>1</sup>, Julia Brody<sup>1</sup>, Ruthann Rudel<sup>1</sup>*

*1. Silent Spring Institute, Newton, MA, United States.*

**Abstract:** We sought to identify sources of twelve environmental phenols in a population highly motivated to learn about their personal chemical exposures. Over 300 people, most of whom were already connected to an environmental health network, signed up for Detox Me Action Kit as part of an online crowdfunding campaign in 2017. To our knowledge this is the first biomonitoring cohort to use this recruitment strategy. Participants collected two urine samples at home and completed an online questionnaire about exposure-related behaviors. Samples were returned frozen via overnight mail, and then composited and analyzed for parabens, bisphenols, chlorinated phenols, antimicrobials, and a UV filter. Participants received their personal exposure results as an interactive web-report. Over half the participants who completed the questionnaire reported avoiding products containing BPA, triclosan, and parabens, and measured urinary concentrations were generally lower than those reported in the National Health and Nutrition Examination Survey (NHANES). These results suggest that participants were already aware of environmental chemicals and taking steps to reduce exposures. However, intentions to avoid ingredients did not always translate to dependable behavior or to lower exposure levels. After checking the labels of their products, over a quarter of the 112 female participants who reported avoiding products containing parabens found that they used at least one personal care product where parabens was a listed ingredient. In the case of bisphenols, while participants had lower levels of the widely-scrutinized chemical BPA-in line with self-reported intentions-levels of BPF in our cohort were higher compared to levels from the 2013-2014 NHANES cycle. In this example of regrettable substitution, manufacturers may be substituting closely-related chemicals in "BPA-free" products, or in products more broadly. We explored these and other relationships in this cohort of engaged participants.

## **S02.04.23. German Environmental Specimen Bank (ESB): Time Trends of Paraben Exposure**

Marike Kolossa-Gehring

*Marike Kolossa-Gehring<sup>1</sup>, Rebecca Moos<sup>2</sup>, Till Weber<sup>1</sup>, Maria R  ther<sup>1</sup>, Andr   Conrad<sup>1</sup>, Maria Schmied-Tobies<sup>1</sup>, Thomas Br  ning<sup>2</sup>, Holger M. Koch<sup>2</sup>*

*1. German Environment Agency (UBA), Berlin, Germany.*

*2. Institute for Prevention and Occupational Medicine of the German Social Accident Insurance, Institute of the Ruhr-Universit  t Bochum (IPA), Bochum, Germany.*

Abstract: Parabens are used as preservatives e.g. in cosmetics and body care products. They have allergenic and estrogenic properties. According to the European Scientific Committee on Consumer Products (SCCP) the toxicological data available for isopropyl-, isobutyl-, pentyl-, benzyl- and phenyl-paraben do not allow for the assessment of their health impact. Therefore, since 2014, these parabens are prohibited in cosmetic products in Europe (Commission Regulation (EU) No 358/2011): For n-propyl- and n-butyl-parabene the maximum percentage was reduced to 0.19% (0.14% as acid) for each compound. Internal exposure time trends for young adults aged 20 to 29 years were analyzed in 24 h-urine samples collected by the ESB for 6 parabens (methyl-, ethyl-, iso-propyl, n-propyl, iso-butyl, and n-butyl-paraben), covering the period from 1995 to 2017. Parabens were determined after enzymatic hydrolysis via HPLC-MS/MS. The limit of quantification (LOQ) was 0.5 µg/L. In 1995 10% of the samples contained isobutyl-paraben levels above LOQ. As a maximum, a fraction of 30% was observed in 2007 and 2008. In 2017 it was found in none of the samples. The fraction of levels at or above LOQ for n-butyl-paraben decreased from 27% in 1995 to 5% in 2017 (2004: 53 %). Although the use of ethyl-paraben had been classified as acceptable by the SCCS, exposure slightly decreased: The fraction of levels at or above LOQ decreased from 85% in 1995 to 67% in 2017. Methyl-paraben was detected in all samples analysed. Apart from decreasing detection rates urinary concentrations started to drop considerably in recent years for all parabens. For further elucidating the trend, similar studies in other European countries are warranted. The decline in exposure can be considered a positive result from a precautionary standpoint. However, health based guidance values are needed for substantiated evaluation of human exposure levels.

## **S02.04.24. Racial/Ethnic Variations in Personal and Home Product Use in Pregnant Women**

Tamarra James-Todd

*Marissa Grenon<sup>1</sup>, Andrea Bellavia<sup>1</sup>, David Cantonwine<sup>2</sup>, Ellen Seely<sup>2</sup>, Thomas McElrath<sup>2</sup>, Tamarra James-Todd<sup>1</sup>*

*1. Environmental Health, Harvard T.H. Chan School of Public Health, Boston, MA, United States.*

*2. Brigham and Women's Hospital/Harvard Medical School, Boston, MA, United States.*

**Abstract:** Background: Pregnancy exposure to endocrine-disrupting chemicals (EDCs) varies across racial/ethnic groups, which could increase the risk of certain pregnancy complications and adverse reproductive health outcomes in disadvantaged populations. Identification of modifiable sources of EDCs that are unequally distributed by race/ethnicity is required to design effective public health interventions. Therefore, we evaluated differences in product use associated with EDC exposure in a diverse pregnancy cohort. Methods: We included a total of 437 women from the LIFECODES pregnancy cohort study (Boston, MA) who completed a self-reported questionnaire in the 1st and/or 2nd trimester (median 9.9 and 26 weeks gestation, respectively). Race/ethnicity was categorized as: White, Black, Asian, Hispanic, Other. The use of 19 products (13 personal care, 6 home) within 48 hours of the prenatal visit was reported. We calculated the proportion of each product use, as well as the total number of products used by racial/ethnic group. We also evaluated change in product use between the two time periods. Results: Compared to Asian and Black women, white and Hispanic reported a significantly higher use of total products in the 1st trimester (Asians: 6, 95% CI:5.5,7.4; Black: 7, 95% CI:6.2,7.8; white: 8, 95% CI:7.9,8.5; Hispanic: 9, 95% CI:8.2,9.4). Differences were mainly driven by higher use of personal care products and remained similar in the 2nd trimester. A significant reduction over time in total, personal care, and home products used was observed only among Hispanic women (-1.4, 95% CI:-1.9,-0.9; -0.8, 95% CI:-1.3,-0.3; -0.6, 95% CI:-1.1,-0.2), respectively). Conclusions: In a pregnancy cohort, we observed significant racial/ethnic differences in use of personal care and home products known to be sources of EDCs. Future studies should investigate how these usage patterns could contribute to racial/ethnic disparities in reproductive outcomes known to be associated with EDCs.

## **S02.04.25. Associations of Prenatal Exposure to Triclosan and Benzophenone-3 with Visual Recognition Memory in 7.5-Month-Old Infants**

Kelsey Dzwilewski

*Kelsey Dzwilewski<sup>1</sup>, Mariya Yanovskaya<sup>2</sup>, Andrea Aguiar<sup>3</sup>, Antonia Calafat<sup>4</sup>, Xiaoyun Ye<sup>4</sup>, Susan A. Korrick<sup>5</sup>, Susan L. Schantz<sup>3</sup>*

Abstract: Triclosan (TCS) is used in personal care products as an antimicrobial agent and benzophenone-3 (BP3) is used in personal care products and plastics as an ultraviolet absorber. Due to their endocrine disrupting properties, prenatal exposure to these chemicals may affect brain development, but little is known about their effect on infant cognition. Prenatal exposure to TCS and BP3 and visual recognition memory (measured by novelty preference) were assessed in 177 7.5-month-old infants participating in a prospective study in Illinois, USA. Study mothers were mostly white (86%), with 88% having at least a college education and 75% a household income above \$60,000. In a pool of five first morning urine samples collected across pregnancy, we quantified (median[IQR]) TCS (14.1[63.1] µg/L) and BP3 (118.6[273.0] µg/L). Infrared eye tracking recorded infant looking time at a trial with two identical faces followed by trials in which the familiar face was paired with a novel face. General linear models were used to assess associations of each exposure biomarker (adjusted for urine specific gravity) with novelty preference (percent time looking at the novel face) adjusted for infant age, gestational age, birth weight, sex, assessment condition, household income, and maternal IQ and education. There were no associations of TCS or BP3 with novelty preference and no sex differences in associations. Each IQR increase in TCS was associated with a 0.10% decrease (95% CI: -0.49,0.29) in novelty preference, while each IQR increase in BP3 was associated with a 0.04% increase (95% CI: -0.38,0.47). Generalized additive models showed no evidence of nonlinear associations of either TCS or BP3 with novelty preference. This preliminary analysis found no evidence associating maternal prenatal urinary TCS or BP3 with infants' recognition memory at 7.5 months, but the results need to be confirmed in a larger sample. ## S02.04F. Strengthening Exposure Assessment in Environmental Epidemiology: Problem Identification and Suggestions for Path Forward

### **S02.04.26. Lessons Learned from Trying to Set Guidance Values Using Human Studies**

Carol Burns

*Carol Burns<sup>1</sup>*

*1. Epidemiology, Burns Epidemiology Consulting, Sanford, MI, United States.*

Abstract: The research focus for occupational epidemiologists is safety. How can our study subjects work safely? Guidance values are established to protect employees and the general population(s). Examples of these environmental "exposures" can include uneven surfaces, physical exertion, repetition, temperature extremes, and contact with a chemical. Regulatory bodies use data from multiple disciplines to set a number, a guidance value, to inform protective practices and legal uses. Epidemiology studies, while well suited to evaluate human health and contribute to this process, often fall short in this risk assessment process. Several observations will be discussed. First, qualitative estimates such as low vs. high, and regression coefficients are not designed to test whether a unit value is protective. Second, exposure estimates are rarely harmonized across epidemiology studies, (i.e. using the same categories for low vs. high), or across disciplines (i.e. using dose in mg/kg/day vs. concentration in ug/l). Lastly, recommendations to improve the quality, reliability and validity of exposure data for risk assessment have been promulgated but not embraced by the epidemiology community due to feasibility, as one example. Before making additional recommendations, we first need to identify and resolve barriers to be successful in changing the status quo.

## **S02.04.27. Integration of Exposure Science and Epidemiology in Environmental Research: Challenges and Strengths in Using Meta-Analyses to Quantify Non-Occupational Pesticide Exposure Intensity**

Nicole Deziel

*Nicole Deziel*<sup>1</sup>

*1. Environmental Health Sciences, Yale School of Public Health, New Haven, CT, United States.*

**Abstract:** Meta-analysis is a useful tool for synthesizing exposure data across different studies. An example is the application of meta-regression models to develop weighting factors in a quantitative, active ingredient-specific algorithm for cumulative non-occupational pesticide exposure intensity for spouses of farmers applying pesticides. The algorithm addressed three exposure pathways: take-home, agricultural drift, and residential pesticide use. The meta-analysis process presented several challenges and strengths and illuminated some of the differences across the literature. **Challenges:** First, although biological monitoring is a more direct exposure assessment method, it was necessary to rely on studies measuring pesticides in house dust as an exposure surrogate, because house dust represents a time frame more appropriate for the chronic diseases of interest, and detection rates and variability in reported biomarker concentrations were low. Second, the magnitude of pathway effects may have been overestimated because studies observing no association between house dust pesticide levels and a specific pathway often did not report summary statistics and could not be included in the meta-regression. Third, though inclusion of more detailed information may have yielded better predictions with dust pesticide concentrations, the number of studies presenting similar additional information was in some cases too sparse to model. **Strengths:** The meta-analysis framework provided an opportunity to quantify and synthesize relative differences in pesticide exposure intensity from different pathways across studies of different active ingredients in different regions and using different methodologies. Meta-regression models can be updated when new data become available. Meta-regression results can inform the development of data-driven environmental exposure categorizations for epidemiologic studies.

## **S02.04.28. Health Risk Assessment: The Need of Study Design Improvement to Accommodate Individual Susceptibilities**

Josino Moreira

*Josino C. Moreira<sup>1</sup>*

*1. National School of Public Health, Oswaldo Cruz Foundation, Rio de Janeiro, Rio de Janeiro, Brazil.*

"Abstract: Scientific and technologic advances and still existing knowledge gaps have been identified in recent exposure and risk evaluation reports. New tools for evaluating and preventing negative impacts of unhealthy environments on human health, i.e. advances in computer sciences and omic techniques, promote better integration between exposure sciences and environmental epidemiology. The National Academies of Sciences, Engineering and Medicine states: "a primary objective for improving exposure science is to build confidence in exposure estimates used to support risk-based decision-making by enhancing quality, expanding coverage, and reducing uncertainty"", indicating that confidence in exposure estimates depends on data quality and risk estimation methodology accuracy. Unfortunately, no Brazilian guidelines exist, and we apply those proposed by USEPA, ATSDR, WHO or the EC. Even standards used for comparisons are determined abroad. As phenotype is linked to the environment and is regional, we ask: Are we really assessing risk for Brazilians? In fact, individual heterogeneity (genetic characteristics, health status, age, gender, stress, living environment) may influence both exposure and disease, e.g. Amazon communities ingest high mercury levels through fish but do not show intoxication signs by WHO standards, and significant discrepancies between studies in the area are noted, demonstrating the need for standardized approaches. Even under risk management policies, unexpected toxicity and adverse events may occur, often in hypersensitive individuals or small, undetected, susceptible groups. As both intrinsic and extrinsic factors determine individual susceptibility they should be incorporated in risk assessment protocols, and novel analytical approaches are required in this regard. Thus, incorporating population susceptibility measurements into risk assessment is essential to address these particularities and improve risk management in the age of precision medicine. "

## **S02.04.29. Strengths and Limitations: Integration of Exposure Sciences and Epidemiology in Health Risk Assessment of Environmental Contaminants**

Roel Vermeulen

*Roel Vermeulen<sup>1</sup>*

*1. IRAS, Utrecht University, Utrecht, Netherlands.*

Abstract: Risk assessment of environmental contaminants is based on an integrated evaluation of in-vitro, in-vivo and human data. More than a 100.000 new chemicals have been synthesized in the last 5 decades. A few thousand of these have become wide-spread in the environment. Of these many have not undergone testing for safety or toxicity as thorough pre-market testing has only been institutionalized in the last decade in some regions of the world. Additionally, toxicity tests are not a 100% predictive for adverse human health effects in itself. Therefore, environmental epidemiology plays a key role in post-market research and can play a role in both hazard and risk characterization. As more epidemiological studies have become available in more recent years their use in risk assessment has increased. For example, the Dutch Health Council committee on cancer risk values has increasingly used epidemiological studies to set such limits (increasing from 0% in 1995 to 25% in 2013 of all evaluations in that time period). However, the utility of environmental epidemiology in risk assessment depends strongly on the quality of the exposure assessment. For example, in a hazard evaluation we conducted for electromagnetic low field (ELF-MF) exposure and risk of Amyotrophic Lateral Sclerosis (ALS), studies that had limitations in the exposure assessment did not show a clear association while studies that had better exposure assessment showed a clear increased risk between ELF-MF exposure and ALS. Similarly, in a risk evaluation of asbestos exposure and lung cancer, we observed a difference in risk per unit of exposure of a factor of 4 between the best to all studies. These two examples are indicative of the importance of good quality exposure assessment in epidemiological studies. In order to facilitate the transparent use of epidemiological studies in risk assessment evaluation tools for study design (e.g. ROBINS-E) with a strong focus on exposure assessment quality should be used.

## S02.04G. The Global Burden Estimates of the Impacts of Air Pollution: Methods, Innovative Applications, and WHO Results

### **S02.04.31. Assessing the Recent Estimates of the Global Burden of Disease for Ambient Air Pollution: Methodological Changes and Implications for Low- and Middle-Income Countries**

Joseph Spadaro

- 6. World Bank, Washington, United States Minor Outlying Islands.*

**Abstract:** The Global Burden of Disease (GBD) is a comparative assessment of the health impact of the major and well-established risk factors, including ambient air pollution (AAP), assessed by concentrations of PM<sub>2.5</sub> (particles less than 2.5 microns) and ozone. Over the last two decades, major improvements have emerged for two important inputs in the methodology for estimating the impacts of PM<sub>2.5</sub>: The assessment of global exposure to PM<sub>2.5</sub> and the development of integrated exposure risk models (IERS) that relate the entire range of exposures to PM<sub>2.5</sub> to cause-specific mortality risks. As a result, the estimated annual mortality attributed to AAP increased from less than 1 million in 2000 to roughly 3 million for GBD in years 2010 and 2013, and to 4.2 million for GBD 2015. However, the magnitude of the recent change and uncertainty regarding its rationale have resulted, in some cases, in skepticism and reduced confidence in the overall estimates. To understand the underlying reasons for the change in mortality, we examined the estimates for the years 2013 and 2015 to determine the quantitative implications of alternative model input assumptions. We calculated that the year 2013 estimates increased by 8% after applying the updated exposure methods used in GBD 2015, and increased by 23% with the application of the updated IERS from GBD 2015. The application of both upgraded methodologies together increased the GBD 2013 estimates by 35% or about one million deaths. We also determined the impact of changes in demographics and assumptions about the threshold concentration. Since the global estimates of air pollution-related deaths will continue to change over time, a clear documentation of the modifications in the methodology and their impacts is necessary. In addition, there is need for additional monitoring and epidemiological studies to reduce uncertainties in the estimates for low- and medium-income countries.

## **S02.04.32. From Satellites to Burden: New Approaches to Assessing the Global Burden Associated with Ambient Air Pollution**

Gavin Shaddick

*Gavin Shaddick<sup>1</sup>*

*1. University of Exeter, Exeter, United Kingdom.*

Abstract: In order to estimate the burden of disease attributable to fine particulate ambient air pollution, country-level estimates of population-level exposures, together with associated measures of uncertainty, are required. The primary source of information for estimating exposures has been measurements from ground monitoring networks but, although coverage is increasing, there remain regions in which monitoring is limited. Ground monitoring data therefore needs to be supplemented with information from other sources, such as satellite retrievals of aerosol optical depth and chemical transport models. A hierarchical modelling approach for integrating data from multiple sources is proposed allowing spatially-varying relationships between ground measurements and other factors that estimate air quality. Temporal trends are modelled by allowing relationships to change, smoothly, over time. Set within a Bayesian framework, the resulting Data Integration Model for Air Quality (DIMAQ) is used to estimate exposures on a high-resolution grid covering the entire world. For each grid-cell, a full posterior distribution (of exposures) is produced, allowing point estimates (e.g. means, medians), measures of uncertainty (e.g. credible intervals) and exceedance probabilities (e.g. probability of being over guidelines) to be calculated. Bayesian analysis on this scale can be computationally challenging and here approximate Bayesian inference is performed using Integrated Nested Laplace Approximations (INLA). Estimated exposures from the model, produced on a high-resolution grid (10km x 10km) covering the entire globe, are combined with risk estimates to produce a global assessment of exposures to PM<sub>2.5</sub> over time (2010-2016) and to estimate the associated burden of disease attributable to air pollution.

### **S02.04.33. Global Mortality and Long-Term Ambient Exposure to Fine Particulate Matter: A New Relative Risk Estimator**

Richard Burnett

*Richard Burnett<sup>1</sup>, Joseph Spadaro<sup>2</sup>*

*1. Population Studies Division, Health Canada,, Ottawa, ON, Canada.*

*2. Private consultant, Bilbao, Spain.*

**Abstract:** Exposure to ambient fine particulate matter (PM<sub>2.5</sub>) is a major global health concern, accounting for over 4 million premature deaths in 2015. This estimate is based on a mortality relative risk model that incorporates information from multiple PM<sub>2.5</sub> sources (ambient and indoor air pollution, second hand and active smoking), requiring assumptions about equivalent exposure and toxicity among sources. We relax these contentious assumptions by constructing the first PM<sub>2.5</sub>-mortality relative risk function based only on cohort studies of ambient air pollution that covers the global exposure range. We modelled the shape of the association between PM<sub>2.5</sub> and non-accidental mortality, the Global Exposure Mortality Model (GEMM), using data from 41 cohorts covering 16 countries, including recent epidemiological evidence from Asia. We restricted burden assessments to non-communicable disease plus LRI for those over the age of 25 years as this group represents almost all the causes of death in the cohorts used to estimate the GEMM associations. We also constructed GEMMs for five specific causes of death examined by the Global Burden of Disease (GBD): ischemic heart disease, stroke, chronic obstructive lung disease, lung cancer, and lower respiratory infections (LRI) to estimate global PM<sub>2.5</sub> deaths in 2015. GEMM predicts 8.9 million (95% confidence interval (CI): 7.5-10.3), a figure 30% larger than that predicted by the sum of deaths among the five specific causes (6.9, 95% CI: 4.9-8.5), and 220% larger than the risk functions used in the GBD (4.0, 95% CI: 3.3-4.8). About half of the predicted global mortality is attributed to low and lower middle-income countries, where exposure and population vulnerability is highest. These results suggest that PM<sub>2.5</sub> exposure may be related to additional causes of death than the five considered by GBD, and that incorporation of other, non-ambient, particle sources, leads to under-estimates of disease burden especially at higher concentrations.

## **S02.04.34. The World Health Organization (WHO) Global Estimates of the Impact of Air Pollution**

Sophie Gumy

*Sophie Gumy<sup>1</sup>, Heather Adair-Rohani<sup>1</sup>, Pierpaolo Mudu<sup>1</sup>, Francesco Forastiere<sup>2</sup>*

*1. WHO, Geneva, Switzerland.*

*2. Department of Epidemiology, Lazio Regional Health Service, Rome, Italy.*

Abstract: Air pollution has been identified as a global health priority in the sustainable development agenda. The World Health Organization (WHO) has responsibility for stewarding three air pollution-related indicators for monitoring progress against the Sustainable Development Goals (SDGs): in health (Goal 3) - mortality from air pollution, in cities (Goal 11) - air quality in cities, and in energy (Goal 7) - access to clean fuels and technologies. This session will present WHO updated global estimates of exposure and burden of disease from air pollution from particulate matter, which are used for SDG reporting at the global, regional and national level. These estimates are based on improved exposure estimates and integrated exposure risk models. Over the last two decades, there has been considerable improvement in two important inputs of the methodology for estimating the impacts of PM<sub>2.5</sub>: The assessment of global exposure to PM<sub>2.5</sub> using satellite data and its integration with ground measurements, and the development of integrated exposure risk models (IERs) that relate the entire range of exposures to PM<sub>2.5</sub> to cause-specific mortality risks. To date, air pollution - both ambient and household - is the biggest environmental risk to health, carrying responsibility for about one in every 8 deaths annually. Ambient (outdoor) air pollution alone kills around 4 million people each year, mainly from noncommunicable diseases. To support countries in choosing policies aiming at reducing air pollution and promoting health, WHO is further developing and refining tools to support planning for clean household energy policies (the Clean Household Energy Solutions Toolkit); to quantify the health impacts of air pollution (AirQ+ software); and to estimate the expected health impacts from policies taken by other sectors (for example, transport, waste management, and land-use planning).

## **S02.04.35. Impact Assessment at Global and Local Level Using the WHO Software AirQ+**

Pierpaolo Mudu

*Pierpaolo Mudu<sup>1</sup>*

*1. World Health Organization, Geneva, Switzerland.*

Abstract: Air pollution is the most important environmental risk factor to health and has been identified as a global health priority in the sustainable development agenda, and also by the World Health Organization (WHO). Quantifying the effects of exposure to air pollution in terms of public health has become a critical component in policy discussion. The WHO Regional Office for Europe has developed AirQ+ software within its activities on air quality and health. AirQ+ is designed to calculate the magnitude of the impacts of air pollution on health in a given population. It handles long- and short-term exposure to ambient air pollution from several pollutants and long-term exposure to household air pollution from polluting fuel use. Pollutants considered include particulate matter, nitrogen dioxide, black carbon, and ozone. AirQ+ can be used for any city, country or region to estimate: 1) How much of a particular health outcome is attributable to selected air pollutants? 2) Compared to the current scenario, what would be the change in health effects if air pollution levels changed in the future? All calculations performed by AirQ+ are based on methodologies and concentration-response functions established by epidemiological studies. The concentration - response functions used in the software are based on systematic reviews of all studies available and their meta-analysis.

O03.01A. Carbon Monoxide and Radon in Residential Buildings

**O03.01.01. A Mixed Methods Approach to Radon Health Risk Perception of Ottawa Residents**

Selim Khan

*Selim Khan<sup>1</sup>, James Gomes<sup>2</sup>, Samia Chreim<sup>3</sup>*

*1. Interdisciplinary School of Health Sciences, University of Ottawa, Ottawa, ON, Canada.*

*2. Faculty of Health Sciences, University of Ottawa, Ottawa, ON, Canada.*

*3. Telfer School of Management, University of Ottawa, Ottawa, ON, Canada.*

Abstract: Background: Canadians have reason to care for indoor air quality as they spend over 90% of their time indoors. The geographic location and old houses make Ottawa residents at risk of the high level of radon exposure. Indoor radon causes more deaths than any other environmental hazards. While 55% residents are aware of the health risk, only 6% have taken action. Objective: To understand residents' perceptions of the health risks of radon and to assess their perceived need to take action. Methods: In mixed methods approach, an online survey (N=308) with Qualtrics and semi-structured face to face qualitative interviews (N=35) were conducted with both homeowners and tenants in Ottawa. These quantified and explored residents' perception of and adaptations for the risk. Quantitative data were analyzed in SPSS and qualitative analysis was done in Atlas-Ti using a two-coder iterative content approach. Results: The majority of participants were Caucasian (77%), male (51%), homeowners (72%), and under age 65 (71%). Overall, 34% residents have some concerns about radon health risk, 12% have tested, and only 4% mitigated their homes for radon. Residents' perception of the severity of the risk, social influence, and smoking history significantly correlate with their intention to test for radon whereas synergistic risk perception with smoking predicts the perception of severity of the risk. Three themes emerged from qualitative analyses of interviews: 1) despite the gravity of radon health risks, there are minimum government programs to inform residents. 2) residents' concern about the risk and care for family welfare motivate them to take action. 3) health communication program should tap into the emotional aspect of awareness beyond the cognitive awareness. Conclusions: There are inadequate government initiatives, and the health communication messages remained ineffective. Policy should address the shared responsibility of both government and residents in tackling the issue.

### **O03.01.02. Protecting Populations from Radon in Ontario, Canada: Translating Research to Evidence-Based Public Health Practice**

Elaina MacIntyre

*Elaina MacIntyre<sup>1</sup>, Jinhee Kim<sup>1</sup>, Ray Copes<sup>1</sup>*

*1. Environmental & Occupational Health, Public Health Ontario, Toronto, ON, Canada.*

Abstract: Radon is a ubiquitous public health hazard and the second leading preventable cause of lung cancer. Public Health Ontario (PHO) has been engaged in various activities to promote local level public health action on radon since 2013. This presentation will describe how these applied research projects have resulted in effective action to understand and mitigate radon exposure in Ontario. In 2013, PHO estimated that 847 lung cancer deaths per year were attributable to radon. PHO presented these results at various meetings, and in an online infographic and interactive report to highlight findings by region and identify strategies for local level public health practitioners to address radon. In 2016, PHO partnered with Cancer Care Ontario to estimate the cancer burden of environmental hazards and identified radon as the second leading carcinogen in terms of projected future cancer cases (1,310 per year). This was followed by a 1-day event for local level public health practitioners to share strategies and lessons learned in addressing radon at the local level. In late 2017, PHO conducted an online survey to identify how radon was being addressed by local level public health. There were over 100 specific activities targeting radon in one of 4 categories: responding to public concern (28%), public education activities (43%), measurement campaigns (13%), and 'other' (16%). Between 2013 and 2016, the number of public health authorities engaged in radon activities increased 6-fold. In early 2018, a new Ontario Healthy Environments and Climate Change Guideline was released to provide direction to local health authorities on how to approach specific public health requirements around radon (implementing public awareness initiatives and mitigation strategies). This marks the first time radon has been included in official guidance for public health practitioners in Ontario, and illustrates the provincial impact of building capacity at the local level for priority health hazards.

### **003.01.03. Association of Indoor Air Pollutants and Cardiovascular Hemodynamics**

YunShan Chung

*1. Institute of Occupational Medicine and Industrial Hygiene, National Taiwan University, Taipei, Taiwan.*

*2. Department of Internal Medicine and Cardiovascular Center, National Taiwan University College of Medicine, Taipei, Taiwan.*

**Abstract:** Backgrounds: Indoor air quality has been associated with human health, however, there is limited information regarding personalized indoor air pollutants and cardiovascular hemodynamics. This study aims to investigate the concurrent real-time monitoring of indoor air quality and cardiovascular function. Methods: During July-October 2017, we recruited 40 subjects from 31 family for this study. Concurrent 24-h real-time monitoring of indoor air quality and cardiovascular hemodynamics were performed for each participant. Cardiovascular hemodynamics were measured via arterial pressure waveform by a cuff sphygmomanometer using an oscillometric BP device (DynaPulse 200M, Pulse Metric Inc., San Diego, CA). Time series analysis was applied to estimate the change of cardiovascular hemodynamics for every one unit (different scales) increase of air pollutants for 40 subjects. Results: The median (IQR) concentration of 24-hour indoor air pollutants were 28.80 (23.98)  $\mu\text{m}^3$  for PM<sub>2.5</sub>, 30.47(25.03)  $\mu\text{g}/\text{m}^3$  for PM<sub>10</sub>, 0.487(0.667)  $\mu\text{g}/\text{m}^3$  for carbon monoxide (CO), and 452.0 (295.0)  $\mu\text{g}/\text{m}^3$  for carbon dioxide (CO<sub>2</sub>). Time series analysis showed for every 1  $\mu\text{g}/\text{m}^3$  increase of indoor CO exposure, cardiovascular hemodynamics would increase 1.403(0.095-2.712) and 1.397(0.081-2.712) mmHg in concurrent and lag 1h systolic blood pressure respectively. In addition, the corresponding change of cardiac output would increase by 70 (13-127) ml and 73(14-132) ml for lag 1h and lag 4h respectively. For every 100  $\mu\text{g}/\text{m}^3$  increase in indoor CO<sub>2</sub> exposure, the concurrent and lag 1h cardiac output would increase by 24.1(4.9-43.3) ml and 31(12.8-49.2) ml respectively. Conclusion: Real-time indoor air quality monitoring of CO and CO<sub>2</sub> was strongly associated with personalized 24h cardiovascular hemodynamics.

#### **O03.01.04. Descriptive Epidemiology of Hospital Admissions Due to Carbon Monoxide Poisoning in England, between 2008 and 2015**

Aina Roca Barceló

*Aina Roca Barceló<sup>1</sup>, Fred B. Piel<sup>1</sup>, Rebecca Gosh<sup>1</sup>, Helen Crabbe<sup>2</sup>, Tony Fletcher<sup>2</sup>, Rebecca Close<sup>2</sup>, Anna Hansell<sup>1</sup>, Giovanni S. Leonardi<sup>2</sup>*

*1. UK Small Area Health Statistics Unit, MRC PHE Centre for Environment and Health, Imperial College London, London, United Kingdom.*

*2. Environmental Epidemiology Group, Public Health England, Centre for Radiation, Chemical and Environmental Hazards, Chilton, United Kingdom.*

**Abstract:** Background Data on carbon monoxide poisoning (CO<sub>p</sub>) for England and other high-income countries are relatively limited. We aimed to provide updated data on hospital admissions for intentional, accidental non-fire related (ANFR), and unknown causes of CO<sub>p</sub> in England (2008-2015). **Methods** Hospital admissions for England with a primary diagnosis of CO<sub>p</sub> were collected. Rates per 100,000 inhabitants were estimated by age group, sex, calendar-year and ethnicity, using population estimates for England, and used to analyse temporal trends with log-linear models. Changes are shown as Annual Percent Change (APC). Deprivation, defined as quintiles of the Carstairs index, and seasonal patterns were also investigated. **Results** Overall, we identified 3,686 CO<sub>p</sub> hospital admissions (58% accidental of which 89% were ANFR; 35% intentional, and 6% of unknown cause), corresponding to an average of 460 CO<sub>p</sub> admissions/year. Preliminary results show a significant decrease in the number of intentional CO<sub>p</sub> admissions in both men (APC: -9.63%, p<0.05) and women (APC: -8.03%, p<0.05) over the 8 year period; ANFR CO<sub>p</sub> admissions decreased significantly only in women (APC: -6.35%). The largest proportions of ANFR CO<sub>p</sub> cases occurred during the winter months (males: 30.8%; females: 35.5%), among the most deprived (~28%, both genders) and in patients over 80yrs (men: 1.59 OR; women: 1.38 OR). Intentional CO<sub>p</sub> was most common among men aged 30-60yrs and showed no seasonal pattern. Higher rates of ANFR and intentional CO<sub>p</sub> were found in black/black British and white/white British, respectively. **Conclusions** Nationally, this study shows a significant decrease over the study period in hospital admissions for intentional CO<sub>p</sub> in both genders, and for ANFR CO<sub>p</sub> in women. We found demographic differences, with a greater proportion of hospital admissions for ANFR CO<sub>p</sub> in women, the over 80 year olds, black/black British and highly deprived groups. The reasons for these changes are being investigated.

## O03.01B Estimating Air Pollution Exposures and Health Outcomes Associated with Wildfires

### O03.01.05. A Machine Learning Approach to Estimate Hourly Exposure to Wildfire Smoke for Urban, Rural, and Remote Population

Jiayun Yao

*Jiayun A. Yao<sup>1</sup>, Michael Brauer<sup>1</sup>, Sean Raffuse<sup>2</sup>, Sarah B. Henderson<sup>3</sup>*

*1. School of Population and Public Health, University of British Columbia, Vancouver, BC, Canada.*

*2. University of California, Davis, Davis, CA, United States.*

*3. British Columbia Centre for Disease Control, Vancouver, BC, Canada.*

Abstract: Increases in wildfire frequency and intensity have been observed over recent decades, and are expected to continue with climate change. Exposure to wildfire smoke has been associated with a wide range of acute cardiopulmonary outcomes, but most of the epidemiologic evidence is based on exposures averaged over the 24-hour period on the day of the observed outcomes. Little is known about the effects of sub-daily exposures immediately preceding acute events such as myocardial infarction, stroke, or exacerbations of chronic respiratory diseases. Thus, it remains unclear to what extent the cardiopulmonary effects of wildfire smoke can be attributed to short (i.e. hours) but extreme levels of exposure compared with longer (i.e. days) periods of cumulative exposure. One big challenge for studying sub-daily effects is the lack of spatially and temporally resolved estimates of smoke exposures. Although some deterministic air pollution models can provide sufficient resolution, they require extensive expertise and computing power, and have large uncertainty in performance. As an alternative, we developed a Random Forests machine learning approach to estimate 1-hour average population exposure to fine particulate matter during wildfire seasons from 2010 to 2015 in British Columbia, Canada, at a 5km by 5km resolution. The model used data from available air quality monitors, remotely sensed fire activity, meteorology assimilated from satellite data and modeling, as well as geographic and ecological information. The final model explained 83% of the variance in out-of-sample evaluation, with low mean fraction bias of -0.31%. This performance was sustained across years and locations. Two case studies showed a high degree of spatial and temporal agreement between model predictions and observations. This model will be useful for conducting epidemiologic studies on sub-daily exposure to wildfire smoke, as well as informing public health actions once operationalized in near-real-time.

### **O03.01.06. Cardiovascular and Cerebrovascular Emergency Department Events Related to California Wildfires in 2015**

Ana Rappold

- 1. US EPA, RTP, NC, United States.*
- 2. School of Medicine, University of California San Francisco, San Francisco, CA, United States.*
- 3. California Department of Public Health, San Francisco, CA, United States.*

**Abstract:** Fine particulate matter (PM<sub>2.5</sub>) found in smoke can exacerbate respiratory conditions; however, evidence for cardiovascular and cerebrovascular events has been inconsistent. **Methods:** We conducted a time series analysis of adult cardiovascular and cerebrovascular events for the 2015 wildfire season in 8 California Air Basins. We used estimated fire-PM<sub>2.5</sub> concentrations and satellite data from the Hazard Mapping System together with California statewide emergency department (ED) data at the ZIP code-level. Age- and gender-stratified population subsets were modeled with lags up to 5 days and models were adjusted for adjusted for seasonal trend, day of the week and heat index. **Results:** All-cause cardiovascular ED visits across all lags were elevated (RR of 1.07, 95%CI[1.05, 1.09]), as were all-cause cerebrovascular (1.13 [1.05-1.21]), and all-cause respiratory visits (1.10 [1.08,1.12]). No significant association was found for the control condition of acute appendicitis (0.93 [0.81,1.06]). Elevated individual diagnoses included ischemic heart disease (1.09 [1.05, 1.13]), heart failure (1.10 [1.06,1.14]), and dysrhythmia (1.14 [1.11,1.17]). Ischemic strokes were elevated up to 5 lag days for adults 65 years and older (1.21 [1.05, 1.37]). Dose-dependent responses were observed for fire-PM<sub>2.5</sub> and nearly all diagnosis categories, across all 5 lags. **Conclusions:** Wildfire PM<sub>2.5</sub> elevated the risk of cardiovascular and cerebrovascular ED visits. This abstract does not necessarily reflect US EPA views and policies.

### **O03.01.07. A Causal Inference Analysis of the Effect of Wildland Fire Smoke on Ambient Air Pollution Levels and the Associated Health Burden from Wildfire-Contributed PM2.5**

Alexandra Larsen

*Alexandra Larsen<sup>1</sup>, Ana G. Rappold<sup>2</sup>, Shu Yang<sup>1</sup>, Brian Reich<sup>1</sup>*

*2. Environmental Public Health Division, U.S. Environmental Protection Agency, Chapel Hill, NC, United States.*

Abstract: Wildfire smoke contains hazardous levels of fine particulate matter (PM2.5), a pollutant shown to adversely affect respiratory and cardiovascular health. Estimating PM2.5 concentrations attributable to wildfires is key to understanding the extent to which wildfires contribute to poor air quality and subsequent health burdens. This is a challenging problem since only total PM2.5 is measured at monitoring stations in the U.S., meaning we only ever observe PM2.5 from all sources (wildfire smoke, anthropogenic sources, natural non-fire sources, etc.). We propose a method for separating estimates of wildfire-contributed PM2.5 from ambient PM2.5 concentrations using a novel causal inference framework and bias-adjusted computer simulations of PM2.5 under counterfactual scenarios. The numerical PM2.5 data for this analysis is from the Community Multi-Scale Air Quality (CMAQ) Modeling System, run with and without fire emissions across the contiguous U.S. for the 2008-2012 fire seasons. To account for biases, the CMAQ output is calibrated with observed data from the U.S. Environmental Protection Agency's Federal Reference Method (FRM) PM2.5 monitoring sites for the same spatial domain and time period. We use a Bayesian model that accounts for spatial variation to estimate the effect of wildfires on PM2.5 and state assumptions under which the estimate has a valid causal interpretation. Our results include estimates of absolute, relative and cumulative contributions of wildfire smoke to PM2.5 for the contiguous U.S. Additionally, we compute the health burden associated with the PM2.5 attributable to wildfire smoke. Our results provide insight into using causal inference with numerical and spatial data, as well as a method that we extend to investigate the causal effects of wildfire smoke on public health outcomes. Disclaimer: This work does not necessarily represent EPA views or policy.

### **003.01.08. The British Columbia Asthma Prediction System (BCAPS): A Surveillance System to Forecast the Public Health Impacts of Wildfire Smoke**

Kathleen McLean

*Kathleen E. McLean<sup>1</sup>, Kathryn T. Morrison<sup>2</sup>, Jiayun A. Yao<sup>1</sup>, Gavin Shaddick<sup>3</sup>, David L. Buckeridge<sup>2</sup>, Sarah B. Henderson<sup>1</sup>*

- 1. Environmental Health Services, BC Centre for Disease Control, Vancouver, BC, Canada.*
- 2. Department of Epidemiology and Biostatistics, McGill University, Montreal, QC, Canada.*
- 3. Department of Mathematical Sciences, University of Bath, Bath, United Kingdom.*

**Abstract:** Smoke from severe wildfires during the summers of 2015 and 2017 affected most of the population of British Columbia (BC), Canada. Asthma-related health outcomes are consistently elevated when populations are exposed to wildfire smoke in BC. Timely information during smoke events is important to inform the actions of public health authorities. We developed a surveillance system using short-term wildfire smoke forecasts to predict the potential health impacts of smoke over the coming days and provide this information to public health authorities in easy-to-interpret daily reports. The BCAPS framework is modular such that different data, modelling approaches, and visualizations can be applied. We used daily fine particulate matter (PM<sub>2.5</sub>) measurements, daily counts of asthma-related population health outcomes, and PM<sub>2.5</sub> forecasts to predict and visualize smoke exposures and their health impacts across different geographic areas over the coming 48 hours. We applied BCAPS retrospectively during a 2015 smoke event using a Bayesian latent process model to forecast health outcomes. We prospectively applied BCAPS in 2017 using random forest models to predict PM<sub>2.5</sub> exposure and health outcomes. Daily PM<sub>2.5</sub> measurements ranged from 0.03 µg/m<sup>3</sup> to 301.2 µg/m<sup>3</sup> during the 2015 event and from 0.05 µg/m<sup>3</sup> to 293.8 µg/m<sup>3</sup> in 2017. Daily PM<sub>2.5</sub> and daily counts of asthma-related physician visits and medication dispensations were increased during smoky periods in 2015 and 2017. In general, BCAPS predicted the smoke-related increases in asthma outcomes with good accuracy, though performance was dependant on the performance of the smoke forecasts. In 2017 there was a marked decrease in population response to smoke towards the end of the season even though PM<sub>2.5</sub> concentrations remained high. Integrating data from multiple sources into a modular framework such as BCAPS can usefully predict the health impacts of smoke exposure in a timely manner to inform public health decision-making and action.

## O03.01C. Impacts and Evaluation of Arsenic Exposures

### **O03.01.09. Preliminary Quantitative Risk Assessment: Arsenic Exposure from Drinking Water on the Hopi Lands**

Jonathan Blohm

*1. University of Arizona, Tucson, AZ, United States.*

*2. Hopi Tribe, Kykotsmovi, AZ, United States.*

**Abstract:** Introduction: Water quality data from Native American lands in Northern Arizona is limited. The effect of long-term exposure to arsenic in drinking water may influence the development of later onset cancers and pulmonary diseases and are of concern to the Hopi Tribe. Methods: Since December of 2017, tap water and urine samples have been collected from 18 households on Hopi lands. Tap water and urine samples were evaluated for speciated arsenic concentrations by ICP-MS. Results: Of the 18 households surveyed, 50% report that their main source of water ingestion is a combination of both tap water and bottled water. Preliminary data indicate that arsenic concentrations in the tap drinking water range from 2.84 to 21.32 mg/L, with a median concentration of 14.69 mg/L. Based on these data, we performed a preliminary quantitative risk assessment on the relative risk of lung and bladder cancer from exposure to arsenic in tap water. The analysis indicated the risk of males for lung and bladder cancers to be 8.27 and 3.71 in 10<sup>6</sup>, respectively in assuming consumption of tap water exclusively. The analysis also indicated the risk of females for lung and bladder cancers to be 6.48 and 1.02 in 10<sup>6</sup>, respectively in assuming consumption of tap water exclusively. These preliminary results exceed the EPA's acceptable carcinogenic risk limit of 1 in 10<sup>6</sup>. These are only preliminary results.

**003.01.10. An Evaluation of Speciated Plasma Arsenicals as Potential Biomarkers of Arsenic Exposure and Arsenic-Associated Diabetes in Individuals Living in Zimapan and Lagunera, Mexico**

**Abstract:** Background: Exposure to inorganic arsenic (iAs) remains a public health issue. Typically, three major forms of arsenic are measured in urine as biomarkers of iAs exposure, namely, iAs, and its metabolites, monomethylated arsenic (MMAs) and dimethylated arsenic (DMAs). This study is among the first to examine speciated plasma arsenicals as biomarkers of iAs exposure and iAs-associated disease, namely, diabetes mellitus (DM). Methods: Drinking water and plasma samples were collected from participants in the Zimapan and Lagunera cohort (N = 258). The relationships between drinking water iAs and plasma arsenicals were examined using both spearman correlations and multivariable linear regression models. Multivariable linear and logistic regression models were used to estimate the mean difference (95% CI) for the relationship between plasma arsenicals and diabetes indicators and the odds ratio (95% CI) for the relationship between plasma arsenicals and DM. Results: Plasma arsenicals were associated with drinking water iAs, with spearman correlation coefficients of 0.45 for P-MMAs, 0.48 for P-DMAs and 0.41 for total arsenic (P-tAs;  $p < 0.0001$ ). After adjusting for potential confounders, there were significant associations between log-transformed plasma arsenic and log-transformed diabetes indicators. Specifically, an interquartile range (IQR) increase in P-iAs was associated with fasting plasma insulin (0.089 (95% CI: 0.025, 0.153)), insulin resistance (HOMA-IR; 0.084 (95% CI: 0.017, 0.152)), and beta cell function (HOMA-B; 0.133 (95% CI: 0.007, 0.259)). Plasma arsenicals were not associated with the odds of DM. Conclusions: Speciated plasma arsenicals were associated with drinking water iAs, suggesting that they may serve as biomarkers of iAs exposure. Increases in fasting plasma insulin, HOMA-IR, and HOMA-B in the absence of changes in glycemia, indicate that plasma arsenic may be related to subclinical changes in pancreatic beta cell function that underlie DM development.

### **003.01.11. Co-Exposure to Methylmercury and Inorganic Arsenic in Baby Rice Cereals and Rice-Containing Teething Biscuits**

Sarah Rothenberg

*3. University of South Carolina, Columbia, SC, United States.*

**Abstract:** Background: Rice is an important dietary source for methylmercury, a potent neurotoxin, and inorganic arsenic, a human carcinogen. Infants are often weaned onto rice-containing cereals. Rice baby cereals and other rice-containing products are a dietary source of inorganic arsenic; however, less is known concerning methylmercury. Methods: 48 boxes of baby foods were purchased in South Carolina (n=28), California (n=9), Ohio (n=6), New York (n=3), and Florida (n=2). Total mercury and methylmercury concentrations were measured in 36 rice baby cereals, eight rice teething biscuits, and four baby cereals manufactured with oats/wheat (n = 48). Concentrations of inorganic and organic arsenic species were determined in rice baby cereals and rice teething biscuits (n = 44/48), while total arsenic was determined in all products (n = 48). Results: All rice baby cereals and teething biscuits contained methylmercury, while inorganic arsenic concentrations in two brands of rice baby cereal (n = 12/36 boxes of rice cereal) exceeded 100 ng/g, the proposed action level from the U.S. Food and Drug Administration. Rice baby cereals and rice teething biscuits were on average 61 and 92 times higher in methylmercury, respectively, and 9.4 and 4.7 times higher in total arsenic, respectively, compared to wheat/oat baby cereals. For a 15-g serving of rice baby cereal, average methylmercury intake was 0.0092 µg/day (range: 0.0013-0.034 µg/day), while average inorganic arsenic intake was 1.3 µg/day (range: 0.37-2.3 µg/day). Conclusions: Results from this study suggest frequent ingestion of rice baby cereal and rice-containing teething biscuits will contribute to higher intake of both methylmercury and inorganic arsenic during the period when infant brains and bodies are rapidly developing. Studies concerning the cumulative impacts of methylmercury and inorganic arsenic on offspring development are warranted. Funding: NIH R21ES026412

### **O03.01.12. The Impact of Arsenic Exposure on Whole Blood DNA Methylation: An Epigenome-Wide Study of Bangladeshi Adults**

**Abstract:** Background: Arsenic exposure affects >200 million people worldwide, including ~56 million in Bangladesh. Arsenic exposure increases the risk of chronic disease, and one potential mechanism of arsenic toxicity is epigenetic dysregulation of DNA methylation. Objective: We assessed associations between arsenic exposure and genome-wide DNA methylation among 396 Bangladeshi adults participating in the Health Effects of Arsenic Longitudinal Study (HEALS), who were exposed by drinking naturally-contaminated well water. Methods: Methylation in whole blood DNA was measured at ~850,000 CpGs using the Illumina EPIC array. To assess associations between arsenic exposure and CpG methylation, we used multivariate linear regression models adjusted for covariates and surrogate variables (capturing unknown technical and biologic factors). We attempted replication and conducted a meta-analysis using an independent set of 400 exposed Bangladeshi adults with data on ~450,000 CpGs. Results: We identified nine CpGs associated with urine arsenic exposure (Bonferroni-corrected threshold  $p < 6.5 \times 10^{-8}$ ). Four of these CpGs annotated to the 450K array and all robustly replicated ( $p < 10^{-3}$ ). The top two CpGs annotated upstream of ABR (cg01912040, cg10003262). All urine arsenic-associated CpGs were also associated with arsenic measured in drinking water ( $p < 0.05$ ). Meta-analysis ( $n=796$ ) identified 33 urine arsenic-associated CpGs (Bonferroni-corrected threshold  $p < 1.3 \times 10^{-7}$ ). Among meta-analysis arsenic associated CpGs, gene-specific expression and methylation was associated for six CpGs ( $p < 0.05$ ) and associated CpGs annotated to three genes (EFNA1, SPSB1, SQSTM1) in the TNF $\alpha$  signaling via NF $\kappa$ B pathway (enrichment  $p = 7.7 \times 10^{-4}$ ). Conclusions: The robust associations between arsenic exposure and DNA methylation observed in this work suggest that epigenetic alterations may be important mediators in arsenic toxicity and could be further investigated as biomarkers of exposure and effect in exposed populations.

## 003.01D. Environmental Disasters and Climatic Events

### 003.01.13. The Impact of Hurricane Sandy on Pregnancy Complications in Eight Affected Counties of New York State

Jianpeng Xiao

**Abstract:** Background: The frequency and intensity of natural disasters have increased during the past decades greatly. However, hurricane's effects on pregnancy remain not well known. Therefore, we investigated the short- and long-term impact of Hurricane Sandy on multiple pregnancy complications in eight affected counties in New York State. Methods: Using a time-series analysis (Poisson regression model), we assessed the percent increase of emergency department (ED) visits for pregnancy complications during Hurricane Sandy month (10/29/2012-11/27/2012) and 12 months following Hurricane Sandy period in the eight affected counties in southern New York State, compared to non-Sandy period using the 2005-2014 hospital discharge data, controlling for time trend, temperature, and air pollution. Results: ED visits for overall pregnancy complications increased 6.3% (95% confidence interval (CI): 2.2%, 10.5%) during the Sandy month. Especially, the ED visits increased significantly for threatened abortion (9.9%), threatened labor (10.1%), early onset delivery (115.9%), renal disease (73.2%), and diabetes (42.3%). The ED visits of spontaneous abortion, hypertension, mental health, genitourinary tract infections, and cardiovascular diseases did not increase significantly during the Sandy month. We also found that ED visits of mental health have increased gradually after Sandy, and peaked eight months later, with visits increasing 33.2%. Hypertension and renal disease also elevated 7-8 months after the hurricane period. Conclusions: Our findings suggest that Hurricane Sandy immediately affected pregnancy outcome, and remained for nearly a year. These findings have implications for decision-makers and pregnant women, given the increase in extreme weather.

### **O03.01.14. Volatile Organic Compounds and Pulmonary Function in Children: 1, 3, and 5 Years after the Hebei Spirit Oil Spill**

Hae-Kwan Cheong

**Abstract:** Background: Nearby citizens were exposed to large volumes of volatile organic compounds (VOCs) for four days after the Hebei Spirit oil spill. Objectives: To investigate the cross-sectional and longitudinal relationships between initial exposure to VOCs in children and loss of pulmonary function 1, 3, and 5 years after the exposure event. Methods: Cumulative ambient VOC concentrations over the four days immediately after the spill, including benzene, toluene, ethylbenzene, xylene, and total VOCs (TVOCs), were measured with a modeling technique. The forced expiratory volume in 1 s (FEV1) of 224 children was assessed by spirometry at 1, 3, and 5 years after the spill. Multiple linear regression and linear mixed models were used to evaluate the associations, with adjustment for smoking. Results: The levels of VOC exposure represented, in order of volume, were as follows: xylene (mean: 11.2 mg/m<sup>3</sup>/4 d), toluene (10.1), ethylbenzene (6.2), and benzene (2.3). Percent of predicted FEV1 had significantly decreased after 1 (100.7), 3 (96.3), and 5 years (94.6). In a cross-sectional design, toluene, ethylbenzene, xylene, and TVOCs were significantly associated with percent of predicted FEV1 after 1 and 3 years, and ethylbenzene, xylene, and TVOCs were marginally significantly associated with percent of predicted FEV1 after 5 years. In a longitudinal design, benzene, toluene, ethylbenzene, xylene, and TVOCs were significantly associated with percent of predicted FEV1. Conclusions: Exposure to oil-derived VOCs resulted in loss of pulmonary function among children. These declines were persistent and did not reverse during the 5 years following the oil spill.

### **003.01.15. Tropical Storms and Associated Risk to All-Cause, Accidental, Cardiovascular, and Respiratory Mortality in 78 United States Communities, 1988-2005**

Meilin Yan

*Meilin Yan<sup>1</sup>, Ander Wilson<sup>1</sup>, Roger Peng<sup>2</sup>, Mohammad Al-Hamdan<sup>3</sup>, William Crosson<sup>3</sup>, Andrea Schumacher<sup>1</sup>, Seth Guikema<sup>4</sup>, Brooke Anderson<sup>1</sup>*

Abstract: While risks of accidental deaths from tropical storms (e.g., drowning, carbon monoxide poisoning) have been well-documented, much less is known about risks for more common causes of mortality (e.g., cardiovascular, respiratory). Here, we conducted the first multi-year, multi-state epidemiological study to estimate the relative risks (RRs) of community-wide allcause, cardiovascular, respiratory, and accidental mortality associated with tropical storm exposure in the United States (US). To measure storm exposure, we used five hazard-related metrics-distance to storm track; cumulative rainfall; maximum sustained wind speed; flooding; and tornadoes. For each exposure metric, we modeled the association between community-level storm exposure and daily death counts in 78 large eastern US communities, 1988-2005, using a matched analysis of storm-exposed days versus similar unexposed days. We assessed risks for a window from two days before to seven days after the storm's closest approach. Over the study period, 92 Atlantic Basin tropical storms were considered based on US landfall or near-approach, with 70 communities exposed to at least one storm. Under windbased exposure metrics, we found substantially elevated risk for all mortality outcomes considered, with highest risk typically on the day the storm was closest. Based on windexposure, overall RRs of mortality during the full storm exposure window were 1.90 (95% CI: 1.58-2.29), 161.41 (61.62-422.80), 1.30 (0.97-1.76), 1.54 (0.70-3.39) for all-cause, accidental, cardiovascular, and respiratory mortality, respectively. These estimated associations may be dominated by extremely high risks during the few most severe storms (e.g., Andrew [1992], Katrina [2005]), a hypothesis we continue to explore. Our results suggest that very severe tropical storm exposures can have important mortality impacts beyond direct accidental deaths, including potentially important risks for cardiovascular and respiratory mortality.

### **003.01.16. Deepwater Horizon Oil Spill Exposures and Neurobehavioral Function in GuLF STUDY Participants**

#### Arbor Quist

**Abstract:** Background: The 2010 Deepwater Horizon (DWH) oil spill released over 5 million barrels of crude oil and exposed tens of thousands of clean-up workers to hydrocarbons and other harmful chemicals. Some hydrocarbons, such as toluene and xylene, have been found to have acute adverse effects on the central nervous system. However, no studies have examined the association between oil spill exposures and human neurobehavioral function. Methods: To examine how maximum total hydrocarbon (THC) exposure and various job classes are associated with neurobehavioral function, we used data from the GuLF STUDY (Gulf Long-term Follow-up Study), a large cohort of adults who worked on the DWH clean-up and response. THC exposure was estimated from a job-exposure matrix that linked air measurement data to self-reported job data. Participants were categorized into 6 job classes based on their job with the likely highest exposure. Several neurobehavioral outcomes were assessed at clinical exams 4-6 years after the spill with the Behavioral Assessment and Research System (BARS). We conducted multivariable linear regression of the relationships between maximum THC level and job classes with 15 neurobehavioral outcomes, stratified by smoking. Results: Never smokers performed better than current smokers on 12 of the 15 neurobehavioral outcomes. We observed significant associations between maximum THC level and decreased neurobehavioral performance for attention, response speed, and visual memory among never smokers, but no associations were observed among former or current smokers. By job class, never smokers who worked near the wellhead had higher THC exposure and lower neurobehavioral performance, especially in complex functions and memory, compared to administrative workers with low exposure. Conclusion: Oil spill exposure may be associated with impaired neurobehavioral function, especially memory and attention, but this effect appears to be limited to never smokers.

## S03.01A. Assessing Manganese Exposure in Pediatric Populations across the Globe

### S03.01.01. Pediatric Manganese Exposure and Neurocognition in Eastern Ohio

Erin Haynes

- 2. Cincinnati Children's Hospital Medical Center, Cincinnati, OH, United States.*

Abstract: Manganese (Mn) is both an essential element and neurotoxicant. Two communities in eastern Ohio have the two of the highest ambient Mn concentrations in the nation. Our goal is to address the communities' primary research question: "Does Mn affect cognitive development of children?" Children ages 7-9 were enrolled in the Communities Actively Researching Exposure Study (CARES) from Marietta, Cambridge, and East Liverpool, Ohio. CARES has been conducted using community-based participatory research principles. We conducted neurocognitive assessment (child IQ). Blood was analyzed for Mn and lead (Pb); hair were analyzed for Mn, and serum was analyzed for cotinine, a measure of second hand tobacco smoke. We used penalized splines to assess potential non-linear associations between biological measures and child IQ scores, followed by multivariable regression models with categorical variables based on quartiles of the distribution for biological measures. Both low and high Mn concentrations in blood and hair were negatively associated with child IQ scores. There was a negative association between hair Mn and child IQ in East Liverpool children. Serum cotinine was also negatively associated with child cognitive function. Community engagement has enhanced the research process and the translation of study findings for these communities.

### **S03.01.02. Manganese in Multiple Biomarkers and Neurodevelopment among Adolescents Residing near Ferro-Alloy Industry**

Birgit Claus Henn

*Birgit Claus Henn<sup>1</sup>, Manish Arora<sup>2</sup>, Chris Gennings<sup>2</sup>, Julia A. Bauer<sup>1</sup>, Christine Austin<sup>2</sup>, Yueh-Hsiu Mathilda Chiu<sup>2</sup>, Silvia Zoni<sup>3</sup>, Marco Peli<sup>3</sup>, Chiara Fedrighi<sup>3</sup>, Chiara Benedetti<sup>3</sup>, Brent A. Coull<sup>4</sup>, Robert Wright<sup>2</sup>, Donald Smith<sup>5</sup>, Roberto G. Lucchini<sup>2</sup>*

*3. University of Brescia, Brescia, Italy.*

*4. Harvard T.H. Chan School of Public Health, Boston, MA, United States.*

*5. University of California, Santa Cruz, Santa Cruz, CA, United States.*

**Abstract:** Introduction: Growing epidemiologic evidence suggests that environmental exposure to manganese (Mn) in childhood is associated with neurobehavioral decrements. However, substantial gaps remain in understanding Mn health risks among adolescents and in relation to varying biomarkers and timing of exposure. Methods: As part of the Public Health Impact of Manganese Exposure (PHIME) study, we measured Mn in blood, hair, nails, saliva, and urine collected from 10-14 year old Italian children (N~720) living near ferromanganese industry. Mn was also measured in deciduous teeth to represent prenatal, postnatal, and early childhood exposure periods. Neurobehavioral assessments, conducted concurrent with biological sample collection, included the Wechsler Intelligence Scale for Children, Conners Behavior Rating Scale, and California Verbal Learning Test. Multivariable models evaluated associations between each Mn biomarker and neurobehavior. Weighted quantile sum regression was used to estimate associations of a weighted cumulative Mn index and to identify the biomarker with the largest contribution to neurobehavior score. Results: We observed inverse associations between childhood Mn with cognition (e.g., saliva and verbal IQ,  $\beta=-1.4$ ,  $p=0.004$ ) and memory (saliva and short recall,  $\beta=-0.3$ ,  $p=0.001$ ). In contrast, early life Mn (teeth) was associated with improved scores of cognition (digit span backward,  $\beta=0.4$ ,  $p=0.05$ ), behavior (teacher-reported inattention,  $\beta=-0.07$ ,  $p=0.04$ ), and memory (sum of intrusions,  $\beta=-1.8$ ,  $p=0.03$ ). The weighted cumulative Mn index, which included blood, hair, nail, saliva and urine Mn, was associated with worse performance on all three neurobehavioral assessments (verbal IQ,  $\beta=-4.0$ ,  $p=0.001$ ; parent-reported inattention,  $\beta=0.05$ ,  $p=0.01$ ); saliva was the largest contributor to most associations. Conclusions: These results suggest a complex relationship between Mn and neurobehavior, whereby associations may differ by biomarker and timing of exposure.

### **S03.01.03. Prenatal Manganese and Behavioral Problems in 5-Year Old Children from the Infants' Environmental Health (ISA) Study**

Berna Van Wendel de Joode

*Berna Van Wendel de Joode<sup>1</sup>, Ana Maria Mora<sup>1</sup>, Leonel Córdoba<sup>1</sup>, Jorge Ernesto Peñaloza Castañeda<sup>1</sup>, Aligherie Fajardo Soto<sup>1</sup>, Donald Smith<sup>3</sup>, José Antonio Menezes-Filho<sup>2</sup>, Brenda Eskenazi<sup>4</sup>, Donna Mergler<sup>5</sup>*

1. *Universidad Nacional, Heredia, Costa Rica.*

3. *University of California at Santa Cruz, Santa Cruz, CA, United States.*
4. *University of California at Berkeley, Berkeley, CA, United States.*
5. *University of Quebec, Montreal, QC, Canada.*

**Abstract:** Background: Results from cross-sectional studies have shown excess manganese (Mn) may adversely affect children's neurodevelopment. However, data from prospective studies are limited. We examined whether prenatal manganese was associated with behavioral problems in children from the 'Infants' Environmental Health (ISA)' birth cohort study in Costa Rica, who live near banana plantations aerially sprayed with mancozeb, a Mn-containing fungicide. Methods: We interviewed mothers from 5-year old children (mean 5.7 ± 0.4 years) (n=292) about children's behavior during the last two months using the Child Behavior Checklist (CBCL). We measured Mn concentrations in maternal blood (MnB) and hair (MnH) samples collected 1-2 times during pregnancy, and calculated mean MnB and mean MnH concentrations. We analyzed internal consistency of CBCL and only analyzed scales with Cronbach-alfa >0.7. We examined linear and nonlinear relationships for log10-MnH and MnB concentrations and CBCL scales (Internalizing, Externalizing, Aggressive, Withdrawn) in separate models. We adjusted models for children's age at assessment, parity, HOME score, maternal education and maternal depression. We also revised effect modification by child sex. Results: Median (P25-P75) mean MnB and mean MnH during pregnancy were 24.0 µg/L (20.3-28.3) and 1.6 µg/g (0.8-3.3), respectively. Higher MnB concentrations were associated with more internalizing problems for girls ( $\beta=0.21$  95%CI: -0.02, 0.43) but not for boys ( $\beta=-0.02$  95%CI: -0.25, 0.21). MnB was not associated with other CBCL scales. We observed null associations for log10-MnH, and did not find evidence for non-linear relationships for MnB or MnH. Conclusions: Further studies, which include maternal and cord blood concentrations, as well as other essential elements, such as iron, are needed to understand whether maternal excess Mn during pregnancy contributes to behavioral problems in young children. Effects of excess Mn may be different for boys and girls.

### **S03.01.04. Prenatal and Early Postnatal Dentine Mn, Zn and Pb and Childhood Behavior**

Megan Horton

*Megan Horton<sup>1</sup>, Leon Hsu<sup>1</sup>, Birgit Claus Henn<sup>2</sup>, Amy Margolis<sup>3</sup>, Christine Austin<sup>1</sup>, Katherine Svensson<sup>1</sup>, Lourdes Schnaas<sup>4</sup>, Chris Gennings<sup>1</sup>, Howard Hu<sup>5</sup>, Robert Wright<sup>1</sup>, Martha M. Téllez-Rojo<sup>6</sup>, Manish Arora<sup>1</sup>*

- 5. University of Toronto, Toronto, PE, Canada.*
- 6. National Institute of Public Health, Cuernavaca, Mexico.*

**Abstract:** Background: Metal exposure alters neurodevelopmental outcomes; little is known about critical windows of susceptibility when exposure exerts the strongest effect. Objective: To examine associations between prenatal and early postnatal manganese (Mn), zinc (Zn) and lead (Pb) and childhood behavior. Methods: 153 subjects enrolled in a Mexico City birth cohort study provided deciduous teeth. We estimated weekly prenatal and postnatal dentine Mn, Zn and Pb concentrations in teeth using laser ablation-inductively coupled plasma-mass spectrometry (LA-ICPMS) and measured behavior at ages 6-16 years using the Behavior Assessment System for Children, 2nd edition (BASC-2). We used distributed lag models and lagged weighted quantile sum regression to identify the role of individual and mixed metals on behavioral symptoms controlling for maternal education and gestational age. Results: Prenatal dentine Mn appears protective against behavioral problems, specifically hyperactivity and attention. Postnatal dentine Mn is associated with increased internalizing problems, specifically anxiety. At 6 months (mo), a 1-unit (unit = 1SD of log concentration) increase in Mn associated with a 0.18-unit (unit = 1SD of BASC-2 score) and 0.25-unit increase in the BASC-2 anxiety score, respectively. Postnatal Pb is associated with higher anxiety symptoms. At 12 mo, a 1-unit increase in Pb is associated with a 0.4-unit increase in anxiety. Examined as a mixture, we observe two windows of susceptibility to increased anxious symptoms: The first window (0-8 mo) is driven by Mn, the second window (8-12 mo) is driven by the mixture and dominated by Pb. A 1-unit increase in the mixture is associated with a 0.7-unit increase in SD of anxiety score. Conclusions: Prenatal dentine Mn may be protective, while postnatal Mn may increase risk for adverse behaviors. In combination, Mn, Zn and Pb may have an adverse impact on behavior.

S03.01B. Environmental Exposures and Breast Cancer across the Life-Course: Interdisciplinary Collaborations to Stimulate New Research Approaches, Improve Exposure Assessment during Critical Windows, and Accelerate the Translation of Research Findings into Disease

**S03.01.05. Study Design Considerations when Measuring Exposure Biomarkers of Non-Persistent Endocrine Disruptors in Epidemiologic Studies of Chronic Diseases Including Breast Cancer**

Susan Pinney

*Susan M. Pinney*<sup>1</sup>

*1. Dept of Environmental Health, U of Cincinnati College of Medicine, Cincinnati, OH, United States.*

Abstract: Endocrine disrupting chemicals are believed to increase risk of breast cancer. Exposure to EDCs is challenging to study with environmental biomarkers because they often have short half-lives and their exposure source may be linked to personal products used only during certain seasons, days, or certain times of the day. Designing studies incorporating the exposure biomarkers of these chemicals requires many critical decisions including consideration of the limit of detection (LOD) and quality assurance measures. The toxicokinetics and toxicodynamics of these chemicals likely vary by age and therefore, correlations of the different biomarkers available in urine vs. serum may also vary during the different windows of exposure. Benefits versus costs (both financial and non-financial) of repeated measurements over time need to be considered. Other exposure assessment and study design challenges include the content of the consent form, the biomedia to use, the time of sample collection, and laboratory selection. Protocols for sample collection and processing should consider feasibility within the overall study program, acceptability to the study participants, and especially elimination of potential sources of sample contamination. The effort to maintain a complete biospecimen inventory, and to track distribution of biospecimens, is substantial but absolutely necessary. This presentation will review these challenges and provide helpful suggestions for meeting them in design of epidemiologic studies examining exposure to EDCs with periodic use and short half-lives.

### **S03.01.06. Using Breast Density as an Intermediate Biomarker of Environmental Influence on Breast Cancer Risk**

Celia Byrne

*Celia Byrne<sup>1</sup>, Hristina Denic-Roberts<sup>1</sup>*

*1. Preventive Medicine and Biostatistics, Uniformed Services University, Bethesda, MD, United States.*

Abstract: Analyzing intermediate biomarkers of environmental exposures allows for detection of effects many years prior to disease onset. Mammographic density differences identify environmental factors of breast cancer risk even 5, 10, or 15 or more years prior to the onset of breast cancer. Compared to having low levels, women with higher levels of mammographic breast density have 4 to 6-fold increased risk of developing breast cancer. Identifying biological effects closer to the time of exposure allows for early prevention and/or intervention efforts. Mammographic breast density is not static throughout a woman's life. Most studies of mammographic density and breast cancer involved women older than 40, when the prevalence of mammography use and breast cancer incidence increases. As women go through the menopausal transition breast density declines but the rate of decline differs among women and serves as risk indicator. Recent studies using non-radiologic techniques examined breast tissue density in girls and younger women indicating that breast density serves as a biomarker of environmental exposures throughout the life-course. Examining the cumulative impact of endocrine disrupting chemicals (EDC) on breast density will clarify the EDC' breast cancer risk impact. Recent studies demonstrated that breast cancer risk increased, for women whose breast density increased when taking exogenous hormones, and conversely risk declined, for women whose breast density declined when taking selective estrogen receptor modulating treatments. Change in breast density mediated the effects of these hormonal treatments. This presentation highlights the benefits and concerns with interim biomarkers of risk in environmental studies of long latency diseases using the merits of breast density as a marker of EDC' effect on breast cancer risk as an example.

### **S03.01.07. Exploring Environmental Chemicals and Risk of Breast Cancer during the Menopausal Transition**

Susan Neuhausen

*Susan Neuhausen<sup>1</sup>, Noriko Kanaya<sup>1</sup>, Yuan C. Ding<sup>1</sup>, Susan E. Hurley<sup>2</sup>, David Nelson<sup>2</sup>, June-Soo Park<sup>3</sup>, Peggy Reynolds<sup>2</sup>, Shiuan Chen<sup>1</sup>*

*3. Environmental Chemistry Lab- State of California, Berkeley, CA, United States.*

Abstract: Teasing out the biologic mechanisms of endocrine-disrupting chemicals (EDCs) in epidemiologic studies is complicated given their heterogeneity, and assessing the effects of exposures in vitro assays and in vivo animal studies may not reflect what happens in human populations. Therefore, using a transdisciplinary approach with a population-based epidemiologic study, in vitro assays, and in vivo mouse models, offers a targeted opportunity to evaluate the role of EDCs in promoting breast cancer during the menopausal transition. We are specifically investigating the effects of three polybrominated diphenyl ethers (BDE-47, BDE-100, and BDE-153). Using blood samples collected during the menopausal transition from women in the prospective California Teachers Study (CTS) cohort, we are assessing the effects of PBDE levels on the epigenome through miRNA and global and gene methylation assays, on total estrogenic activity, and on risk of developing breast cancer. In in vitro experiments in breast cell lines, we are measuring the effects of PBDEs at a range of levels, including at the CTS serum levels, to assess their effects on the activity of the estrogen and progesterone receptors and aromatase, as well as on the epigenome, transcriptome, and cell proliferation. Initial results suggest that BDE-47 acts as a mild ER- $\alpha$  agonist and BDE-100 and BDE-153 act as weak antagonists. In in vivo mouse models, we are testing whether combined effects of PBDEs at the levels seen in serum of the CTS samples cause mammary gland lesions. We first are studying ovariectomized mice, which have minimal estrogenic activity in their bodies, and then will use an ovarian-failure mouse model to represent the menopausal transition. Definitive changes in uterus weight and gene expression profiles have been observed in mice following 1-week feeding of PBDE-containing diet.

### **S03.01.08. Environmental Chemicals and Postpubertal Breast Composition in a Cohort of Girls from Chile: Results from a Pharmacokinetics Study of Zeranol**

Vincent Bessonneau

*Vincent Bessonneau<sup>1</sup>, Brian Buckley<sup>2</sup>, Julia Santucci-Pereira<sup>3</sup>, Jose Russo<sup>3</sup>, Julia Brody<sup>1</sup>, Camila Corvalan<sup>4</sup>, Ruthann Rudel<sup>1</sup>, Karin Michels<sup>5</sup>*

- 5. Fielding School of Public Health, UCLA, Los Angeles, CA, United States.*

Abstract: As part of the NIEHS Breast Cancer and the Environment Research Program (BCERP), we are investigating associations between several endocrine disrupting chemicals (EDCs), including zeranol (Zer) and its metabolites, and breast density, hormones levels, and pubertal timing in a cohort of 400 girls in Santiago, Chile. Zeranol is a non-steroidal agent with potent estrogenic activity and is widely used as a growth promoter for cattle. It is also a fungal component found on grains. Parallel investigation of zeranol is being conducted in female rats exposed by oral gavage from weaning to post-natal day (PND) 42, and effects are being evaluated on mammary gland development and tumor susceptibility. This presentation will highlight the relation between urine and blood levels of Zer and its metabolites in a subset of 25 girls from a Chilean cohort. These relations between urine and blood levels in the cohort subset will be used to estimate blood levels in girls in the full cohort where Zer will be assessed in urine samples. We will also compare the blood and urine levels measured in girls with blood levels measured in rodents dosed with Zer at levels intended to mimic human exposure. Animal experiments can complement human epidemiology, providing information about mechanisms that cannot be accessed for study in humans. Pharmacokinetic studies can aid translation from animals to human health as well as from inexpensive, non-invasive urine samples to blood.

## S03.01C. Health Earth: Planetary Health Affects Everyone's Health

### S03.01.09. The Impact of Climate Change on Displacements of Population

Wael Al-Delaimy

*Wael Al-Delaimy<sup>1</sup>*

*1. Family Medicine and Public Health, UC San Diego, San Diego, CA, United States.*

**Abstract:** Background: As climate change and its impacts become more evident through more frequent and extreme weather events, the most vulnerable populations and nations will suffer the most, and manifest through ever growing waves of migration in search of a better life. Method: Data will gathered on the Middle East as an example and a unique case study to understand this impact of climate change as a major determinant of health. Results: The Middle East conflicts and related migration result from a more complex accumulation of factors than simply attributing them to climate change. The heat waves, water scarcity, political instability, and desert storms are factors linked to global warming and planetary health that is going to impact the most vulnerable in societies of the Middle East. Migration of refugees through and from this region will continue to be a problem for the rest of the world. This will also be discussed in relation to current and future scenarios of climate change. The lack of public discussion and the low priority by governments regarding mitigation of climate change are some of the tasks that can be addressed at the international level to raise awareness of the consequences of climate change. Conclusion: Climate change is a manifestation of the planet's deteriorating health and in turn will be impacting the health of vulnerable populations in volatile regions such as the Middle East where multiple factors are creating the worst consequences of climate change.

### **S03.01.10. Holistic Effects of Climate Change on the Culture, Wellbeing and Health of the Saami, the Only Indigenous People in Europe**

Jouni Jaakkola

*Jouni J. Jaakkola<sup>1</sup>, Suvi Juntunen<sup>1</sup>, Klemetti Näkkäläjärvi<sup>2</sup>*

*1. Center for Environmental and Respiratory Health Research, University of Oulu, Oulu, Finland.*

*2. University of Lapland, Rovaniemi, Finland.*

**Abstract:** Background: Climate change will affect all populations, but particularly those living in northern latitudes where the predicted environmental changes are the most dramatic. The Saami are indigenous people living in northern Europe. Their traditional livelihoods are reindeer herding, fishing, gathering, hunting and handicrafts and their way of life is based on sustainable use of natural resources and living within nature. Ironically, this sustainable traditional way of life is threatened by changing environmental conditions linked to climate change. This presentation elaborates the effects of climate change, which are likely to be holistic, influencing culture, wellbeing and health. Methods: We present a multidisciplinary theoretical framework and empirical evidence based on a systematic literature search. Results: There is evidence from the Saami communities that the possibilities to practice Saami way of life and traditional livelihoods have already become weaker in Nordic Countries due to environmental, financial, legislative and societal pressures. Some of these pressures are linked to the emerging climate change. These changes in way of life have cultural, mental and social implications to Saami communities. There is evidence a major contributor to mental illness and associated conditions among indigenous populations is chronic psychosocial stress linked to rapid economic development and social transformations over the past half-century and this development is expected to accelerate due to climate change. Health and well-being of Saami community is therefore a serious concern in a changing climate. Conclusions: In order to Saami people to maintain their traditional way of life and identity, the effects of climate change on Saami people have to be identified and monitored. Adaptation to climate change requires information on the regional and long-term effects of climate change on the environment, health and well-being.

### **S03.01.11. How Development Choices Could Alter the Capacity of Health Systems**

Kristie Ebi

*Kristie L. Ebi<sup>1</sup>, Sam Sellers<sup>1</sup>*

*1. Department of Global Health, University of Washington, Seattle, WA, United States.*

**Abstract:** Background: Individual and collective choices will determine the pattern of demographic, socioeconomic, and technologic changes that will, in turn, affect the transitioning to a more resilient and sustainable world, including the burden of climate-sensitive health outcomes. Methods: Using a set of socioeconomic development trajectories, the Shared Socioeconomic Pathways (SSPs), along with the World Health Organization's Operational Framework for Building Climate Resilient Health Systems, we extend existing narratives to illustrate how aspects of health systems are likely to change over this century, and the implications of these trends for population health. Five narratives describe worlds with varying degrees of challenges to adaptation and mitigation. Results: Very different health system capacities and burdens of climate-sensitive health outcomes will likely arise under different development pathways, with substantial implications for population health. Transitioning to a more resilient and sustainable world to prepare for and manage the effects of climate change is likely to result in strengthened capacity to manage impacts that do arise and to better health outcomes overall. Continued significant fossil fuel use will likely result in high burdens of preventable conditions, such as undernutrition, malaria, and diarrheal diseases, coupled with reduced capacity to manage these challenges. The magnitude and pattern of health burdens and capacity of health systems will vary under other development pathways. Further research should examine how health systems are coping with health and climate change challenges, and the information, tools, and resources need to increase the capacity to manage future climate change-related health risks.

### **S03.01.12. Revisiting the Earth Charter and Our Ethical Obligations to Planetary Health**

Colin Soskolne

*Colin L. Soskolne*<sup>1</sup>

*1. Health Research Institute, Universities of Alberta and Canberra, Montreal, QC, Canada.*

**Abstract:** Background: Values and principles for global norms are urgently needed to incentivize individual and collective corrective action for transitioning humankind from its current unsustainable global trajectory. The Earth Charter (EC) provides such a set of values and ethical principles. **Methods:** Empirical observations of existing global-scale trends in all that sustains life are considered for seeking a solution to the current trajectory where humankind, embedded in the ecosphere, is destined to collapse. Comparative assessments of attempts to implement the EC in the few regions of the world with the foresight to do so, provide hopeful case studies demonstrating positive changes toward sustainability. **Results:** Observations since 2000, when the EC was formally adopted, show that its adoption remains far from complete. Further observations demonstrate that all indicators of sustainability, instead of improving, are worsening. In this presentation, the significance of the EC's values and principles are shown in different contexts. Case studies reveal how the EC is being incorporated into governance in Mexico, and from the City Government of São Paulo, Brazil, and in universities in Spain, Greece, and Florida, USA. These examples demonstrate the EC's utility, certainly as an educational instrument. Its implementation in a few parts of the world provides examples demonstrating that its integration into the fabric of life is attainable. **Conclusions:** The EC is a tool for aligning values and ethical guidance in our personal lives, as well as in all socio-economic organization and governance, if a sustainable path for humanity is to be achieved. If accomplished on a grand scale, the human enterprise would immediately shift from its current trajectory toward the collapse of life as we know it, to a path of sustainability. The role of environmental epidemiology in evaluating the potential of the EC to limit impacts from upstream determinants of health warrants consideration.

## S03.01D. Healthy Schools: Understanding Indoor Environmental Quality, Occupant Health, and Academic Performance

### **S03.01.13. Assess School Environmental Effects on Occupants' Health and Evaluate Environmental Policies' Impacts**

Shao Lin

*Shao Lin<sup>1</sup>, Yi Lu<sup>1</sup>, Wayne R. Lawrence<sup>2</sup>, Emily Lipton<sup>3</sup>, Ziqiang Lin<sup>4</sup>, Haider Khwaja<sup>1</sup>, Xiaobo Xue<sup>1</sup>, Chris Lim<sup>5</sup>, George Thurston<sup>5</sup>*

- 1. Department of Environmental Health Sciences, University at Albany, State University of New York, Rensselaer, NY, United States.*
- 2. Department of Epidemiology and Biostatistics, University at Albany, State University of New York, Rensselaer, NY, United States.*
- 3. Department of Health Policy, Management, and Behavior, University at Albany, State University of New York, Rensselaer, NY, United States.*
- 4. Department of Mathematics and Statistics, University at Albany, State University of New York, Albany, NY, United States.*
- 5. Department of Environmental Medicine, New York University School of Medicine, New York, NY, United States.*

**Abstract:** Background: Over half of schools surveyed in the U.S. have reported at least one environmental issue. To date, few studies have assessed private school environment, how school exposures affected occupants, and environmental policies' impacts on children's health. Thus, we evaluated private school environment; assessed if school environment affects occupants' health; and examined if environmental policies reduced pollution and childhood asthma. Methods: We administered surveys to superintendents of NYS private and public schools to obtain their perception and concerns of the school environment. Working with NYS Teacher Union, we conducted a statewide survey among public school teachers to assess if school indoor air quality (IAQ) affected teachers' health. In addition, we also evaluated the impact of EPA NOx policy on childhood asthma. Results/Conclusion: We found that 92% of private schools reported not having an established IAQ program, 31% perceived IAQ in their school as poor; 69% claimed there were visible signs of moisture damage; and 61% are in close proximity to highway and/or train tracks. The teacher survey showed that experiencing  $\geq 1$  symptom was significantly associated with dust, dust reservoirs, paint odors, mold, and moldy odors (PR ranged from 1.65 - 3.67). Poor air conditioner use was significantly associated with poor test scores in children. Evaluating EPA's NOx Policy on respiratory diseases among children in NYS, we found the mean daily ozone concentrations significantly declined statewide and in 5 out of 8 regions following the NOx reduction policy. The adjusted respiratory hospitalizations also significantly declined statewide following the policy after controlling for temporal trends. We conclude that private schools have many environmental problems and school IAQ significantly affected occupants' health. Environmental policies may have positive impact on reducing air pollution and asthma burden.

### **S03.01.14. School Operations Reporting and Student Academic Achievement**

Jenny Apriesnig

*2. Department of Agricultural & Resource Economics, Colorado State University, Fort Collins, CO, United States.*

Abstract: Understanding the factors that influence student learning outcomes is critically important to school administrators tasked with designing and staffing schools. Considerable research has assessed differences in student achievement by focusing on teacher quality, class size, teacher turnover, and student teacher ratio. While discerning the impact that teachers have on students is of obvious importance, there is also interest in understanding how the built environment influences student achievement. Here, we assess how the environmental characteristics of schools influence student achievement. We use a panel dataset from a suburban Denver school district of approximately 41,000 students to understand how school characteristics impact student achievement. Specifically, we evaluate the relationship between school environmental characteristics and standardized test scores. The school environmental characteristics include thermal comfort, acoustics, visual quality, indoor air quality, and Energy Star rating, which are specific to each of the 54 schools in the district. By observing students that transition between schools as they move from elementary to middle schools and from middle to high schools, we evaluate how the differing school environmental characteristics impacts achievement. When controlling for other school characteristics and student demographics, we find a school's Energy Star score, acoustics, and indoor air quality have a positive relationship with student test scores, while thermal comfort consistently has a negative relationship with test scores. The positive impact of the Energy Star score is particularly robust to differences in how the achievement model is specified. Given this, we evaluate the specific components of the Energy Star score. Overall, the results highlight the importance of evaluating both the environmental impacts and the impacts on student achievement associated with the construction of energy efficient schools.

### **S03.01.15. School Environment, Indoor Air Quality, Student Performance and Health**

Meredith McCormack

- 2. Johns Hopkins University, Baltimore, MD, United States.*
- 3. University of Minnesota, Minneapolis, MN, United States.*

**Abstract:** School environment is a key exposure for school age children. Understanding the link between school community, school building, and indoor environment characteristics and student performance and health provides insight as to means of improving student performance and health. A large school renovation program in the mid-Atlantic region provided an opportunity to study the relationship between indoor air quality and other school environmental factors and student performance, school climate, and health. Building inspection data and community-level data were linked to student administrative data from an urban school district in the mid-Atlantic region. Facility conditions and school neighbourhood characteristics were associated with student math and reading performance with chronic absences. In a subset of schools planned for renovation, school building factors and outdoor environmental characteristics were associated with indoor air quality. Indoor air pollutants, including PM<sub>2.5</sub>, NO<sub>2</sub>, CO<sub>2</sub>, exceeded WHO or ASHRAE guideline recommendations for a portion of the time monitored. Twenty percent of the daily average PM<sub>2.5</sub> and 25% of the hourly average NO<sub>2</sub> concentrations exceeded corresponding WHO guidelines for indoor air. Seasonal variability was statistically significant for indoor NO<sub>2</sub> and CO<sub>2</sub> concentrations, with higher exposures in fall and winter, suggesting a role for improvements in ventilation. Temperatures were frequently (~2/3 of school day) outside of recommended ranges. These findings provide evidence that community and school environments are associated with academic achievement and attendance, suggesting that opportunities to improve school conditions may translate to improvement in school performance for students.

### **S03.01.16. Environmental Quality, Health and Learning in Conventional and High Performance School Buildings**

Stuart Batterman

*Stuart Batterman<sup>1</sup>, Cheryl Somers<sup>2</sup>, Geoffrey Thun<sup>1</sup>, Nan Yan<sup>1</sup>*

*1. UM, Ann Arbor, MI, United States.*

*2. Wayne State, Detroit, MI, United States.*

**Abstract:** Aims: Schools are critical indoor environments that can affect the health, comfort and performance of children and teachers alike. We discuss lessons learned in an intervention study of schools and highlight issues related to ventilation, filtration and outcomes assessments. Methods: We compare indoor environmental quality (IEQ) parameters in a 37 recently constructed or renovated elementary school buildings, balanced between high performance and conventional buildings located in the US Midwest. We then compare results of interventions designed to increase ventilation and particle filtration (from MERV8 to MERV13) using a case-crossover design and repeated measures involving 550 students and 2 schools. We report on attendance, cardiopulmonary fitness using the Progressive Aerobic Cardiovascular Endurance Run (PACER) test, and student learning. We also characterize IEQ parameters in four classrooms in each school, using multiday measurements. The buildings varied in design, HVAC system, size, and other factors. Only 22% of classrooms met recommended minimum ventilation rates. Occupancy in many classrooms was highly variable, thus, the use of carbon dioxide (CO<sub>2</sub>) concentrations as a tracer for determining ventilation rates should use the transient mass balance method. It was sometimes difficult to detect significant differences in air change rates when ventilation rates were increased, and improving filtration did not always lower particulate matter concentrations. We show that increasing ventilation with low efficiency filters can increase PM<sub>2.5</sub> levels. Students and teachers had positive experiences with the PACER test. Conclusion: Intervention studies have strengths and allow investigation of both IEQ and student performance. Interventions must be carefully selected to ensure meaningful exposure contrasts and yield meaningful epidemiological evidence.

## S03.01E. Multidisciplinary Approaches for Traffic Related Burdens through Route Specific Exposures and Dose to Noise, Air Pollution and Quality of Life: Making Better Measurements

### S03.01.17. Understanding Traffic-Related Air Pollution Exposures through Mobile Monitoring

Abstract: Human exposures to air pollution can vary sharply in space and time. Carefully designed mobile sampling campaigns are now able to reveal patterns of long-term ambient air pollution concentrations at fine scales ( $\ll 100$  m). Here, we report on a campaign where two specially equipped Google Street View cars mapped spatial patterns of air quality in the San Francisco Bay Area between May 2015 and December 2017. Cars were outfitted with reference-grade instruments to measure NO, NO<sub>2</sub>, black carbon (BC) and ultrafine particle number count at  $\sim 1$  Hz. During a 30-month campaign, measurements occurred on most weekdays during daytime hours, resulting in a large dataset:  $\sim 10$ M samples collected during  $> 4000$  h, encompassing 100k km of driving. First, we sampled every road 20-50 $\times$  within three neighborhoods ( $\sim 30$  km<sup>2</sup>) in Oakland, CA, during the first year of measurements. We found persistent fine-scale variability in pollution exists within many neighborhoods. In some neighborhoods, prominent  $\sim 50$ -200 m sized hotspots of elevated primary pollutants were ubiquitous, with pollutant levels varying by 5-8 $\times$  within many city blocks. Next, during 1.5 years of follow-up measurements, we mapped pollutant concentrations in rural, suburban, and dense urban neighborhoods throughout the SF Bay Area. These measurements reveal how within-neighborhood pollution structure is overlaid on top of regional spatial gradients in air quality. Repeated measurements over the 2.5-year period demonstrate persistent spatial variability over time. Patterns of NO, NO<sub>2</sub> and BC in Oakland had high correlation ( $r^2 > 0.85$ ) between the first and second years of measurement. Short-term measurement periods ( $\sim 1$ -2 months) were sufficient to reproduce overall spatial patterns, albeit with  $\pm 30\%$  bias in mean concentrations relative to annual-average conditions. This presentation summarizes how routine mobile air pollution monitoring reveals new information about spatial variability in population exposure to air pollution.

### **S03.01.18. Wearable Sensors for Geolocation, Physical Activity and Air Pollution: Challenges and Opportunities**

Juan Orjuela

*Juan P. Orjuela<sup>1</sup>, Audrey de Nazelle<sup>1</sup>*

*1. Centre for Environmental Policy (CEP), Imperial College London, London, United Kingdom.*

**Abstract:** Introduction: Procedures for measuring continuous data on geolocation, physical activity (PA), and air pollution (AP) have improved greatly in recent years but storing, cleaning and analyzing these can be challenging. Data collected from mobile phones is useful to estimate for example geolocation, transport mode, and PA levels, but more data does not always lead to better outcomes. Method: We use the results from three different studies (AirMAP, CAVA and PASTA) to illustrate the challenges in managing datasets for AP exposure estimates, and comment on their strengths and weaknesses. The datasets vary greatly: AirMAP was part of the Telecom Italia Big Data challenge 2015 which combined aggregated data from cellular towers (~8 million users) in grid cells of varying sizes (10 - 300m) in seven Italian cities; in CAVA, GPS and accelerometer readings derived from a smartphone app were collected from 180 participants in Barcelona; PASTA collected detailed geolocation, PA, and AP exposure data from 120 free-living individuals in three European cities using separate monitors for each in a relatively burdensome and resource intensive approach. For each study, daily exposures estimated as a function of daily activity patterns were compared to estimates based on home location. Results: Processing large and complex datasets to identify people's daily activities and account for microenvironmental concentrations in estimating personal exposures is still challenging. Mode for example is key in daily pollutant intake (modal choice may result in differences of up to 20%) but identifying it is a difficult task. AirMAP data suggests that home-based exposures overestimate daily activity-based exposures (by 6%), contrary to the other two studies (~18%). Conclusion: The comparison gives insights into difficulties of collecting, processing and interpreting data from current state of the art wearable devices, and into opportunities for large scale ubiquitous sensing.

### **S03.01.19. A High Resolution Spatiotemporal Model for In-Vehicle Black Carbon Exposure: First Application on Epidemiological Cohorts**

Luc Dekoninck

*Luc Dekoninck<sup>1</sup>, Luc Int Panis<sup>2</sup>, Ernst Rietzschel<sup>3</sup>*

*1. Informationtechnology, Ghent University, Ghent, Belgium.*

*2. Traffic and Mobility, Hassel University, Diepenbeek, Belgium.*

*3. Biobanking & Cardiovascular Epidemiology, Ghent University and University Hospital, Ghent, Belgium.*

Abstract: Several studies have shown that a significant amount of daily air pollution exposure is inhaled during trips. In this study, car drivers assessed their own black carbon exposure under real-life conditions (223 h of data from 2013). The spatiotemporal exposure of the car drivers is modeled using a data science approach. In-vehicle exposure is highly dynamical and is strongly related to the local traffic dynamics. An extensive set of potential covariates was used to model the in-vehicle black carbon exposure with a temporal resolution of 10 s. Traffic was retrieved directly from traffic databases and indirectly by attributing the trips through a noise map as an alternative proxy for traffic. Modeling by generalized additive models (GAM) shows non-linear effects for meteorology and diurnal traffic patterns. A fitted diurnal pattern explains indirectly the complex diurnal variability of the exposure due to the non-linear interaction between traffic density and distance to the preceding vehicles. An external validation, based on a dataset gathered in 2010-2011, quantifies recent exposure reductions inside cars at 33% (mean) and 50% (median). The EU Euro 5 PM emission standard (in force since 2009) explains the largest part of the discrepancy between the measurement campaign in 2013 and the validation dataset. An in-depth analysis of the model covariates and modelling approach will be discussed. The requirements of the epidemiological databases to enable health evaluations will be summarized. A first real-life application of the model on an epidemiological cohort will be introduced.

### **S03.01.20. Merging Mobile Measurements, Traffic Emissions Models, and Land Use Regression Towards Real-Time Estimation of Traffic-Related Air Pollution**

Steve Hankey

*Steve Hankey<sup>1</sup>, Jianhe Du<sup>2</sup>, Jinghui Wang<sup>2</sup>, Hesham Rakha<sup>3</sup>, Peter Sforza<sup>4</sup>*

- 1. School of Public and International Affairs, Virginia Tech, Blacksburg, VA, United States.*
- 2. Virginia Tech Transportation Institute, Virginia Tech, Blacksburg, VA, United States.*
- 3. Civil and Environmental Engineering, Virginia Tech, Blacksburg, VA, United States.*
- 4. Center for Geospatial Information Technology, Virginia Tech, Blacksburg, VA, United States.*

**Abstract:** Background: Current Land Use Regression (LUR) modeling approaches lack the spatiotemporal precision needed to match people's time-activity patterns for exposure assessment. We developed spatiotemporal LUR models of Particle Number (PN) and Black Carbon (BC) concentrations using two pieces of information: (1) mobile monitoring and (2) on-road emissions estimates from the INTEGRATION microscopic traffic simulation model which tracks vehicle movements, fuel consumption, and emissions every second. Methods: We employed mobile monitoring to collect ~120 hours of PN and BC measurements in Blacksburg, VA. Data collection was stratified by time of day (~10 hours of monitoring for each hour during 7am-7pm). We calibrated the INTEGRATION traffic emissions model to estimate hourly PN and BC emissions (100m spatial scale). We combined these datasets, along with traditional LUR covariates (e.g., land use variables), for model building. We developed and compared three types of models: (1) daytime average models that pool all mobile measurements, (2) hourly models (i.e., single model for each hour of day) and (3) spatiotemporal models (single model incorporating hour of day as a predictor). Results: Model fit for the daytime average models (adj-R2 for PN [BC]: 0.72 [0.66]) were comparable to models developed using fixed-site measurements. The hourly models (i.e., 12 separate models) had modest model fit (mean PN [BC] adj-R2: 0.52 [0.36]). The spatiotemporal models had the poorest model fit among model-types (adj-R2 for PN [BC]: 0.46 [0.27]). Results for the temporally resolved models were comparable to other mobile monitoring campaigns that attempted to model long-term averages suggesting it is possible to develop models with both spatial and temporal precision for real-time dissemination. Conclusions: Our approach to model traffic-related air pollution allows for matching the temporal and spatial resolution of people's time-activity patterns towards improved exposure assessment.

S03.01F. NASA Applications for Public Health and Air Quality Models and the Translation of Research Into Policy and Other Decision Making

**S03.01.21. NASA Applications for Public Health and Air Quality Models and Decisions Using Earth Observation Systems**

John Haynes

*Sue M. Estes<sup>1</sup>, John Haynes<sup>1</sup>*

*1. Applied Sciences, NASA, Washington, DC, AL, United States.*

Abstract: As part of NASA approach and methodology they have used Earth Observation Systems and Applications for Public Health and Air Quality Models to provide a method for bridging gaps of environmental, spatial, and temporal data for tracking disease. Health providers and researchers need environmental data to study and understand the geographic, environmental, and meteorological differences in disease. Satellite remote sensing of the environment offers a unique vantage point that can fill in the gaps of environmental, spatial, and temporal data for tracking disease. This presentation will demonstrate the need for collaborations between multi-disciplinary research groups to develop the full potential of utilizing Earth Observations in studying health. Satellite earth observations present a unique vantage point of the earth's environment from space, which offers a wealth of health applications for the imaginative investigator. The presentation is directly related to Earth Observing systems and Global Health Surveillance and will present research results of the remote sensing environmental observations of earth and health applications, which can contribute to the public health and air quality research. As part of NASA approach and methodology they have used Earth Observation Systems and Applications for Public Health and Air Quality Models to provide a method for bridging gaps of environmental, spatial, and temporal data for tracking disease. This presentation how weather will provide an overview of projects dealing with infectious and water borne diseases and how environmental variables effect human health. This presentation will provide a venue where the results of both research and practice using satellite earth observations to study weather and it's role in public health research.

### **S03.01.22. Searching Panacea for Cholera**

Antarpreet Jutla

*Antarpreet Jutla<sup>1</sup>, Anwar Huq<sup>2</sup>, Rita Colwell<sup>2</sup>*

*1. West Virginia University, Morgantown, WV, United States.*

*2. University of Maryland, College Park, MD, United States.*

Abstract: Cholera is a medically treatable disease, however, outbreak of this infection still pose a major public health threat across globe. The causative agent of the disease, *Vibrio cholerae*, cannot be eradicated from the environment, primarily due its ability to survive and adapt to a host of climatic conditions. Data on disease prevalence and infectious pathogens is sparingly collected/available in region(s) where climatic variability and extreme natural events intersect with population vulnerability (such as lack of access to water and sanitation infrastructure). Therefore, traditional time series modeling approach of calibration and validation of a model is generally inadequate. Hence, prediction of diarrheal infections (such as cholera, *Shigella* etc) remain a challenge even though disease causing pathogens are strongly associated with modalities of regional climate and weather system. Here we present an algorithm that integrates satellite derived data on several hydroclimatic and ecological processes into a framework that can determine high resolution cholera risk on global scales. Cholera outbreaks can be classified in three forms- epidemic (sudden or seasonal outbreaks), endemic (recurrence and persistence of the disease for several consecutive years) and mixed-mode endemic (combination of certain epidemic and endemic conditions) with significant spatial and temporal heterogeneity. Using data from multiple satellites (AVHRR, TRMM, GPM, MODIS, VIIRS, GRACE), we will show examples from Haiti, Yemen, Nepal and several other regions where our algorithm has been successful in capturing risk of outbreak of infection in human population. A spatial model validation algorithm will also be presented that has capabilities to self-calibrate as new hydroclimatic and disease data become available. We will also discuss how information on socio-economic status and human behavior influence public health decisions.

**S03.01.23. Advancing Extreme Heat Epidemiology Using Remotely Sensed Earth Observations: Generating a Long-Term Historical Time-Series of Daily Heat Metrics at the Community-Level**

Ambarish Vaidyanathan

*Ambarish Vaidyanathan*<sup>1</sup>

*1. National Center for Environmental Health, Centers for Disease Control and Prevention, Atlanta, GA, United States.*

Abstract: Epidemiologic studies exploring health impacts of extreme heat have relied on data from weather stations, which are limited in geographic scope. For this analysis, our objectives were to: (1) conduct a health assessment to evaluate differences in heat-attributable fractions (AFs) of mortality generated using temperature data from weather stations and earth observation based meteorological models; and (2) generate extreme heat metrics for CDC's National Environmental Public Health Tracking Network (Tracking Network). A daily time-series of heat metrics were created from weather stations and the North American Land Data Assimilation System Phase 2 (NLDAS) model. A county-specific time-series analysis was conducted for 2001-2015 using both station- and model-based data. The county-specific mortality risk information was pooled in a meta-analytic framework to characterize regional AFs for both station- and model-based data. Region-specific AFs were then compared to identify degrees of overlap and discrepancies between results generated using the two data sources. There is a high degree of overlap between region-specific AFs generated using temperature data from weather stations and the NLDAS model. AFs generated using NLDAS data provide robust inferences on region-specific differences in heat-mortality relationships as they include far more communities and not just those with weather stations. Extreme heat metrics from the NLDAS model were therefore generated for years 1979-2016, for every county and census tract in the coterminous U.S. Comprehensive spatiotemporal data coverage is a valuable attribute in public health. Disseminating model-based extreme heat metrics on CDC's Tracking Network could facilitate exposure ascertainment and health risk assessments at finer geographic scales.

### **S03.01.24. An Operational System for Surveillance and Ecological Forecasting of West Nile Virus Outbreaks**

Michael Wimberly

*Michael Wimberly<sup>1</sup>, Justin Davis<sup>1</sup>, Geoffrey Vincent<sup>1</sup>, Andrea Hess<sup>1</sup>, Michael Hildreth<sup>1</sup>*

*1. South Dakota State University, Brookings, SD, United States.*

Abstract: Mosquito-borne disease surveillance has traditionally focused on tracking human cases along with the abundance and infection status of mosquito vectors. Vector and host population dynamics are also sensitive to climatic factors, including temperature fluctuations and the availability of surface water for mosquito breeding. There is a potential to strengthen surveillance and predict future outbreaks by monitoring environmental risk factors using broad-scale sensor networks that include earth-observing satellites. The South Dakota Mosquito Information System (SDMIS) project combines entomological surveillance with gridded meteorological data from NASA's North American Land Data Assimilation System (NLDAS) to generate weekly risk maps for West Nile virus (WNV) in the north-central United States. Critical components include a mosquito infection model that smooths the noisy infection rate and compensates for unbalanced sampling, and a human infection model that combines entomological risk estimates with lagged effects of meteorological variables from the North American Land Data Assimilation System (NLDAS). Two types of forecasts are generated: long-term forecasts of statewide risk extending through the entire WNV season, and short-term forecasts of the geographic pattern of WNV risk in the upcoming week. Model forecasts are connected to public health actions through decision support matrices that link predicted risk levels to a set of phased responses. SDMIS accurately predicted higher-than-normal WNV transmission in 2016 and lower-than-normal transmission in 2017. Our experiences highlight several important lessons that can inform future efforts at disease early warning. These include the value of integrating climatic models with recent observations of infection, the importance of automated workflows to facilitate timely integration of multiple data streams, and the need to link forecasts with specific public health responses.

## S03.01G. Novel Methods for Assessing Exposure to Temperature and its Health Effects

### S03.01.25. Does Temperature Variability Modify Heat Impacts on Mortality? A Multi-City Multi-Country Study

Yuming Guo

*Yuming Guo<sup>1</sup>, Antonio Gasparrini<sup>2</sup>, Shanshan Li<sup>1</sup>, Shilu Tong<sup>3</sup>*

*1. Monash University, Melbourne, VIC, Australia.*

*2. London School of Hygiene and Tropical Medicine, London, United Kingdom.*

*3. Queensland University of Technology, Brisbane, QLD, Australia.*

**Abstract:** Background: There is increasing evidence that both temperature extremes and variability are risk factors for mortality. However, it is still unknown whether temperature variability is a modifier of the temperature-mortality relationship. Methods: We collected daily mortality and mean temperature from 511 communities in 28 countries/regions across the world. Temperature variability was calculated by the standard deviation of daily mean temperature at lags of 0-3 days. Community-specific time series model was used to examine the linear effect of heat (lag 0-3 days) on mortality in summer, while controlled for impacts of temperature variability and modelled their interaction on mortality. Random-effect meta-analysis was applied to summarise the city-specific associations. Results: The preliminary results of this study show that the effects of temperature on mortality were slightly higher when not controlling for temperature variability. For the interaction analysis, the lower the temperature variability, the higher the heat effects on mortality. However, the interaction effect was not statistically significant. At international level, each 5 celsius degree increase of temperature was associated with 2.8% (95% CI: 2.3%, 3.3%) increase of mortality in the first quartile of temperature variability, while there was 2.3% (95% CI: 1.8%, 2.8%) increase of mortality in the fourth quartile of temperature variability. The trends were similar for all cities/countries/regions, although there was significant variation in the heat impacts. Conclusion: The findings suggest no apparent need to control for temperature variability when modelling the heat effects on mortality. On behalf of the MCC Collaborative Research Network.

### **S03.01.26. Information on Exposure History Is Needed to Fully Understand Heat Effects on Elderly Mortality**

Hyun-Joo Bae

*Hyun-Joo Bae<sup>1</sup>, Giehae Choi<sup>2</sup>, Youn-Hee Lim<sup>3</sup>*

*2. University of North Carolina, Chapel hill, NC, United States.*

*3. SEOUL NATIONAL UNIVERSITY, SEOUL, Korea (the Democratic People's Republic of).*

**Abstract:** Background: Temperature change and extreme weather events caused by climate change are known risk factors to human health. Many studies have been conducted to understand the effects of climate change on adverse health outcomes. Objectives: We aimed to understand the relationship between elderly mortality and temperature anomaly using the Temperature Deviation Index (TDI), which considers exposure history. Methods: We assessed the effects of TDI on mortality in Korea from 1992 to 2015. The TDI was defined as the target day's temperature abnormality compared to previous 25 years' apparent temperature (AT). The relationship between the TDI and elderly mortality was examined by generalized linear modeling with Poisson distribution. Results: Most regions showed positive linear associations, and the associations ranged from 0.1% to 0.5% increase per unit increase of the TDI. Our analysis showed that increase in TDI was significantly associated with increase in elderly mortality in Korea. Conclusions: We suggest a positive and significant association between elderly mortality and temperature deviation index (TDI) an indicator representing abnormality of temperature using exposure history.

### **S03.01.27. Local Extreme Point Temperature and Mortality in Korea**

Youn-Hee Lim

*Youn-Hee Lim<sup>1</sup>, Chahng Woo Yi<sup>2</sup>, Youngjin Kim<sup>2</sup>, Hyuk Kim<sup>2</sup>, Yun-Chul Hong<sup>1</sup>, Seongwoo Park<sup>3</sup>, Hee Il Lee<sup>3</sup>*

- 2. Seoul National University, Seoul, Korea (the Republic of).*
- 3. Korea Centers for Disease Control and Prevention, Cheongju-si, Korea (the Republic of).*

**Abstract:** Background: Climate change has been issued because of its extreme patterns of temperature. We aimed to capture relatively extreme temperature within certain periods of time and associate it with health outcomes. Methods: We developed a novel method, Local extreme point temperature (LEP), to compare concurrent day's temperature with those in previous 3 days and determined whether it is a maximum value of temperature within the periods. We investigated the association between the LEP and cause-specific mortality (total, non-accidental, cardiovascular, ischemic heart disease, cerebrovascular, ischemic stroke, and haemorrhagic stroke) in 7 cities in Korea during 1992-2016. Using a time-series design, we estimated the percent change in mortality associated with the LEP after controlling for relevant covariates. Results: Total mortality increased by 1.8% (95% confidence intervals (CI), 1.3%, 2.3%) on days with the LEP compared to non-LEP days. The estimates were greater for cardiovascular mortality, 2.6% (95% CI, 1.1%, 4.2%), and ischemic stroke mortality, 3.0% (95% CI, 0.4%, 5.7%). Conclusion: Local extreme point temperature can be considered as an independent risk factor for mortality.

### **S03.01.28. Temperature Variability and Mortality in Urban and Rural China: An Application of Spatiotemporal Index**

Kejia Hu

*Kejia Hu<sup>1</sup>, Yuming Guo<sup>2</sup>, Xuchao Yang<sup>1</sup>, Jieming Zhong<sup>3</sup>, Fangrong Fei<sup>3</sup>, Feng Chen<sup>4</sup>, Qi Zhao<sup>2</sup>, Yunquan Zhang<sup>5</sup>, Shanshan Li<sup>2</sup>, Qian Chen<sup>1</sup>, Tingting Ye<sup>1</sup>, Jiaguo Qi<sup>1</sup>*

- 3. Zhejiang Provincial Center for Disease Control and Prevention, Hangzhou, China.*
- 4. Zhejiang Institute of Meteorological Sciences,, Hangzhou, China.*
- 5. Wuhan University, Wuhan, China.*

**Abstract:** Temperature variability (TV) is a potential trigger for death in urban areas, but there is little evidence of this in rural areas. In addition, a typical TV index only considers the temporal changes of temperature and ignores its spatial variability, which should be considered due to the effects of human mobility. In this study, we collected daily data on fine-gridded hourly temperatures and >2 million deaths that occurred in Zhejiang province, China from 2009 to 2015. A spatiotemporal TV index was developed by calculating the standard deviation of the hourly temperatures from multi-site records. A three-stage analysis was performed to estimate the mortality risks and mortality burdens of TV. Stratified analyses were performed by cause-specific mortality, urban/rural district, age and gender. Significant associations were found between TV and all types of targeted diseases, age groups, and genders. Percentage increase in mortality associated with a 1 °C increase in TV at 0-7 exposure days were found to be higher for rural dwellers than urban dwellers in the warm season [for all-cause mortality, 2.07% (95% CI: 1.49%, 2.64%) vs. 1.16% (95%CI: 0.70%, 1.62%)]. The elderly (aged 65+ years) and females were more sensitive to TV than young people and males, respectively. Additionally, we found that spatiotemporal TV produced higher mortality risks and larger attributable mortality fractions than typical TV indices. In summary, TV is an independent health risk factor. In China, rural areas generally suffer greater TV-related mortality risks than urban areas in the warm season. Overlooking spatial TV potentially underestimates the true effect of TV on mortality. These findings have important implications for developing area-, cause-, and group-specific adaptation strategies and emergency planning to reduce TV-related mortality.

## S03.01H. Science and Action for Safer Materials and Products

### **S03.01.29. Anticipating Impacts of Chemicals and Materials: Science for Context-Based Decisions**

Elaine Cohen Hubal

*Elaine Cohen Hubal<sup>1</sup>*

*1. US EPA, Research Triangle Park, NC, United States.*

**Abstract:** The landscape of consumer products is rapidly changing as novel chemicals and materials are designed and incorporated to enhance performance. Science and tools are needed to evaluate exposure and safety of chemicals and materials in the broader context of how these are used in our society. Scientifically sound approaches are required to increase the pace at which relevant information can be obtained and integrated into decision-making. A systems-, or context, based strategy for identifying and evaluating safer alternatives as well as ensuring that decisions minimize health risks and environmental impacts sustainably is proposed. Information and tools that are being developed to extend understanding of features and function to predict impacts under real-world conditions are highlighted. The views expressed in this paper are those of the authors and do not necessarily reflect the views of the US EPA.

### **S03.01.30. Policy Drivers for Safer Chemistry: Lessons Learned from a Review of Substitution Policies and Program Support Tools**

Molly Jacobs

*Joel Tickner<sup>1</sup>, Molly Jacobs<sup>1</sup>*

*1. Lowell Center for Sustainable Production, University of Massachusetts Lowell, Lowell, MA, United States.*

Abstract: Effectively mitigating the impact of toxic chemicals on human health and the environment requires not only taking regulatory action on chemicals of concern, but also supporting the informed transition to safer, alternative chemicals and technologies. Increased drivers for informed chemical substitution have led to a rapid evolution of substitution provisions within policies, as well as significant growth in alternatives assessment frameworks and methods. Nonetheless, most of these efforts are in their early stages. As part of an initiative to provide substitution policy and programmatic recommendations to government authorities, this project reviewed international substitution policies efforts and the availability of substitution assessment tools. Over 30 international regulatory and non-regulatory policies and programs that include informative substitution provisions were identified and analysed. In addition, four categories of alternatives assessment tools were reviewed, including chemical screening, comparative chemical hazard evaluation, economic and technical assessment, and frameworks for alternatives assessment. This presentation will describe notable findings from this review and elevate 5 primary elements that should be incorporated into the design and implementation of future substitution policies and associated support programs.

### **S03.01.31. Exposure Considerations Under California's Safer Consumer Product Regulations**

Meredith Williams

*Meredith J. Williams<sup>1</sup>*

*1. Safer Consumer Products, California Dept. of Toxic Substances Control, Sacramento, CA, United States.*

Abstract: The Safer Consumer Products (SCP) program is being implemented to reduce toxic chemicals in the products consumers buy and use. California's ground-breaking regulations identify specific products that contain potentially harmful chemicals and ask manufacturers to innovate and find safer alternatives. When deciding which products to prioritize, the department bases its decisions on chemical exposure potential and hazard potential. When selecting safer product designs or formulations, manufacturer decisions are also informed by the exposure pathways associated with those alternatives considered. This presentation describes the role of exposure science in informing California's policy and will discuss how tools such as conceptual models, dust studies, and near-field exposure models have been applied in SCP decision making. The presentation will highlight opportunities to address exposure-related information gaps to advance the search for alternatives.

### **S03.01.32. New Approaches to Prioritize Chemicals of Concern in Children's Products**

Marissa Smith

*Marissa N. Smith<sup>1</sup>, Faustman Elaine<sup>1</sup>*

*1. Environmental and Occupational Health Sciences, University of Washington, Seattle, WA, United States.*

Abstract: Predictive toxicology tools can be useful in prioritizing chemicals of concern found in children's consumer products. Traditional approaches for characterizing toxicity are laborious and do not cover the breadth of new and existing chemicals found in children's products. Recent regulations limiting the concentration of some toxic chemicals in children's consumer products have spurred the development of alternatives. However, it is challenging for traditional toxicity assessment approaches to keep up with the dynamic introduction of alternative chemicals. This presentation focuses on new predictive toxicology and chemical prioritization tools to help better characterize toxicity and exposure factors needed to make decisions that promote child health and development. Examples of chemical groups that will be discussed include engineered nanomaterials and phthalates. In vitro and in silico assessments can add valuable information to toxicity assessments, when appropriately interpreted. Examples of details needed for appropriate interpretation of in vitro assay results include cytotoxicity, dosimetry, chemical properties and binding patterns. Understanding what information is necessary to integrate new predictive toxicology tools and databases for prioritization of chemicals in children's consumer products within traditional toxicity assessments is important for identifying safer alternatives and promoting safe and sustainable children's products. In addition to available approaches we will also future directions and needs for chemical prioritization. This project is supported by the Environmental Protection Agency (FP-91779601-0, RD 83573801, RD 83451401) and the National Institute of Environmental Health Sciences (5P01ES009601).

## S03.01I. Translating Scientific Evidence About near Source Traffic Pollution Into Policy and Practice

### S03.01.37. Using Research on Traffic Pollution to Influence Policy and Practice

Doug Brugge

*Doug Brugge<sup>1</sup>, Alex Turner<sup>1</sup>, Lydia Lowe<sup>2</sup>, Ellin Reisner<sup>3</sup>, John Durant<sup>4</sup>, Wig Zamore<sup>3</sup>, Linda Sprague Martinez<sup>5</sup>*

- 1. Public Health, Tufts University, Boston, MA, United States.*

- 3. Somerville Transportation Equity Partnership, Somerville, MA, United States.*
- 4. Tufts University School of Engineering, Medford, MA, United States.*
- 5. Boston University School of Social Work, Boston, MA, United States.*

**Abstract:** Introduction: Community Assessment of Freeway Exposure and Health (CAFEH) is a series of community-based participatory research and translational projects in the Boston, MA area. CAFEH has used our air pollution exposure and epidemiology research to translate our findings and the broader literature into policy and practice at the neighborhood, municipal, metropolitan area and state level. Methods: To assess the impact of CAFEH, we conducted key informant interviews with people to whom we provided technical assistance (n=13). We asked about 1) their connection to CAFEH, 2) the ways in which CAFEH influenced their decision making, 3) the feasibility and acceptability of integrating protective measures against traffic pollution and 4) how they were using and disseminating knowledge they gained. Responses were recorded by note taking. Two researchers coded responses thematically by question and met to reconcile codes after which content analysis was applied. Results: Overall respondents had a favorable opinion of CAFEH. The most common impacts described were related to construction practices and the type of filtration used. Developers reported shifting building practices to use filtration above the industry standard. Policy makers described developing legislative proposals designed to reduce traffic-related exposures and attributed them directly to their work with CAFEH. Municipal planners said that working with CAFEH changed that way they think about community design so that they thought more about the health impacts of urban planning decisions. Overall, participants reported that what they learned continued to influence their decision-making for up to several years. It was also reported that engagement with CAFEH strengthened connections to the university. Conclusion: The CAFEH approach to CBPR has had modest, but real impact by actively translating our research and knowledge into policy and practice. Future efforts should attempt to expand the reach of these impacts.

### **S03.01.38. Global Goods Movement, Land-Use and Environmental Justice in Los Angeles, CA**

Jill Johnston

*Jill Johnston<sup>1</sup>, Rob McConnell<sup>1</sup>*

*1. Preventive Medicine, University of Southern California, Los Angeles, CA, United States.*

Abstract: The Trade Health and Environment (THE) Impact Project integrates science-based information and community-based action to ensure that reducing health, environmental, and community impacts of international trade becomes central to the transportation planning and urban design process in Los Angeles, California. Our academic- environmental justice partnership aims to shift the debate about transportation and health to elevate community voices in policymaking, while ensuring that advocates and policymakers use the latest science to inform their efforts. We will describe impacts of this action-oriented research, data collection and education, including regional and county-level policies on siting of schools near transportation corridors, adding high quality air filters to schools, using zero-emission technologies along goods movement corridors and halting the development of a massive diesel rail yard. In addition, there is a growing conflict between low-income housing needs and hazards of building along freeways. On-going efforts are underway to use the research to inform best practices and building codes at the City level if development is allowed very near freeways. Finally, we will share on-going efforts to re-envision urban design in urban environmental justice communities to secure healthy places for parks/green space, active transportation, and community gardens in cumulatively burdened neighborhoods.

### **S03.01.39. A Health Impact Assessment Study of the Barcelona 'superblock' Model**

Natalie Mueller

*Natalie Mueller<sup>1</sup>, David Rojas-Rueda<sup>1</sup>, Marta Cirach<sup>1</sup>, Joan Palou<sup>2</sup>, Salvador Rueda<sup>2</sup>, Mark Nieuwenhuijsen<sup>1</sup>*

*1. ISGlobal, Barcelona, Spain. 2. Agència d'Ecologia Urbana de Barcelona, Barcelona, Spain.*

**Abstract:** Background: Car-centric city designs of previous decades have resulted in sedentary lifestyles, high levels of environmental pollution and the disappearance of natural outdoor environments. The Barcelona 'superblock' model is a promising land-use strategy with the aim to reduce motor traffic while promoting active transport and returning public space to the citizens in order to promote social cohesion and healthy urban living. Methods: A health impact assessment (HIA) is carried out for 1,306,583 Barcelona residents  $\geq 20$  years assessing the health consequences of the projected superblock implementation with respect to expected changes in physical activity levels, air pollution, noise, local temperatures and access to green spaces. Preventable premature mortality, gains in life expectancy and economic impacts related to the superblock model are estimated. Results: With the implementation of the superblock model local traffic is expected to be reduced by 13%. Accordingly, current annual mean NO<sub>2</sub> levels of 46.2  $\mu\text{g}/\text{m}^3$  were estimated to be reducible to 35.2  $\mu\text{g}/\text{m}^3$  resulting in 506 preventable premature deaths (95% CI: 258-744) annually. Current annual mean Lden(Road) noise levels of 51.7 dB were estimated to be reducible to 48.3 dB resulting in 148 preventable premature deaths (95% CI: 75-223) annually. Temperature and green space analyses as well as evaluations of changes in life expectancy and economic impacts are still ongoing. Conclusions: The Barcelona superblock model is an encouraging land-use intervention with the aim to overcome contemporary burdensome motor traffic in cities and the associated physical inactivity crisis as well as environmental pollution burden. Associated health impacts are expected to make a case for the rapid implementation of this new urban model.

### **S03.01.40. Integrating Land Use and Transportation Advocacy with Environmental Health Science in Somerville MA U.S.A.**

Wig Zamore

*Wig Zamore<sup>1</sup>*

*1. Somerville Transportation Equity Partnership, Somerville, MA, United States.*

Abstract: Over several decades, activists in Somerville have worked to secure greater live work and green space balance, and healthier transportation alternatives, while also seeking to protect neighborhood character. We are a diverse median income community, next to booming Cambridge and Boston, with 60 languages spoken in our high school and less than 2 acres of public green space per 1000 residents. Per square mile, Somerville has 20,000 residents, mostly renters, and the state's greatest shortage of jobs relative to residents, and intensity of highway and diesel rail pollution. We have drawn on a history of environmental injustice and sought to expand our expertise in district design, planning, economic balance, transportation decision processes, and environmental health. Progress has been achieved via interaction with developers and government, litigation when necessary, and environmental health awareness. We have had some successes. Assembly Square, a large urban riverfront district planned to be big box retail and parking lots, is now redeveloping as a transit-oriented mixed-use district, with expanded riverfront green space and enhanced pedestrian and bicycle connections. It includes a developer funded subway stop, the first built in MA in three decades. It is also home to many new mixed income residents and the headquarters of PARTNERS Health, the largest hospital-based life sciences research group in the US. We have also secured state and Federal commitments to two new light rail branches, nearly half constructed, and completion of a transformative regional bike and path network. These projects represent over \$2 billion in new healthy transportation assets. Finally, working with Tufts and other research universities, we have advanced understanding of transportation pollution and cardiovascular risk, as well as mitigation tactics. Nevertheless, further integration of health and environment into all design scales remains challenging and critically important.

## 003.02A. Air Pollution, Atherosclerosis, and Cardiovascular Disease

### 003.02.01. Long-Term Effects of Air Pollution on Ankle-Brachial Index

Siqi Zhang

*Siqi Zhang<sup>1</sup>, Kathrin Wolf<sup>1</sup>, Susanne Breitner<sup>1</sup>, Florian Kronenberg<sup>2</sup>, Massimo Stafoggia<sup>3</sup>, Annette Peters<sup>1</sup>, Alexandra E. Schneider<sup>1</sup>*

*1. Institute of Epidemiology, Helmholtz Zentrum München, Munich, Germany.*

*2. Medical University of Innsbruck, Innsbruck, Austria.*

*3. Lazio Regional Health Service, Rome, Italy.*

**Abstract:** Background: Ankle-brachial index (ABI) has been linked to the risk of cardiovascular events. However, the association between long-term exposure to air pollution and abnormal ABI has not been fully investigated. Methods: This cross-sectional study involved 4,544 participants from the KORA Study (2004-2008) in the region of Augsburg, Germany. Participants' residential annual mean concentrations of particulate matter and nitrogen dioxide were predicted with land-use regression models, and the traffic information was collected from geographic information systems. We applied multinomial logistic regression models to assess the effects of air pollution on the prevalence of low and high ABI, and quantile regression models to explore the non-monotonic relationship between air pollution and ABI. Results: Long-term exposure to particulate matter with an aerodynamic diameter  $\leq 10 \mu\text{m}$  (PM<sub>10</sub>) and  $\leq 2.5 \mu\text{m}$  (PM<sub>2.5</sub>) was significantly associated with the prevalence of low ABI (ABI < 0.9), with the respective odds ratios (ORs) of 1.78 (95%CI: 1.09-2.92) and 1.63 (95%CI: 1.03-2.58) for an increment from the 5th to the 95th percentile in concentration. For high ABI (ABI > 1.3), the association was significant for PM<sub>2.5</sub> absorbance (OR = 1.54, 95%CI: 1.07-2.24) and traffic load within 100 m of the residence (OR = 1.39, 95%CI: 1.04-1.86). Quantile regression analyses revealed similar results. Conclusions: Long-term exposure to particulate matter and traffic-related air pollution was associated with higher prevalence of low and high ABI, respectively, indicating the adverse effects of air pollution on atherosclerosis and arterial stiffness in lower extremities.

### **003.02.02. Traffic-Related Air Pollution and Carotid Atherosclerotic Plaque Burden and Progression in London, Ontario, Canada**

Markey Johnson

*Markey Johnson<sup>1</sup>, Jeffrey R. Brook<sup>3</sup>, Robert D. Brook<sup>4</sup>, Tor H. Oiamo<sup>5</sup>, Isaac Luginaah<sup>7</sup>, Paul Peters<sup>6</sup>, J. David Spence<sup>2</sup>*

- 1. Air Health Science Division, Health Canada, Ottawa, ON, Canada.*

- 6. Department of Health Sciences, Carleton University, Ottawa, ON, Canada.*
- 7. Department of Geography, University of Western Ontario, London, ON, Canada.*

**Abstract:** The association between fine particulate matter (PM<sub>2.5</sub>) and cardiovascular disease (CVD) has been convincingly demonstrated. However, the role of traffic related air pollutants (TRAP) on CVD is less clear. To better understand the potential impacts of TRAP on CVD, we examined associations between nitrogen dioxide (NO<sub>2</sub>), carotid atherosclerotic plaque, and cardiometabolic disorders associated with CVD. Analyses were conducted among 2227 adult patients (63±14 years; 50% women) from the Stroke Prevention and Atherosclerosis Research Centre in London, Ontario, Canada. Total plaque area and progression, cardiometabolic disorders, and residential locations were obtained from medical records. Plaque was measured using 2-dimensional ultrasound. Plaque area progression was defined as an increase of > 5 mm<sup>2</sup> from baseline measurement. Outdoor residential NO<sub>2</sub> concentrations were generated by a land-use regression model. Associations between NO<sub>2</sub>, carotid plaque, and cardiometabolic disorders were examined using multiple linear regression models adjusted for age, sex, smoking, and socioeconomic status. Mean outdoor residential NO<sub>2</sub> concentration was 5.4 ppb (range: 3.0 to 13.0 ppb). NO<sub>2</sub> was associated with increased carotid plaque area and there was a positive interaction between NO<sub>2</sub>, smoking, and plaque progression (p<0.05). NO<sub>2</sub> was also associated with cholesterol and triglycerides (p<0.05), and marginally associated with diabetes. Diabetes mediated the relationship between NO<sub>2</sub> and plaque (p<0.05). Our results demonstrate for the first time that even low levels of TRAP exposure may be linked to atherosclerosis, an association which may be partially attributable to pollution-induced diabetes. Our results suggest that reducing ambient concentrations in cities with NO<sub>2</sub> below current standards would result in additional health benefits; and given the billions of people exposed to traffic emissions, our study supports the global public health significance of air pollution reduction.

### **003.02.03. Air Pollution and Subclinical Atherosclerosis in a Peri-Urban Area in South India (CHAI-Project)**

Cathryn Tonne

*3. Department of Non-communicable Disease Epidemiology, London School of Hygiene and Tropical Medicine, London, United Kingdom.*

Abstract: Previous studies linking particulate air pollution with carotid intima-media thickness (CIMT), a subclinical marker of atherosclerosis and predictor of cardiovascular events, have been conducted in high-income countries, with low or moderate levels of air pollution. We investigated the effect of ambient PM<sub>2.5</sub> and biomass fuel use on CIMT in a population-based cohort in peri-urban South India. We estimated annual average PM<sub>2.5</sub> outdoor at residence using land-use regression. Biomass cooking fuel was self-reported. Our exposures of interest were the mean and maximum CIMT, measured using a standardized protocol in the right common carotid during the third follow-up (2010-2012) of the APCAPS cohort. We fit a linear-mixed model including ambient PM<sub>2.5</sub> and biomass fuel use adjusting for potential confounders, in the whole population and stratified by sex. Models incorporated a random intercept for village, and a fixed effect for village-average PM<sub>2.5</sub>. Among 3278 participants (48% females, mean age 38 y), the mean PM<sub>2.5</sub> was 32.7 [range 24.4 to 32.2] µg/m<sup>3</sup>, 60% used biomass as their primary fuel, and the mean CIMT was 0.83 mm. We observed a positive association between within-village variation in PM<sub>2.5</sub> and mean CIMT in the whole population (+9.0% [-1.6, 19.5] per 5 µg/m<sup>3</sup> PM<sub>2.5</sub>) and among males (+14.9% [1.2, 26.6]). The effect of biomass compared to clean fuel (gas or electricity) was more pronounced among females, particularly among those without a stove vented to the outside (+6.1% [1.4, 10.9]). The effect of PM<sub>2.5</sub> was mainly driven by sub-groups with higher cardiometabolic risk profile. Results were robust to sensitivity analyses. We observed a strong association between ambient PM<sub>2.5</sub> and CIMT in a population with high prevalence of cardiovascular risk factors and higher levels of ambient air pollution than in the previous literature. Both ambient and household air pollution appear to contribute independently to atherosclerosis in this population.

### 003.02.04. Air Pollution Exposure and Progression of Atherosclerosis in Different Vessel Beds

**Abstract:** Background: Air pollution (AP) is an important environmental risk factor and atherosclerosis-based cardiovascular diseases are the leading cause of death in the westernized world. Epidemiological studies on the association of AP with atherosclerosis are scarce and inconsistent across different subclinical markers. We investigated AP effects (PM<sub>10</sub>, PM<sub>2.5</sub>, NO<sub>2</sub>) on progression of multiple subclinical markers of atherosclerosis (carotid intima media thickness (cIMT) and coronary/thoracic aortic calcification (CAC/TAC)). Methods: We used 5-year follow-up data from the German Heinz Nixdorf Recall cohort study (4814 participants aged 45-75 years at baseline (t<sub>0</sub>: 2000-2003)). Residential long-term exposure to PM<sub>10</sub>, PM<sub>2.5</sub>, NO<sub>2</sub> [µg/m<sup>3</sup>] was modelled via a chemistry transport model in 1x1km<sup>2</sup> grid cells. To harmonize progression of atherosclerosis among markers, progression was defined as any increase in side-specific cIMT (cIMTR, cIMTL [mm]) or CAC/TAC [Agatston score units] over 5 years. Using confounder-adjusted logistic regression, we calculated odds ratios (OR (95%-confidence intervals)) in the full sample, in participants with no (cIMT<sub>t0</sub><0.7mm, or CAC<sub>t0</sub>=0, TAC<sub>t0</sub>=0) or low (CAC<sub>t0</sub><10, TAC<sub>t0</sub><10) degree of subclinical atherosclerosis at baseline. Results: While no associations were observed in the full sample, AP was associated with progression in participants free of subclinical atherosclerosis at baseline, e.g. a 5 µg/m<sup>3</sup> increase in PM<sub>10</sub> yielded an OR of 1.7 (1.1, 2.6) for cIMTL, and 1.3 (1.0, 1.7) and 1.3 (0.9, 1.9) for incident CAC and TAC. For CAC<sub>t0</sub>/TAC<sub>t0</sub><10, estimated ORs were 1.2 (0.9, 1.4) for CAC, 1.1 (0.8, 1.3) for TAC. A 5 µg/m<sup>3</sup> increase in NO<sub>2</sub> yielded slightly weaker results, e.g. 1.3 (1.0, 1.6) for cIMTL. There was no evidence for progression in CIMTR with any investigated air pollutant. Conclusion: Results indicated air pollution effects on progression of atherosclerosis in three out of four vessel beds in participants with no degree of atherosclerosis at baseline.

### **003.02.05. Residential Ambient Particulate Air Pollution and Blood Pressure in Peri-Urban India**

**Abstract:** Long-term exposure to ambient fine particulate matter (PM<sub>2.5</sub>) has been linked to high blood pressure in high-income countries. However, it is unclear if these findings are generalizable to low- and middle-income countries, which may have higher PM<sub>2.5</sub> levels dominated by different and mixed sources. We examined cross-sectional associations between annual residential ambient PM<sub>2.5</sub> and black carbon (BC) levels with systolic blood pressure (SBP) and diastolic blood pressure (DBP) in adults living in a peri-urban area outside of Hyderabad, India. Blood pressure was measured in the right arm after 5 minutes of sitting rest using an oscillometric device. Annual averages of PM<sub>2.5</sub> and BC at residence were estimated using land-use regression models. Participants (N=5,531, 18-84 years, 54% men) lived in 2,296 households across 28 villages. We used nested linear mixed-effect models (households nested within villages) stratified by sex to estimate associations between within-village differences in PM<sub>2.5</sub> or BC and SBP and DBP. Annual average PM<sub>2.5</sub> was 32.8 µg/m<sup>3</sup> (SD=2.7) and BC was 2.5 µg/m<sup>3</sup> (SD=0.2). In women, SBP increased by 1.47 mm Hg (95%CI, 0.21 to 2.74) per 1 µg/m<sup>3</sup> increase in PM<sub>2.5</sub> after adjusting for personal, household, and environmental confounders. Results were weaker and not statistically significant in men, for DBP, and for BC (in both men and women). Adjustment for cooking fuel did not change the results. Our study provides support for an association between ambient PM<sub>2.5</sub> and SBP in women, independently of the type of cooking fuel. Further research focusing on personal exposure and using longitudinal designs is needed to provide valuable insights into the relationship between particle exposure and blood pressure in populations exposed to relatively high ambient concentrations, such as those present across much of India.

### **O03.02.06. Personal Ozone Exposure, Blood Pressure and Vascular Endothelial Function: A Panel Study Based on Cytokines, DNA Methylation and Metabolomics**

Renjie Chen

*Renjie Chen<sup>1</sup>, Yongjie Xia<sup>1</sup>, Yue Niu<sup>1</sup>, Jing Cai<sup>1</sup>, Haidong Kan<sup>1</sup>*

*1. Fudan University, Shanghai, China.*

**Abstract:** Background: Epidemiological studies have reported inconsistent findings on the cardiovascular effects of exposure to ambient ozone. There is a lack of molecular epidemiological studies of ozone based on personal real-time monitoring. Objective: To explore the impacts of personal ozone exposure on blood pressure and vascular endothelial function. Methods: We conducted a longitudinal panel study with 4 follow-ups among 40 college students in Shanghai, China, during the warm period of 2016. We measured in real time personal ozone exposure levels and serum angiotensin-converting enzyme (ACE) and endothelin-1 (ET-1), locus-specific methylation of ACE and ET-1. We also used an untargeted metabolomic approach to systemically evaluate the vascular effects of ozone. We applied linear mixed-effects models to examine the effects of ozone on blood pressure (BP), ACE, ET-1, DNA methylation and metabolites. Results: An interquartile range (IQR, 47.58  $\mu\text{g}/\text{m}^3$ ) increase in 2 hours' ozone exposure was significantly associated with increments of 1.77mmHg in systolic BP and 1.69 mmHg in diastolic BP. Simultaneously, there were increases of 5.20% in ACE and 0.48% in ET-1. DNA methylation of the two cytokines decreased following ozone exposure. An IQR increase in ozone concentrations (0-8 h) was significantly associated with 0.20 % decrease in locus-average ACE methylation. The inverse association between ozone exposure and ET-1 methylation only occurred in one locus. Metabolomic analysis showed meaningful changes following ozone exposure in serum lipid metabolites in relation to vascular endothelial dysfunction. Conclusions: Our findings highlighted a potential mechanistic pathway linking acute ozone exposure to increased blood pressure and vascular endothelial dysfunction.

## 003.02B. Air Pollution, Fetal Growth, and Birth Outcomes

### **003.02.07. The Effects of Prenatal Exposure to PM<sub>2.5</sub> on Fetal Growth: Evidence from a Birth Cohort Study in China**

Tao Liu

*Tao Liu<sup>1</sup>, Li Fu<sup>1</sup>, Xinyi Yang<sup>1</sup>, Wenjun Ma<sup>1</sup>*

*1. Guangdong Provincial Center for Disease Control and Prevention, Guangzhou, China.*

**Abstract:** Objectives: We aimed to investigate the effects of PM<sub>2.5</sub> exposure on fetal growth, and further clarify the susceptible exposure window based on a birth cohort in China. Methods: Pregnant women who had their prenatal care in the first trimester were recruited in the obstetrical clinics, and were followed up till their delivery time. Their personal information was collected by questionnaire, and their clinical information was obtained through their medical records. Each participant's individual exposure to PM<sub>2.5</sub> during the pregnancy was assessed using an spatio-temporal modelling that integrated a land-use-regression model and individual activity pattern. Results: A total of 2,845 pregnant women were recruited in this study, with an average age of 31 years. The average PM<sub>2.5</sub> exposure during the entire pregnancy was 31.14µg/m<sup>3</sup>. The results of multiple linear regression analyses show that after adjustment for potential confounding factors each 10µg/m<sup>3</sup> increase in PM<sub>2.5</sub> exposure during the first trimester was associated with 1.55cm decrease in crown heel length in the first trimester, and 0.17cm less in birth length. Each 10µg/m<sup>3</sup> increase in PM<sub>2.5</sub> exposure during the second trimester was linked to decreases in head circumference, abdomen circumference, biparietal diameter and femur length by 2.38cm, 2.05cm, 0.90cm and 1.12cm, respectively. However, the PM<sub>2.5</sub> exposure during the third trimester was associated with increase in birth length by 0.16cm. Conclusions: Prenatal exposure to PM<sub>2.5</sub> may be an important risk factor of fetal growth. The first and second trimesters might be the sensitive exposure window. Our findings added new information, and extended our understanding of the risk factors of fetal growth. More studies are needed to explore the mechanisms of PM<sub>2.5</sub> affecting fetal growth

### **003.02.08. Spatiotemporal Variations of Maternal Exposures to Air Pollution and Risks of Adverse Birth Outcomes in Lanzhou, China**

Lan Jin

*Lan Jin<sup>1</sup>, Qing Liu<sup>3</sup>, Yaqun Zhang<sup>4</sup>, Jie Qu<sup>3</sup>, Yawei Zhang<sup>2</sup>, Michelle Bell<sup>1</sup>*

*3. Gansu Provincial Maternity and Child Care Hospital, Lanzhou, China.*

*4. Gansu Academy of Environmental Sciences, Lanzhou, China.*

**Abstract:** Previous studies indicated associations between air pollution and adverse birth outcomes, but results were inconclusive. Different exposure assessment methods might contribute to this apparent inconsistency. The objective of this study is to estimate maternal exposures to air pollution using exposure assessment methods with various spatiotemporal resolutions, and related risks of adverse birth outcomes in Lanzhou, China. The study population is 8087 singleton live births with maternal and work addresses in Lanzhou urban area. Exposures during entire pregnancy were estimated for PM<sub>10</sub>, PM<sub>2.5</sub> and NO<sub>2</sub>, using land use regression (LUR) models or government monitoring data. Spatial exposure variables were developed: road densities, industrial areas near residence and proximity to major point sources. Logistic or linear regression models were used to investigate associations of maternal exposures with risks of congenital heart defect (CHD), preterm birth (PTB), low birth weight (LBW), or change in birth weight. Models were adjusted for maternal social economic status and risk factors. Risks were estimated for interquartile range increases of exposure variables. Clusters of adverse birth outcomes occurred in the west of the city, where major point sources were concentrated. Maternal exposures to PM<sub>10</sub> were significantly associated with increased CHD risks (OR: 2.23, 95% CI: 1.38, 3.58) and reduced birth weight (-21.1 g, 95% CI: -38.5, -3.6 g). Proximity to major point sources marginally elevated LBW risks (OR: 0.82, 95% CI: 0.67, 1.00). Effect estimates based on LUR-modeled exposures were more certain than those based on government monitors. Maternal exposures to particles were associated with increased risks of adverse birth outcomes in Lanzhou, which has major point sources. Studies investigating air pollution exposures and related health risks at high spatiotemporal resolutions is valuable for disentangling health effects of different air pollutants or pollution sources.

**Abstract: Background/Aims:** Exposure to fine particulate matter of <2.5mm (PM2.5) during pregnancy is associated with adverse birth outcomes, including miscarriage and birth defects. There is a pressing public health need to better understand the impact of such exposures. Here, we analysed the effects of pre-pregnancy and in utero PM2.5 exposure upon the risk of pre-term births by its timing and intensity. **Methods:** We used data from 10,306 live births within Project ELEFANT, a multi-cohort study based in Tianjin, China. Data on pre-term births (n=220) was recorded by obstetricians. Hourly air pollution measured by local ambient monitoring stations was averaged for the exposure period and used to calculate the number of days individuals were exposed to PM2.5 levels over 50, 100, 150, 200, 250 and 300µg/m<sup>3</sup> by month/trimester. We used generalized additive models to represent the non-linear relationship between outcome and spatio-temporal varying PM2.5 exposure. Models were adjusted for maternal age, education & occupation, neonate gender, region, paternal smoking, gravidity, parity, and mean temperature & dew point of the exposure period. **Results:** Risk of pre-term birth increased with higher frequency of extreme PM2.5 exposure in the final month of pregnancy. Relative risks (RR) ranged from 1.04 (95% CI: 1.00-1.07) with increased exposure to >50µg/m<sup>3</sup> PM2.5 to 1.53 (1.32-1.79) with exposures to >250µg/m<sup>3</sup>. Higher risk was also observed with increased exposure to >250µg/m<sup>3</sup> in the second- (1.19, 1.02-1.40) and third-last months of pregnancy (1.47, 1.30-1.67). Further, the RR of pre-term birth was 1.67 (1.40-1.99), 1.65 (1.32-2.07) and 1.57 (1.27-1.94) with increased exposure to >250µg/m<sup>3</sup> PM2.5 in the first-, second- and third-months before pregnancy respectively. **Conclusions:** Our findings reveal that the level and timing of PM2.5 exposure are critical in establishing the risk of pre-term birth. Further work is required to elucidate their associations with birthweight and birth defects.

### **003.02.10. Exposure-Lag-Response Association between Prenatal Ambient Air Pollution Exposure and Preterm Birth in Guangzhou, China**

Qiong Wang

*3. School of Public Health, The University of Queensland, Herston, QLD, Australia.*

Abstract: Prenatal trimester-specific air pollution exposure has been associated with preterm birth (PTB), however, little is known about the effects of gestational week specific exposure on PTB and critical exposure windows are still unclear. Using data from the Guangzhou Birth Registry including 506,210 singleton live births between January 2015 and July 2017, we assessed the susceptible exposure windows during pregnancy at weekly level. Daily average concentrations of PM<sub>2.5</sub>, PM<sub>10</sub>, NO<sub>2</sub>, SO<sub>2</sub>, and O<sub>3</sub> from 11 monitoring stations were used to estimate district-specific exposures for each participant based on residential addresses during pregnancy. Distributed lag models (DLMs) were applied to estimate the association between weekly-specific maternal air pollutant exposures and PTB, after controlling for temperature, seasonality, and individual covariates. Hazards ratios (HRs) and 95% confidential intervals (95%CIs) were calculated for an interquartile range (IQR) increase in air pollutants during the study period. Multi-pollutant models were also performed. PTB risk was significantly associated with PM<sub>2.5</sub> exposure during the 17th to 25th gestational week, with the strongest effect in the 22nd gestational week (IQR=27.0 ug/m<sup>3</sup>; HR=1.04, 95%CI:1.02-1.06). The significant exposure windows were 14th-30th gestational weeks for PM<sub>10</sub>, 9th-27th for NO<sub>2</sub>, and 19th-28th for O<sub>3</sub>, respectively. Corresponding peak associations were observed in the 25th gestational week for PM<sub>10</sub> (IQR=37.0 ug/m<sup>3</sup>; HR=1.04, 95%CI:1.02-1.05), in the 22nd for NO<sub>2</sub> (IQR=29.0 ug/m<sup>3</sup>; HR=1.03, 95%CI:1.02-1.05), and in the 24th for O<sub>3</sub> (IQR=90.0 ug/m<sup>3</sup>; HR=1.06, 95%CI:1.04-1.08). No significant association between pregnancy SO<sub>2</sub> exposure and PTB was observed. In multi-pollutant models, effects of each pollutant retained but were slightly reduced. Our results suggest critical air pollution exposure windows for PTB risk vary slightly among air pollutants, while the mid-gestation was similarly observed as a susceptible period.

### **O03.02.11. Exposure to PM2.5 and Risk of Pre-Term Birth: Applying Distributed Lag Non-Linear Models to Disentangle Complex Exposure-Lag-Response**

Andreas Neophytou

*Andreas M. Neophytou<sup>1</sup>, Sadie Costello<sup>1</sup>, Amy M. Padula<sup>2</sup>, Wei Yang<sup>3</sup>, Frederick Lurmann<sup>4</sup>, S. Katharine Hammond<sup>1</sup>, Ellen A. Eisen<sup>1</sup>, Gary Shaw<sup>3</sup>*

*4. Sonoma Technology Inc, Petaluma, CA, United States.*

**Abstract:** Evidence in the literature suggests an association between maternal exposure to air pollution during pregnancy and increased risk of pre-term birth. Assessing exposure effects occurring over the duration of pregnancy can be challenging, as timing, intensity and duration of exposure could all be biologically relevant. Cumulative exposure or trimester averages assume a constant lag-response over the duration of pregnancy or trimesters, respectively, and may not fully capture true relationships. In this study we applied distributed lag non-linear models (DLNM) within a survival analysis, in order to better examine the exposure-lag-response between average weekly PM2.5 exposure during gestation and risk of pre-term birth. We analyzed data from all live births with PM2.5 data on the week level (n=79,119) in Fresno County, California, from 2000 to 2006. We fit pooled generalized additive logistic models to approximate hazard ratios (HR), adjusting for gestational age, calendar time, temperature, mother's race/ethnicity, education, age and socioeconomic status. Our results indicate increased risk of pre-term birth associated with exposure during a lag-window of 0-20 weeks prior to the week at risk, with higher risk between lags 7-15. For the majority of cases the latter lag-window occurred within the second trimester of pregnancy. Non-linearity in the exposure-response was also observed with steeper relative increase in the hazard at lower ranges of the observed exposures. The HR for pre-term birth at 35 weeks of gestation corresponding to an increase from 13.6 µg/m<sup>3</sup> (the median of the observed exposures) to 18.6 µg/m<sup>3</sup>, for the duration of the second trimester of pregnancy was 1.45 (95%CI: 1.11,1.91). Our results suggest that both timing and intensity of exposure are contributing factors to the overall exposure-lag-response. The flexibility allowed by DLNMs could benefit studies of exposures accrued over the duration of pregnancy in relation to pregnancy related outcomes.

Abstract: There is growing evidence on the association between prenatal metal exposures and adverse pregnancy outcomes. Heavy metals such as arsenic (As), cadmium (Cd), mercury (Hg) and lead (Pb) are considered as endocrine disrupting chemicals and elevated exposure to these metals during pregnancy is associated with adverse effects on maternal and infant health. Nevertheless, mechanistic understanding is required to establish biological plausibility of such associations. The objective of this study was to gain insight into metal exposure-related adverse birth outcomes by understanding maternal systemic changes at the molecular level. The Maternal-Infant Research on Environmental Chemicals (MIREC) study was employed for this purpose. Third trimester maternal plasma samples were analysed for target oxidative /nitrative stress markers (e.g 8-isoprostane, 3-nitrotyrosine) by competitive enzyme immunoassay and HPLC-Coularray as well as matrix metalloproteinases, a class of enzymes and other markers of inflammation (e.g. Cytokines, cellular adhesion molecules) were measured by affinity-based multiplex array and HPLC-Fluorescence detection methods. Pearson product moment correlations, chi-squared tests and multivariate models were used to analyse the associations among maternal blood metal (Cd, Hg, Pb, As, manganese Mn) levels, plasma biomarkers, physiological changes and birth weight. Our results revealed maternal metal exposure-specific responses ( $p < 0.05$ ) on markers of oxidative stress pathways (e.g 8-isoprostane) and matrix metalloproteinases (MMPs), in maternal circulation. Interestingly, statistically significant ( $p < 0.05$ ) correlations were seen between oxidative stress pathways, MMPs and other inflammatory mediators relevant to infant birth weight changes. Our findings imply that metal exposures potentially can mediate maternal oxidative stress pathways which can alter MMP profiles and associated inflammatory processes, thus adversely impacting on infant birth weights.

**O03.02.13. Benefits of Personal Modeling for Air Pollution Exposure Assessment**

David Donaire-Gonzalez

*David Donaire-Gonzalez<sup>1</sup>, Roel Vermeulen<sup>1</sup>*

*1. Institute for Risk Assessment Sciences , Utrecht, Netherlands.*

Abstract: There is a need to move from static (residential) to dynamic (personal) estimates to assess an individual's air pollution exposure. However, data is limited on the added value of dynamic exposure modeling versus estimates based on residential address commonly used in health studies. We built personal exposure estimates of particulate air pollution (PM<sub>2.5</sub> and soot; PM<sub>10</sub>) and compared it to personal measurements as well as residential ambient estimates. Forty two participants were monitored for 24 hours three non-consecutive times. Participants were equipped with a smartphone and a gravimetric sampler. Personal measurements of PM<sub>2.5</sub> and PM<sub>10</sub> were obtained with a microbalance of 1µg accuracy and a Smoke Stain Reflectometer, respectively. The dynamic model integrates: (i) smartphone time-resolved geo-location; (ii) time in micro-environments from a spatiotemporal map-matching algorithm; (iii) an outdoor/indoor penetration factor; (iv) land-use regression models for PM<sub>2.5</sub> and PM<sub>10</sub>; and (v) government monitoring stations. Residential estimates were computed combining home geo-location with land-use regression estimates adjusted temporally by the daily ratio of the closest monitoring station. A total of 123 measurements were obtained. The median and interquartile range of personal exposure measurements was 9 (7.6) µg/m<sup>3</sup> for PM<sub>2.5</sub> and 0.8 (0.7) 10<sup>-5</sup>/m for PM<sub>10</sub>. The agreement (Concordance Correlation Coefficient) between personal measures and personal and residential estimates were respectively 0.58 (0.45 - 0.69) and 0.43 (0.32 - 0.53) for PM<sub>2.5</sub>, and 0.55 (0.41 - 0.67) and 0.48 (0.35 - 0.59) for PM<sub>10</sub>. The dynamic model improves the concordance with personal measurements by 38% and 15% as compared to the static estimates of PM<sub>2.5</sub> and PM<sub>10</sub>, respectively. Applying dynamic models may provide a way forward to obtain more valid individual estimates of ambient air pollution exposure.

### **003.02.14. Field Experience with a Commercial Biometric Shirt for Measuring Minute Ventilation and Potential Inhaled Dose of Air Pollutants**

Steven Chillrud

*Steven Chillrud<sup>1</sup>, Qiang Yang<sup>1</sup>, Cara Smith<sup>1</sup>, Aimee Layton<sup>2</sup>, James Ross<sup>1</sup>, Jonathan Thornburg<sup>3</sup>, Patrick Kinney<sup>4</sup>, Richard Sloan<sup>5</sup>, Darby Jack<sup>6</sup>*

**Abstract:** Real-time estimates of volumetric minute ventilation (MV) can now be made through wearable sensors, allowing field studies to extend the personal exposure approach to more accurately account for impact of physical activity and calculation of the potential inhaled dose (PID) or intake of air pollutants. The Hexoskin biometric shirt includes sensors for all three proxy methods for estimating minute ventilation: dual band respiratory inductance plethysmography (RIP), heart rate (HR) and accelerometry (ACC). Laboratory validation of the sensors against a gold standard has been reported on previously. Here we will provide our experience in an ongoing field study of biking commuters who self-deploy the shirt and additional monitors for up to six 24 hour periods over a 3 week period. Data completeness from the biometric shirt sensors is high with only 6 out of 327 attempted sessions missing data (2%); within the obtained data, the percentage with valid data are 89% for the dual band RIP sensors, 80% for the HR monitor and 88% for the ACC. Poorly fitting shirts can impact the RIP or HR sensors (or both), with poor fits occurring more frequently on females. Failure of all three sensors simultaneously is rare allowing missing data to be filled in from other working sensors based on individual level comparisons. MV values during sleep appear anomalously low for a large fraction of participants (median 5.0 L/min, IQR 3.6 - 7.0 L/min) and 0.06% of RIP derived values appear above physiological reasonable values, leading to the use of replacement values. Final cleaned MV data derived from the shirt show a much wider range, both between subjects and within subjects, than the EPA reference values, suggesting exposure misclassification can occur if relying upon reference values for calculating PID.

### **O03.02.15. Assessment of Microenvironmental Exposures to Ultrafine Particles among Adolescent Schoolchildren**

Christopher Wolfe

*Christopher Wolfe<sup>1</sup>, Haley M. Beavers<sup>1</sup>, Cole Brokamp<sup>1</sup>, Patrick Ryan<sup>1</sup>*

*1. Div. Biostatistics and Epidemiology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, United States.*

**Abstract:** Background: Assessing personal exposure to ultrafine particles (UFPs) is challenging due to multiple indoor and outdoor sources and high spatiotemporal variation. Our objective is to characterize personal UFP exposures experienced by adolescents enrolled in the Ecological Momentary Assessment and Personal Particle Exposure Study (EcoMAPPE). Methods: Participants (ages 13-17) complete a seven-day sampling period using a personal UFP monitor for 3 hours each day that simultaneously records GPS-based location at 1-second resolution. Measured UFP concentrations are assigned to microenvironments based on speed and distance from participant specified locations: schools (400m), homes (100m), and other (100m) locations. UFP concentrations measured outside these areas exhibiting speeds greater than 2 m/s are categorized as occurring while in transit. We define the percent contribution of each microenvironment to a participant's overall exposure as the summation of UFP concentration in a specific microenvironment divided by the summation of all recorded UFP concentrations. Lastly, we derive exposure-time ratios by dividing the percent contribution of each microenvironment by the percentage of time spent within each microenvironment. Results: Complete sampling and location data is available for 21 participants, representing 378.5 hours of UFP data. The overall median UFP concentration is lowest at home (4,500 particles/cm<sup>3</sup>), while school/other (5,990), and transit concentrations (7,960) are higher. Most UFP measurements are recorded at home (70%), followed by school/other locations (23%), and transit (7%). Participants experience median exposure-time ratios of 0.99 (Q1: 0.90; Q3: 1.04) at home, 0.82 (0.45; 1.21) at other locations, and 1.10 (0.62; 1.73) in transit. Conclusion: Despite the low percentage of time spent in transit, most participants experience UFP concentrations during transit that contribute more to their overall exposure in comparison to other microenvironments.

### **003.02.16. The Influence of Residential and Workday Population Mobility on Exposure to Air Pollution in the UK**

Stefan Reis

Abstract: Traditional approaches of quantifying population-level exposure to air pollution assume that concentrations of air pollutants at the residential address of the study population are representative for overall exposure. This introduces potential bias in the quantification of human health effects. Our study combines new UK Census data comprising information on workday population densities, with high spatio-temporal resolution air pollution concentration fields from the WRF-EMEP4UK atmospheric chemistry transport model, to derive more realistic estimates of population exposure to NO<sub>2</sub>, PM<sub>2.5</sub> and O<sub>3</sub>. We explicitly allocated workday exposures for weekdays between 8:00 am and 6:00 pm. Our analyses covered all of the UK at 1 km spatial resolution. Taking workday location into account had the most pronounced impact on potential exposure to NO<sub>2</sub>, with an estimated 0.3 mg m<sup>-3</sup> (equivalent to 2%) increase in population-weighted annual exposure to NO<sub>2</sub> across the whole UK population. Population-weighted exposure to PM<sub>2.5</sub> and O<sub>3</sub> increased and decreased by 0.3%, respectively, reflecting the different atmospheric processes contributing to the spatio-temporal distributions of these pollutants. We also illustrate how our modelling approach can be utilised to quantify individual-level exposure variations due to modelled time-activity patterns for a number of virtual individuals living and working in different locations in three example cities. Changes in annual-mean estimates of NO<sub>2</sub> exposure with inclusion of workday location are considerably higher than the population average. Conducting model-based evaluations as described here may contribute to improving representativeness in studies that use small, portable, automatic sensors to estimate personal exposure to air pollution.

### **O03.02.17. Mitigation of Commuter's Air Pollution Exposure Via Personal Choices: Exploring Exposure Metrics**

Nicholas Good

*2. Johns Hopkins, Baltimore, MD, United States.*

**Abstract:** In the developed world some of the highest air pollution exposures are experienced when commuting on roadways. Choice of route and transit mode have implications for the harmful dose of air pollution received; however, few studies have assessed how these factors influence exposure in real-world settings. In this study, we quantified the differences in cyclists' and drivers' air pollution exposure accounting for inhalation and commute duration under realistic conditions and assessed whether pollution intake can be changed by choice of route and mode. Personal exposure to black carbon (BC), carbon monoxide (CO), PM<sub>2.5</sub> (the mass of particles < 2.5µm in diameter), and particle number (PN) were measured for 45 commuters over approximately 700 commutes. Each commuter drove and cycled to and from their workplace via direct and alternative routes designed to lower exposure levels. Commuter's inhalation was modeled using their measured heart rate and physiological variables. Differences in commuter's mean exposure levels (when comparing combinations of various route/mode choices for the four pollutants) ranged from -66% to 96% and were strongly impacted by differences in their minute ventilation rate and trip duration. On comparable direct routes cyclists inhaled: 460% [95% Confidence Interval (CI): 306%, 638%] more BC, 98% [95% CI: 38%, 173%] more CO, 727% [95% CI: 435%, 1073%] more PM<sub>2.5</sub>, and 552% [95% CI: 263%, 1010%] more PN than when driving. On routes designed to avoid traffic cyclists saw reductions in the amount of pollution they inhaled: -36% [95% CI: -53%, -8%] less BC, -44% [95% CI: -63%, -15%] less CO, -26% [95% CI: -53%, 15%] less PM<sub>2.5</sub>, and -9% [95% CI: -46%, 62%] less PN compared to cycling directly along larger roads. These results suggest a fraction of the additional air pollution inhaled when cycling compared to driving can be mitigated by choice of route in a mid-sized city.

**003.02.18. Personal Exposures to Ambient Particulate Matter (PM) Versus Ambient PM Concentrations as a Metric for the Relationship of Daily Cardiovascular Mortality with Daily Air Pollution (Phoenix, AZ, 1957-1958)**

William Wilson

*William E. Wilson<sup>1</sup>*

*1. Retired from US EPA, Chapel Hill, NC, United States.*

Abstract: The amount of ambient PM found indoors is less than the ambient PM concentration. Since people spend much of their time indoors, the ambient concentration (AC) will be a noisy surrogate for personal exposure to ambient (PEA). In this paper, we will estimate the average daily personal exposure to both PM<sub>2.5</sub> and PM<sub>10-2.5</sub> and use this time series to estimate the relationship between daily PEA and daily cardiovascular mortality (CVM). We will compare these relationships with those found for AC and CVM. For a house with windows closed and few openings of doors, the air exchange rate,  $a$ , depends on the temperature difference between indoors and outdoors. From the literature,  $a=0.176+0.0162\bullet\Delta T(\text{OC})$ , based on daily measurements for a year. The ratio of the indoor concentration of an ambient air pollutant to the concentration of that ambient air pollutant outdoors, the infiltration factor, is given by  $P a/a+k$  where  $P$  is the penetration efficiency and  $k$  is the deposition rate. From the literature we have  $k(\text{PM}_{2.5})=0.39$ ,  $k(\text{PM}_{10-2.5})=1.01$  and  $P=1$  for both.  $\Delta T$ =the absolute value of the difference between the average daily temperature and an estimated indoor temperature of 21.1°C (70°F). We can now estimate the daily, community-average, indoor concentrations of PM and use these values as surrogates for PEA. For a city like Phoenix, where >99% of the homes are air-conditioned, and using CVM of people  $\geq 65$ , the indoor concentration should be a reasonable surrogate for PEA. Results will compare betas, t-statistics, and % Increases in Risk with  $\pm 95\%$  CI for individual lag days out to lag day 10 and for a combined beta for all lag days with  $t>0.5$  for both PMs. The relationship with AC is useful because air quality standards are based on ambient concentrations. However, PEA gives greater betas and greater statistical significance, supporting the importance of air pollution as a health hazard. For the same personal exposures, PM<sub>2.5</sub> and PM<sub>10-2.5</sub> are equally hazardous.

## 003.02D. Geographic Location and Cancer

### **003.02.19. Arsenic and Bladder Cancer: Very High Mortality Continues >50 Years after First High Exposure**

Taehyun Roh

*Taehyun Roh<sup>1</sup>, Craig Steinmaus<sup>1</sup>, Guillermo Marshall<sup>2</sup>, Catterina Ferreccio<sup>2</sup>, Jane Liaw<sup>1</sup>, Allan Smith<sup>1</sup>*

*2. Pontificia Universidad Católica de Chile, Santiago, Chile.*

**Abstract: Background/Aim:** The city of Antofagasta, the major city in northern Chile, had a specific period (1958-1970) with very high arsenic water concentrations of around 870 ug/L. We previously reported increased mortality associated with this arsenic exposure for 1981-2000, and separately for 2001-2010. In this paper, we compare bladder cancer mortality in Antofagasta with the that of the rest of Chile between these two periods. **Methods:** The age and gender specific numbers of bladder cancer deaths in Antofagasta were compared with expected numbers based on the rest of Chile for the two periods 1989-2000 and 2001-2010, and Standardized Mortality Ratios (SMRs) and attributable risks were estimated. We also made comparisons between different birth cohorts. **Results:** The overall SMRs for bladder cancer for Antofagasta were 8.8 (95% CI, 7.9-9.8) in 1989-2000, and 6.2 (95% CI, 5.6-6.9) in 2001-2010. The attributable risks among the exposed were 89% and 84%, with 296 bladder cancer deaths attributable to arsenic in the period 1989-2000, and 280 in the period 2001-2010. For those in the 1958-1970 birth cohort, who if born in Antofagasta would have experienced very high early life exposure, the SMRs were 38.3 (17.5-72.7) in 1989-2000 and 16.0 (10.1, 25.4) in 2001-2010. **Conclusions:** The relationship between arsenic in drinking water and subsequent bladder cancer mortality is quite extraordinary and without precedent in environmental epidemiology, including major impact among those who probably experienced early life exposure.

## **003.02.20. Residential Proximity to Agricultural Herbicides during Pregnancy and Childhood Leukemia in the Danish National Birth Cohort**

Deven Patel

*Deven Patel<sup>1</sup>, Steen Gyldenkærne<sup>2</sup>, Rena R. Jones<sup>1</sup>, Thomas Becker<sup>2</sup>, Sjurdur Olsen<sup>3</sup>, Chalotta Granström<sup>3</sup>, Leslie T. Stayner<sup>4</sup>, Mary H. Ward<sup>1</sup>*

**Abstract:** Background The majority (61%) of Denmark's land cover is agricultural. Cereals and grains are the major crops, and almost all acres of these crops are treated with herbicides. Based mostly on case-control studies, parental exposure to pesticides during pregnancy has been associated with increased risk of childhood cancer. Methods The Danish National Birth Cohort (DNBC) enrolled over 100,000 pregnant women 1996-2003. For childhood leukemias (diagnosed <15 years) through 2014 and 10% of the cohort (N=9,362, excluding non-singleton births and children with Down Syndrome), we linked addresses during the pregnancy to crop maps and crop-specific pesticide sales data to estimate the amount (g) of herbicides applied at distances within 100, 250, 500, 1000m of homes. We used Cox proportional hazard models to estimate hazard ratios (HR) and 95% confidence intervals (95%CI) for 18 herbicides with the highest use. Results There were 191 children diagnosed with childhood cancer, including 61 leukemia cases. Some herbicides were used on the same crops or applied as mixtures, resulting in high correlations (Spearman's rho: 0.46-1.00). For the highest tertile (vs. no pesticide use) within 500m from the home, we found increased risk of leukemia for MCPA+methabenzthiazuron (HR: 2.08, 95%CI: 1.06-4.07), dichlorprop-p/mecoprop-p (HR: 2.10, 95%CI: 1.07-4.11), benzonitrile herbicides (HR: 2.21, 95%CI: 1.14-4.29), thifensulfuron-methyl (HR: 2.09, 95%CI: 1.07,4.09), bentazone (HR: 2.20, 95%CI: 1.13-4.27), and phenmedipham (HR: 2.16, 95%CI: 1.10-4.23), without significant trends. Risk patterns at other distances from the home were similar but attenuated. There was no association with leukemia and use of glyphosate, clopyralid, 2,4-D, and 6 other herbicides. Conclusions This is the first prospective study to evaluate residential proximity to pesticide applications and childhood cancer, and provides additional evidence that pesticide exposures during pregnancy may increase childhood leukemia risk.

### **003.02.21. Brain Cancer Cluster Investigation Around a Factory Emitting Dichloromethane**

*2. Ministry of Labour, Welfare and Social Insurance, Nicosia, Cyprus, Nicosia, Cyprus.*

**Abstract:** Background: The health risks associated with dichloromethane (DCM) for the general population living near industrial activities have not yet been quantified, primarily due to lack of epidemiological datasets. In the absence of such human data, we undertook a cancer cluster investigation in Cyprus around a historically using DCM plant producing shoe soles that were globally exported. We designed the methodology to investigate the possible existence of a cancer cluster in the area around the factory (point zero) and within a radius of 500 meters. Methods: A retrospective comparative population study was designed using a group of cancer patients living or working in the chosen geographical area around the factory. Results: Mean stack emissions of DCM of 88mg/Nm<sup>3</sup> and flow rates of 850 g/h exceeded the permissible DCM limits established for industrial zones. Brain and central nervous system (CNS) cancer incidence rates showed significant ( $P < 0.001$ ) increase in the study area around the plant when compared with those observed in other areas of Cyprus. Calculated standardized incidence ratios for brain/CNS after adjusting for the age at diagnosis ranged from 11.3-25.7 [mean 6.5 (3.02 : 12.3)] for the study area. Conclusions: We showed the association between chronic, unintentional DCM exposures and brain/CNS cancer cases for the general population located in a residential area being in close proximity with a plant historically emitting DCM.

### **003.02.22. Geographic Location and Its Contribution to Disparities in Ovarian Cancer Survival**

Carolina Villanueva

*2. School of Medicine, University of California, Irvine, Irvine, CA, United States.*

*3. Department of Epidemiology, University of California, Irvine, Irvine, CA, United States.*

**Abstract:** Background: Over 14,000 American women die of ovarian cancer (OC) every year. Disparities in survival are observed by race and socioeconomic status (SES), even after adjusting for treatment received. Geographic location has been identified as an independent predictor of survival. This study aims to determine the impact of geographic location on advanced-stage OC survival in California (CA, USA), relative to race and SES. Methods: Women diagnosed with advanced-stage epithelial OC between 1996 and 2014 were identified through the CA Cancer Registry, with follow up obtained through 2016. Cox proportional hazard models with a smooth for residential location were used to identify geographic patterns in survival. We assessed the impact of distance traveled for care, distance to closest high-quality-of-care (QOC) hospital, race, and SES on survival, adjusting for treatment received, age, and cancer characteristics. Results: Among the 20,095 women diagnosed at late stages, survival time ranged from 0 to 20.2 years, with a median of 2.0 years. Median survival time was shortest for women of Black race (1.3 years) and the lowest SES (1.5 years). Patients who traveled the greatest distance to receive care (>32km) had better survival (hazard ratio [HR],0.85; 95% confidence interval [CI],0.80-0.90), whereas women living furthest (> 48km) from a high-QOC hospital had poorer survival (HR,1.06; 95% CI,1.00-1.14). Women of lower SES and minority race were less likely to travel far for care. Geographic location was a significant predictor of survival, even after controlling for cancer characteristics and treatment received, with Central Valley showing a significant hot spot of high HR that was attenuated after adjusting for race and SES. Conclusions: Geographic location is an independent predictor of OC mortality in CA. Traveling greater distances for care was associated with better survival. Minority women and those of lower SES are disproportionately affected by geographic barriers.

### 003.02.23. Spatiotemporal Patterns of Solar and UV Irradiances in the Contiguous United States

Ying Zhou

Ying Zhou<sup>1</sup>, Xia Meng<sup>2</sup>, Huanxin Zhang<sup>3</sup>, Caitlin Kennedy<sup>1</sup>, Jun Wang<sup>3</sup>, Yang Liu<sup>2</sup>

2. Rollins School of Public Health, Emory University, Atlanta, GA, United States.
3. Center for Global and Regional Environmental Research, University of Iowa, Iowa City, IA, United States.

**Abstract:** **BACKGROUND:** Skin cancer is the most common type of cancer in the United States. The majority of skin cancer is caused by overexposure to ultraviolet (UV) light. The National Environmental Public Health Tracking Program (EPHT) at CDC has collaborated with partners to develop and disseminate county-level daily UV irradiance (2005 to 2015) and total solar irradiance (1991 to 2012) data for contiguous United States. The objectives of this study are to present our methods for generating and evaluating UV and solar irradiance datasets, and to describe their spatial distribution and temporal trend. **METHODS:** UV dataset was derived based on measurements from Ozone Monitoring Instrument (OMI) aboard NASA's Aura spacecraft. For evaluation, erythemally weighted UV irradiance was compared with ground observations at 27 sites. Solar irradiance were extracted from National Solar Radiation Data Base (NSRDB) and SolarAnywhere data. In addition, we conducted regression analysis to understand long-term trends at both the national level and by state for UV and solar irradiances. **RESULTS:** When comparing UV irradiance from OMI with ground observations, the correlation coefficients range from 0.66 to 0.93 with an average of 0.86. Solar and UV irradiances both had a latitudinal gradient increasing towards the South, and a longitudinal gradient increasing towards the West. The lowest state averages occurred in Vermont for solar irradiance and Maine for UV irradiance. The highest state averages were both in Arizona. National annual average solar and UV irradiances both increased significantly over the years included in this analysis. We made both datasets available to the public through CDC's EPHT network. **CONCLUSIONS:** The UV dataset is currently the only publicly available, spatially resolved long-term UV radiation dataset covering the contiguous United States based on latest satellite remote sensing technique. These datasets allow for improved characterization of UV and sunlight exposure.

### 003.02.24. Towards Continuous Domain Models in Spatial Epidemiology

Garyfallos Konstantinoudis

*Garyfallos Konstantinoudis<sup>1</sup>, Haavard Rue<sup>2</sup>, Dominic Schuhmacher<sup>3</sup>, Ben Spycher<sup>1</sup>*

Abstract: One of the goals of spatial epidemiology is to identify areas with elevated disease risk. Such analyses are often hampered by the limited geographical resolution of the available data. When data are aggregated into spatial units, conditional autoregressive (CAR) models are commonly used. When data are available at higher resolution (e.g. geocodes), log-Gaussian Cox processes (LGCPs) provide a more natural modelling framework. In theory, LGCPs should perform better, but do they? We simulated data mimicking childhood leukaemia incidence in the Canton of Zurich in Switzerland (n=334 during 1985-2015). Geocoded locations of residence were available for the entire population. We randomly sampled case locations from these data under different risk scenarios. We considered 39 scenarios varying the shape of the true risk function (constant, step-wise, exponential decay), size of the high-risk areas (1, 5 and 10 km radii), risk increase in the high-risk areas (2 and 5-fold) and the number of cases (n, 5n and 10n). We compared the ability of the models to recover the true risk surface using the root mean integrated squared error (RMISE) and their ability to identify high-risk areas using area under the ROC curve (AUC). CAR models recovered the step-wise true risk surface with lower error across all scenarios (range of median RMISE across scenarios: 0.05-0.25) compared to LGCPs (median RMISE: 1.80-37.2). For exponential decay risk surfaces, however, LGCPs performed better (median RMISE: 1.70-20) compared to CAR (median RMISE: 1.80-32) in almost all scenarios. The ability to detect high-risk areas was higher for LGCPs (median AUC: 0.81-1) compared to the CAR model (median AUC: 0.65-0.93) across almost all scenarios. Our simulation study suggests that, under realistic scenarios, continuous domain models outperform discrete domain models in estimating risk surfaces and identifying high-risk areas. This argues for moving towards continuous domain models in spatial epidemiology.

## 003.02E. Health Effects Related to PCBs Exposure

### **003.02.25. Prenatal Exposure to Polychlorinated Biphenyls and Mercury Are Associated with Insulin-Like Growth Factor 1 and Thyroid-Stimulating Hormone in Cord Plasma**

Miyuki Iwai-Shimada

*2. Tohoku University Graduate School of Medicine, Sendai, Japan.*

**Abstract:** Impact on maternal endocrine system during pregnancy may also affect growth and development of a fetus. Certain toxic elements and polychlorinated biphenyls (PCBs) are known to disturb human endocrine system. In our previous study, we showed that birth weight were affected by prenatal PCBs and methylmercury exposure. In this study, we used the data from the Tohoku Study of Child Development in Japan. The objective of the study was to evaluate the effect of prenatal exposure to methylmercury, arsenic, cadmium, lead, and PCBs on insulin-like growth factor 1 (IGF-1) and thyroid related hormones (TSH, T3, freeT3, T4 and freeT4) in cord blood. Those factors are considered to be associated with fetal growth. Elements except for mercury were analyzed by an inductivity coupled plasma mass spectrometry. Mercury levels were measured using a cold vapor atomic absorption spectrometer. IGF-1 and insulin-like growth factor binding protein 1 (IGFBP1) were determined by an enzyme-linked immunosorbent assay (ELISA). Thyroid related hormones were assessed by an electrochemiluminescence immunoassay. The data were examined by Pearson's correlation and multiple regression analyses. The IGF-1 in cord plasma was negatively associated with PCB concentrations in cord blood, especially with tri-, tetra-, penta-, hexa- and hepta-chlorobiphenyls. Cord plasma free T4 was negatively associated with mercury concentrations in cord blood. This study indicated PCBs and mercury could affect birth weight through altering the IGF1 and T4 mechanism. Further studies are necessary to investigate the effect of decrease in IGF-1 and thyroid hormones on birth weight.

### 003.02.26. Intrauterine Exposure to Polychlorinated Biphenyls (PCBs) and Anogenital Distance in Israeli Newborns

Eva Siegel

*Eva Siegel<sup>1</sup>, Revital Sheinberg<sup>2</sup>, Rimona Keidar<sup>2</sup>, Elkana Kohn<sup>2</sup>, Amalia Levy<sup>3</sup>, Ronit Lubetsky<sup>4</sup>, Dror Mandel<sup>4</sup>, Pam Factor-Litvak<sup>1</sup>, Matitiahu Berkovitch<sup>2</sup>*

- 1. Epidemiology, Mailman School of Public Health Columbia University, New York, NY, United States.*
- 2. Assaf Harofeh, Zerifin, Israel.*
- 3. Ben Gurion University, Beersheva, Israel.*
- 4. Tel Aviv Medical Center, Tel Aviv, Israel.*

Abstract: Polychlorinated biphenyls (PCBs) are widespread environmental contaminants due to their extensive past use, long-range transport and persistence in adipose tissues of humans and animals. Specific congeners exhibit structural similarities to steroid hormones. This raises concerns regarding the effects of exposure on reproductive development in neonates. Here, we examine associations between prenatal exposure to PCB congeners 118, 138, 153 and 180 and anogenital distance in a cohort of newborns in Israel. We measured serum concentrations of the four PCB congeners in 173 pregnant women presenting to the delivery room at Assaf Harofeh Medical Center. Mothers completed questionnaires on lifestyle and demographic variables. Birthweight, length, head circumference and anogenital distances were measured using a standard protocol. Regression models estimated associations between maternal PCB exposure and infant anogenital measurements, birthweight, birth length and head circumference, controlling for confounding variables. Mean penile width, anoscrotal length, and anopenile length were 11.04 mm [standard deviation (sd): 1.14 mm], 23.43 mm (sd: 3.58), and 44.58 mm (sd: 4.58 mm) in male infants (n=90); mean anoforchetall and anoclitoral distances were 14.34 mm (sd: 2.17 mm) and 34.23 mm (2.74 mm) in female infants (n=83). Mean maternal serum concentrations were 2.91 ng/ml (sd: 1.93), 4.50 ng/ml (sd: 3.04), 7.42 ng/ml (sd: 5.41), and 4.98 ng/ml (sd: 3.62) for PCB-118, 138, 153 and 180, respectively. Higher maternal concentrations of all four PCBs were associated with reduced anogenital distance measures in male infants but not in female infants. No associations were found between PCB exposure and birthweight, length and head circumference. These results are significant as anogenital distance is associated with male reproductive problems later in life; thus, there are implications for later life reproductive health.

### **O03.02.27. Associations of in Utero Polybrominated Diphenyl Ethers (PBDEs) and Polychlorinated Biphenyls (PCBs) with the Mid-Childhood Gut Microbiome**

Hannah Laue

*Hannah E. Laue<sup>1</sup>, Wei Zhang<sup>2</sup>, Larissa Takser<sup>3</sup>, Andrea Baccarelli<sup>4</sup>*

- 4. Department of Environmental Health Sciences, Columbia Mailman School of Public Health, New York, NY, United States.*

**Abstract:** Background: The gut microbiome is influenced by early-life exposures, but-despite potentially enormous implications for child health-it is understudied in environmental health. This pilot study, the first to explore the effect of in utero exposures on long-term development of the microbiome, examined the association between first trimester and perinatal exposure to PBDEs and PCBs and the mid-childhood gut microbiome. Methods: We measured metabolites of PBDE-47, -99, -100, and -153 and PCB-138, -153, and -180 in maternal plasma during the first trimester (n=18) and at delivery (n=25) using gas chromatography coupled with tandem mass spectrometry in women from Sherbrooke, Quebec who identified as white and ever breastfed the child subject. The structure of the mid-childhood (6-8 years) fecal microbiome was measured using 16S rRNA sequencing. Sequences were processed using QIIME and paired to operational taxonomic units (OTUs) using SILVA v128. To test for differences at the OTU level, we used the MiCAM algorithm, adjusting for delivery mode and socioeconomic status. Results: Higher first trimester PCB-153, -180, and  $\Sigma$ 3PCB blood concentrations were associated with a higher relative abundance of Propionibacteriales and Propionibacteriaceae in mid-childhood. Higher PCB-180 and  $\Sigma$ 3PCB were associated with higher relative abundance of Bacillales Family XI. Higher PBDE-99 exposure was associated with a decrease in uncultured bacteria within the Ruminococcaceae NK4A214 group and PBDE-47 was associated with differences in Ruminococcus 2, but the direction of the association varied by lower-level taxa. These OTU-level changes did not result in differences to within- or between-subject diversity. Exposures at delivery were not associated with differences in OTUs. Conclusion: Early-life exposure to PCBs and PBDEs was associated with differences in the mid-childhood gut microbiome. Larger studies are needed to confirm these results and explore health implications.

**O03.02.28. Polychlorinated Biphenyls, Thyroid Hormones, and Neuropsychological Functioning over a 14-Year Period, among Healthy, Older Adults from New York State**

**Abstract:** Polychlorinated biphenyls (PCBs) are neurotoxic persistent organic pollutants linked to changes in thyroid hormones (THs) and cognitive function in older adults. However, no prior studies have evaluated the association over time. We assessed the effect of serum PCB levels on THs and neuropsychological tests (NPTs) over a 14-year period among men and women, ages 67 to 88 years, from New York State. We analyzed serum for PCBs using gas-chromatography-isotope dilution mass-spectrometry, enzymatically measured 5 THs and 2 TH-transport proteins, and administered a battery of 33 NPTs. Of the original 253 participants, the 116 that completed follow-up were significantly younger, more physically active, and had higher income and NPT scores. Baseline serum PCB levels were higher than the general US population, but significantly declined over time (-18%). We found that 75% higher baseline PCB levels were associated with 4.5% lower free triiodothyronine (fT3) (CI=-8.0%, -1.0% p-value=0.013), and 3.8% higher transthyretin (TTR) (CI=0%, 7.7% p-value=0.047) levels at follow-up, adjusted for age, sex, smoking, TH medication, and follow-up time. No other THs were impacted. PCBs were not significantly related to NPTs at follow-up, or change in NPT scores over time, after adjusting for age, sex, smoking, total lipids, and follow-up time. Adjustment for loss to follow-up using multiple imputation and inverse probability weighting had minimal impact on estimates, but we cannot rule out healthy survivor bias. Results suggest that among healthy older adults with low to moderate exposure, PCBs were related to subtle decreases in fT3 and increases in TTR over time, but not cognitive function. Future studies among older adults should conduct more frequent follow-up assessments to mitigate the potential impacts of selective survival, and evaluate health habits that may be neuroprotective.

### **O03.02.29. Environmental Exposures to PCDDs, PCDFs, and PCBs and Mechanism of Steatohepatitis in the Anniston Community Health Survey II**

Matt Cave

*3. NIEHS, Research Triangle Park, NC, United States.*

Abstract: PCDDs, PCDFs, and some PCBs activate the aryl hydrocarbon receptor (AhR); but non-dioxin like (NDL) PCBs do not. We previously reported a high prevalence of suspected nonalcoholic steatohepatitis (NASH) associated with PCB exposures in the Anniston Community Health Survey (ACHS). Here, we determine if dioxins and NDL PCB exposures were associated with serologic biomarkers of NASH in the subgroup of ACHS-II participants with suspected liver disease. The total dioxin toxic equivalency (TEQ) was determined by summing the TEQs for serum PCBs, PCDDs, and PCDFs using WHO toxic equivalency factors. Disease biomarkers were measured by ELISA or Milliplex. Subjects were categorized as having suspected liver disease if serum cytokeratin 18 was elevated. Linear regression models examined associations between TEQ or  $\Sigma$ NDL PCBs with NASH biomarkers in the suspected liver disease subgroup. In 345 adult participants, the prevalence of suspected liver disease was 62%. These subjects were at risk for NASH due to a high prevalence of overweight/obesity and diabetes. Suspected liver disease was significantly associated with male sex, non-Hispanic White race/ethnicity, increased liver enzymes, and a trend towards increased diabetes. Both TEQ and  $\Sigma$ NDL PCBs were associated with altered intermediary metabolism biomarkers (increased LDL, VLDL, phospholipids; and decreased HOMA-IR). TEQ was also associated with decreased HOMA-B. TEQ was associated with increased TNF $\alpha$ , IL-12 and CXCL11; while  $\Sigma$ NDL PCBs was associated with increased IL-13. Both TEQ and  $\Sigma$ NDL PCBs were positively associated with TGF $\beta$ . Neither exposure biomarker was positively associated with either CK18 or transaminases. In ACHS-II participants with suspected liver disease we found associations with altered biomarkers of liver intermediary metabolism, inflammation, fibrosis, and synthetic function; but not cell death. The potential role of the AhR, dioxins, and NDL PCBs in NASH progression warrants further investigation.

### **003.02.30. Organochlorine Pesticides and Polychlorinated Biphenyls (PCBs) in Early Adulthood and Blood Lipids over a 23-Year Follow-Up**

Jose Suarez-Lopez

*5. Department of Laboratory Medicine and Pathology, University of Minnesota, Minneapolis, MN, United States.*

**Abstract:** Background: Some evidence in humans suggests that persistent organic pollutants (POPs), including organochlorine pesticides (OCPs) and polychlorinated biphenyls (PCBs), may alter the blood lipid composition. We analyzed associations between blood POPs concentrations in young adulthood with blood lipid levels up to 23 years later. Methods: The study included 180 participants (50% diabetic and 50% without diabetes). Serum POPs were measured in year 2 of follow-up (participant ages 20-32y), and lipids in plasma at follow-up years 2, 7, 10, 15, 20 and 25. 32 POPs were detectable in  $\geq 75\%$  of participants (23 PCBs, 8 OCPs and PBB-153). We created summary scores for PCBs and OCPs for both wet-weight, and lipid standardized (LP) concentrations. We used repeated measures regression adjusting for demographic factors, BMI, smoking, diabetes status, among others. Results: We observed positive associations of the 23 LP-PCB score with total cholesterol ( $\beta$ per SD increase [95%CI]: 5.0 mg/dL [0.7, 9.2]), triglycerides (7.8 mg/dL [-0.9, 16.5]), LDL (4.2 mg/dL [0.2, 8.2]), oxidized LDL 3.4 U/L (-0.05, 6.8), and cholesterol/HDL ratio (0.2 [0.02, 0.3]). The associations for triglycerides (14.7 mg/dL [0.4, 20.1]), cholesterol/HDL (0.33 [0.09, 0.56]) and, to some extent, LDL (4.7 mg/dL [-1.6, 10.9]) were only observed among participants in the upper 50th percentile of BMI. PBB-153 had positive curvilinear associations with most outcomes. Conclusions: PCBs and PBB-153 measured in young adulthood were positively associated with prospective alterations in most blood lipid components, with evidence of effect modification by BMI. Further longitudinal studies with multiple measures of POPs overtime are needed.

## O03.02F. New Advancements in Consumer Exposure Risk Assessment

### **O03.02.31. High-Throughput Exposure Modeling for 8000 Tox21 Chemicals in the Environment and in Consumer Products Based on a Modified USEtox Model**

Olivier Jolliet

*Lei Huang<sup>1</sup>, Olivier Jolliet<sup>1</sup>, Peter Fantke<sup>2</sup>*

*1. Environmental Health Sciences, University of Michigan, Ann Arbor, MI, United States.*

*2. Management Engineering, Technical University of Denmark, Lyngby, Denmark.*

Abstract: Near-field human exposure to chemicals in consumer products has been gaining increased attention. However, exposure models used in life cycle impact assessment and risk assessment are usually limited to chemicals emitted to the far-field environment. We thus developed a framework based on the widely used USEtox model to integrate near-field chemical exposures, which converts transfer rate constants to direct transfer fractions from emission to receiving compartments, and connects near-field compartments (product, near-person air) with far-field compartments (e.g. air, water, soil) via wastewater treatment and landfill. By inversion of the direct transfer fraction matrix, cumulative transfer fractions from products to various human receptors are obtained, also known as product intake fractions (PiFs). The direct transfer fractions from different product and emission scenarios are calculated by 7 underlying models (skin surface, object surface, article interior, indoor air, food contact material, pesticide, direct environmental emission). Our framework was applied in batch mode to generate high-throughput estimates of PiFs for 8167 Tox21 chemicals via four pathways: near-field (residential), dietary, far-field industrial, and far-field pesticide. The total PiF summing users and non-users (i.e., general population) across all exposure routes for the 8167 chemicals ranges from 1.9E-4 to 0.34, from 4.8E-6 to 0.19, and from 6.3E-6 to 0.22 via residential, dietary and far-field industrial pathways, respectively. For the far-field pesticide pathway, the total PiF ranges from 1.9E-7 to 0.1 and from 2.9E-5 to 0.09 assuming herbicide and non-herbicide applications on tomatoes, respectively. In general, the residential pathway is associated with the highest total PiF, again highlighting the importance of near-field chemical exposures. Further efforts are needed to identify the chemicals that are actually associated with the various pathways to obtain more refined estimates.

### **003.02.32. Health Risk Assessment of Inhalation Exposure to Long-Chain Aliphatic Hydrocarbons and Aldehydes, TMB, MCH, and MIBK in Indoor Environments**

*3. Meiji University Faculty of Pharmacy, Nagoya, Aichi, Japan.*

**Abstract:** Background: In the past decades, indoor air pollution has become a major public health concern. Therefore, Japan has established indoor air quality guidelines for 13 chemicals, including formaldehyde and toluene. However, the types and concentrations of these pollutants have not been consistent over time due to alterations in lifestyle and development of novel household products and building materials. Our recent nationwide surveys in Japan revealed that C8-C16 aliphatic saturated hydrocarbons, C6-C9 aliphatic saturated aldehydes, trimethylbenzenes (TMBs), methylcyclohexane (MCH), and methyl isobutyl ketone (MIBK) have been frequently detected in high concentrations in indoor air samples taken from houses. However, the risk levels have not been assessed to date. Methods: We derived the reference concentrations (RfCs) for these pollutants and assessed their risk levels. RfC is an estimation of a continuous inhalation exposure concentration that is not likely to carry an appreciable risk of deleterious health effects. Results: RfCs derived for the different pollutants were as follows: for hydrocarbons, RfC of 246  $\mu\text{g}/\text{m}^3$  from no-observed adverse effect level (NOAEL) of 138  $\text{mg}/\text{m}^3$  (adrenal gland effects in rats) and uncertainty factor (UF) of 100; for aldehydes, RfC of 130  $\mu\text{g}/\text{m}^3$  from lowest-observed adverse effect (LOAEL) of 363  $\text{mg}/\text{m}^3$  (nasal effects in dogs) and UF of 500; for TMBs, RfC of 110  $\mu\text{g}/\text{m}^3$  from NOAEL of 123  $\text{mg}/\text{m}^3$  (neurobehavioral effects in rats) and UF of 200; for MCH, RfC of 2857  $\mu\text{g}/\text{m}^3$  from NOAEL of 1600  $\text{mg}/\text{m}^3$  (renal effects in rats) and UF of 100; and for the MIBK, RfC of 329  $\mu\text{g}/\text{m}^3$  from LOAEL of 1845  $\text{mg}/\text{m}^3$  (renal effects in rats) and uncertainty factor (UF) of 1000. In our surveys, the maximum concentrations of hydrocarbons, aldehydes, TMBs, MCH, and MIBK were 1456  $\mu\text{g}/\text{m}^3$ , 250  $\mu\text{g}/\text{m}^3$ , 368  $\mu\text{g}/\text{m}^3$ , 481  $\mu\text{g}/\text{m}^3$ , and 151  $\mu\text{g}/\text{m}^3$ , respectively. Conclusion: Our results suggest that the risk levels for hydrocarbons, the aldehydes, and TMBs indicate a "potential for health risk".

### **O03.02.33. Prediction of Composition and Emission Characteristics of Articles in Support of Exposure Assessment**

Cody Addington

*Cody Addington<sup>2</sup>, Katherine Phillips<sup>1</sup>, Kristin Isaacs<sup>1</sup>*

*1. US EPA, Research Triangle Park, NC, United States.*

*2. Oak Ridge Institute for Science and Education, Research Triangle Park, NC, United States.*

Abstract: The risk to humans from chemicals in consumer products is dependent on both hazard and exposure. The prediction and quantification of chemical exposure from household articles such as furniture and building materials is an ongoing effort. As opposed to, for example, cosmetic formulations which are regulated by the FDA, the chemical composition of articles are less clear, as are the resulting chemical emission characteristics and exposures. We have developed a modeling methodology to predict the weight fraction of chemicals in a polymeric substrate and corresponding emission characteristics based on chemical and substrate structure. We constructed a database of reported and measured chemical concentrations in articles from publicly available sources including Health Product Declarations (HPDs). This database was then used to train a random forest algorithm which predicts a chemical weight fraction bin based on chemical structure and properties. From the predicted weight fractions and chemical properties, we applied a group contribution method, UNiversal quasi-chemical Functional-group Activity Coefficients-Free Volume (UNIFAC-FV), to approximate steady-state gas phase concentrations ( $y_0$ ) at the substrate surface. The model was compared to published experimental  $y_0$  data from chamber experiments. The resulting estimates of  $y_0$  can be used to parameterize existing high-throughput exposure models for substrate-chemical combinations found in consumer articles. Thus, from only the "first-principles" of chemical and substrate molecular structure, we can generate an estimate of chemical exposure for use in screening-level risk evaluation. This abstract does not reflect EPA policy.

### **O03.02.34. Determination of Chemical Constituents of Recycled Consumer Products**

Charles Lowe

*Charles Lowe<sup>2</sup>, Katherine Phillips<sup>1</sup>, John Wambaugh<sup>1</sup>, Alice Yau<sup>3</sup>, Kristin Favela<sup>3</sup>, Kristin Isaacs<sup>1</sup>*

- 2. Oak Ridge Institute for Science and Education, Research Triangle Park, NC, United States.*
- 3. Southwest Research Institute, San Antonio, TX, United States.*

Abstract: Recycled materials are commonly found in various modern consumer products. Although these products are generally regarded as being comparable to those made from non-recycled (virgin) materials, differences in chemical formulation may be unknown to the consumer or even manufacturer. A suspect screening analysis was applied to 215 products (159 recycled and 56 virgin) across 7 categories (including plastic children's toys, housing construction materials, and paper products) to rapidly characterize chemical content. Two-dimensional gas chromatography time-of-flight mass spectrometry (GCxGC-TOFMS) was performed on samples extracted with a standardized methodology. Tentatively identified and confirmed chemicals and estimated concentrations were determined by comparing sample spectra to the National Institute of Standards and Technology v.2.2.07-2014 spectral library. A total of 1,042 chemicals were tentatively identified in recycled materials and 677 in virgin materials. Recycled materials contained larger numbers of flame retardants, fragrances, and colorants. A random forest model was constructed which used the presence/absence of the tentatively identified compounds to classify products as made of recycled or virgin materials. The model was validated using 5-fold cross validation and Y-randomization and achieved a balanced accuracy of 76%. Hierarchical clustering analysis was performed to identify groups of chemicals potentially associated with unique exposure sources (e.g., recycling processes). While presence in a product is only a prerequisite to exposure, the occurrence of chemicals that are unexpected or common across multiple products can guide research priorities. The chemicals and associated concentrations identified in this study can be used in future studies to parameterize existing exposure models or identify novel exposure pathways which are currently neglected in product exposure assessments. This abstract does not necessarily reflect US EPA policy.

### **O03.02.35. A Review of Global Legal Regulations on the Permissible Levels of Heavy Metals in Cosmetics with Special Emphasis on Skin Lightening Products**

Bian Liu

*Irmina M. Michalek<sup>1</sup>, Emma K. Benn<sup>2</sup>, Chi Wen<sup>3</sup>, Richa Deshpande<sup>4</sup>, Bian Liu<sup>4</sup>*

- 1. Faculty of Social Sciences, University of Tampere, Tampere, Finland.*

- 3. Master of Public Health Program, Icahn School of Medicine at Mount Sinai, New York, NY, United States.*
- 4. Department of Population Health Science and Policy, Icahn School of Medicine at Mount Sinai, New York, NY, United States.*

**Abstract:** Introduction the use of skin lightening products to inhibit melanogenesis is common among non-White populations. The practice has historically been associated with complexion- and/or race-related oppression and classism, but more recently has been perceived as an ungendered fashion trend. Chronic exposure to heavy metals found in many bleaching cosmetics may have serious health consequences, perhaps prompting the need for stricter regulations. Aims of the study Our study aimed to assess the current global legal regulations regarding the permissible content of four heavy metals (mercury, lead, arsenic, and cadmium) in cosmetic products and to explore whether the composition of skin bleaching products has adhered these regulations. Materials and methods We comprehensively reviewed publicly-available regulations on cosmetic products, extensively searching websites of relevant international organizations or government bodies. No language, regional, or temporal restrictions were applied. Results Fifty-five countries had regulations on the permissible content of heavy metals in skin lightening products. Approximately 46 countries had regulations for all four heavy metals, with varied maximum permissible levels and effective year of regulation. In both developed and developing countries, cosmetics with heavy metal content above the permitted limits were reported. Conclusions Legal regulations on heavy metals in skin lightening cosmetics exist in many high- and middle-income countries, while lacking in low-income countries. There is a need for enforcement of existing rules, and rigorous assessment of the effectiveness of these regulations. Moreover, there is a need for the global harmonization of the above standards, given increasing availability of skin lightening products including online sales. Meanwhile, education of consumers and cross-national sharing of information on cosmetics are needed to reduce the scope of the possible adverse effects of using skin lightening products.

### **O03.02.36. Estimation of Exposure to Preservatives from Modelling Clays and Slimes Use in Korea**

Ji Young Park

*Ji Young Park<sup>1</sup>, Miyoung Lim<sup>1</sup>, Kiyoun Lee<sup>1</sup>*

*1. Seoul National University, Seoul, Korea (the Republic of).*

Abstract: Modelling clays or slime have been used for art activities or playing thus popular to children. They may include preservatives to avoid the bacterial growth. Some preservatives can pose harmful effects. The purpose of this study was to investigate the contents of preservatives and to estimate dermal exposures of preservatives in modelling clays and slimes use by children. Sixty five modelling clays and fifteen slimes were selected and were analysed for preservatives. The nationwide survey was performed to get use patterns of modelling clays and slimes by home visit survey of 10,000 children divided into three age groups: 0~2, 3~6, and 7~12 years old. Based on chemical analysis results and exposure factors from nationwide survey, dermal exposure estimates were calculated using deterministic method and were determined by each age group. Five preservatives were detected: triclosan (range:7-261 µg/kg in clays, 132-153 µg/kg in slimes, detection rate 24/80), methyl paraben (7.1-3220 in clays, not detected in slimes, 6/80), methylisothiazolinone(MIT, 1.6-12 in clays, 1-5.7 in slimes, 22/80), chloromethylisothiazolinone(CMIT, 4-96 in clays, 2.2-43 in slimes, 21/80), octylisothiazolinone(OIT, 10-130 in clays, 85-93 in slimes, 23/80). Proportions of clays and slimes user population were 69.2% and 45.8%, and mean use frequencies were 5.4 and 9.8 per month, respectively. Mean times spent to play with products each use were 23 min (range: 5~200) and 17 min (range: 5~100). Exposure estimates of modelling clays were higher than those of slimes. For modelling clays, exposure estimate was the highest in 3-6 years old age group and for slimes, 7-12 years old group was the highest. Exposure levels were estimated based on the use pattern information representing children in Korea. Harmful preservatives were found in modelling clays and slimes. Depending on exposure pattern, these products use could cause unacceptable risk in worst cases.

## O03.02G. The Influence of Chemical Exposures on Vulnerable Populations

### O03.02.37. Iron Status and Its Associations with Blood and Plasma Divalent Metals among Children Aged 3 to 19 Years Old from Four First Nation Communities in Quebec

Emad Tahir

*Emad Tahir<sup>1</sup>, Pierre Ayotte<sup>1</sup>, Matthew Little<sup>1</sup>, Richard E. Bélanger<sup>1</sup>, Michel Lucas<sup>1</sup>, Donna Mergler<sup>3</sup>, Elhadji Laouan Sidi<sup>2</sup>, Nancy Gros-Louis Mc Hugh<sup>4</sup>, Melanie Lemire<sup>1</sup>*

*1. Axe santé des populations et pratiques optimales en santé, Centre de recherche du CHU de Québec-Université Laval, Quebec, QC, Canada.*

*2. Département de médecine sociale et préventive, , Université Laval, Quebec , QC, Canada.*

*3. CINBIOSE, Université du Québec à Montreal, Montreal, QC, Canada.*

*4. CSSS, Quebec, QC, Canada.*

**Abstract:** **OBJECTIVES:** In First Nations communities, iron deficiency (ID) is a frequent pediatric condition with diverse adverse outcomes. Iron is a divalent metal that share absorptive pathways with cadmium (Ca), cobalt (Co), manganese (Mn), lead (Pb) and zinc (Zn) in the gastrointestinal tract; ID upregulates their uptake and the likelihood of toxic levels in humans. The present study examines associations between ID status, its determinants, and other divalent metals among indigenous youth. **METHODS:** The 2015 First Nation Youth Environment and Health (JES! -YEH!) pilot study was conducted among children (3 to 19 y, n = 198) from four First Nations communities in Quebec. Blood and urine samples and anthropometric measurements were collected. Serum ferritin (SF), blood Cd, Pb, Mn, Co, plasma Zn urinary cotinine and hs-CRP levels were measured. Determinants (including traditional and market food consumption) were assessed using an interview-administered questionnaire, based on which nutritional intakes were calculated. Descriptive analyses and Structural Equation Models were used to test associations. **RESULTS:** There was a high prevalence of ID (21.8%). Fruit and juice consumption - via vitamin C intake - were the only food variables positively associated to SF (coefficient [95% CI]: 0.22 [0.11, 0.45]; 0.54 [0.28, 0.80]). Blood Mn was significantly higher than in the Canadian Health Measures Survey. SF was in turn inversely associated to blood Co and Mn (-0.26 [-0.34, -0.19]; -0.15 [-0.20, -0.11]). As a whole, fruits and juice consumption were inversely associated with blood Mn (-0.02 [-0.03, -0.01], -0.04 [-0.08, -0.01]) and Co (-0.03 [-0.06, -0.01], -0.07 [-0.14, -0.02]), via their positive association to vitamin C intake and SF. **CONCLUSIONS:** Our findings suggest that dietary interventions fostering higher consumption of foods naturally rich in vitamin C, which is known to enhance iron absorption, could decrease ID and ultimately, restore blood Mn and Co homeostasis.

### **003.02.38. Determinants of Selenoneine Concentration in Red Blood Cells of Inuit from Nunavik (Northern Québec, Canada) and Implications for Selenium Risk Assessment**

Matthew Little

*Matthew Little<sup>1</sup>, Melanie Lemire<sup>1</sup>, Adel Achouba<sup>2</sup>, Pierre Dumas<sup>2</sup>, Nathalie Ouellet<sup>3</sup>, Pierre Ayotte<sup>1</sup>*

*1. Social and Preventive Medicine, Université Laval, Quebec, QC, Canada.*

*2. Centre de Toxicologie du Québec, Institut national de santé publique du Québec, Québec, QC, Canada.*

*3. Centre de recherche du CHU de Quebec, Québec, QC, Canada.*

Abstract: Selenium (Se) is a trace element essential to human health, and is abundant in marine foods consumed by Inuit populations in Nunavik (northern Quebec, Canada), leading to exceptionally high whole blood Se levels. While most epidemiological studies examine plasma or whole blood Se, there is a dearth of research on specific Se biomarkers (e.g. selenoproteins and small Se molecules) and their health impacts. Selenoneine, a novel Se compound, is found in high concentrations in marine foods (and particularly beluga mattooq) and the red blood cells (RBCs) of populations that depend on them. We determined RBC selenoneine concentrations in Inuit adults (n=885) who participated in the Qanuippitaa? 2004 survey. Simple associations between RBC selenoneine and other Se and mercury (Hg) biomarkers were assessed, followed by a multiple linear regression analysis to determine factors (sociodemographic, lifestyle, and dietary) associated with RBC selenoneine concentrations. Selenoneine was abundant in the RBCs of this population; age and sex-adjusted geometric mean RBC selenoneine concentration was 118 µg/L (range: 1-3226 µg/L) and was much higher (p=0.001) among women (250 µg/L) than men (88 µg/L) across all regions of Nunavik after controlling for confounders. Increasing age (standardized β=0.24), higher body-mass index (β=0.07), female sex (β=0.10), living in a Hudson Strait community (compared to Hudson Bay and Ungava Bay; β=0.42), and beluga mattooq consumption (g/day; β=0.15) were positively associated with RBC selenoneine, while consumption of market meats (g/day; β=-0.08) was negatively associated with RBC selenoneine. RBC selenoneine is therefore an important biomarker of Se dietary intake from local marine foods in Inuit populations. These results underscore the need to re-evaluate risk assessments of Se intake and develop public health recommendations that reflect the complexities of Se speciation, particularly for Inuit and other populations that rely on marine foods.

### **003.02.39. Diffusion Imaging of the Corpus Callosum in Inuit Adolescents Chronically Exposed to Methylmercury**

Vincent Migneron-Foisy

*Vincent Migneron-Foisy<sup>1</sup>, Gina Muckle<sup>2</sup>, Sandra W. Jacobson<sup>3</sup>, Joseph L. Jacobson<sup>3</sup>, Pierre Ayotte<sup>4</sup>, Dave Saint-Amour<sup>1</sup>*

*1. Psychology, Université du Québec à Montreal, Montreal, QC, Canada.*

*2. Psychologie, Université Laval, Québec, QC, Canada.*

*3. Psychiatry and Behavioral Neurosciences, Wayne State University, Detroit, MI, United States.*

*4. Social and preventive medicine, Université Laval, Québec, QC, Canada.*

**Abstract:** Background: In comparison to the general population, the Inuit community of Northern Quebec (Nunavik) is highly exposed to environmental contaminants, in particular methylmercury. Impairments of cognitive and sensory functions in association with prenatal mercury (Hg) exposure have been previously reported in a longitudinal mother-child cohort study, the Nunavik Child Development Study (NCDS), but the brain substrates of these deficits remain to be elucidated. Methods: This study aimed at determining whether microstructural integrity of the corpus callosum, a structure implied in several brain functions, is altered by Hg exposure in 75 NCDS adolescent/young-adult participants (Mean age=18.4y; Range=16.2 to 21.9y) using diffusion Magnetic Resonance Imaging (MRI). The general fractional anisotropy (GFA) metric was extracted for 7 sections of the corpus callosum. The association between GFA and Hg blood levels at birth and at the time of MRI assessment was determined using multiple linear regressions after controlling for sex, age, alcohol/drugs dependence and co-exposure to selenium. Results: Results show that cord Hg was associated with a decrease of GFA in the rostrum ( $\beta = -.33$ ,  $p = .02$ ), i.e., the anterior part of the corpus callosum that connect the frontal lobes. This result remained significant after controlling for Hg level at time of assessment ( $\beta = -.35$ ,  $p = .03$ ). Hg level at time of assessment was associated with splenium GFA ( $\beta = .30$ ,  $p = .03$ ), the posterior section of the corpus callosum that connect the occipital cortices. However, this association was no longer significant after controlling for cord Hg ( $\beta = .26$ ,  $p = .11$ ). Conclusions: Exposure to Hg, especially exposure during fetal development, is associated with microstructural alterations of the corpus callosum in NCDS adolescents. These results are in agreement with previous findings reporting that prenatal exposure to Hg was associated with a decreased IQ and alterations in visual processing.

### **003.02.40. Risk Factors for Developing Anxiety in Inuit Adolescents from Nunavik**

Vickie Lamoureux

*Vickie Lamoureux<sup>2</sup>, Gina Muckle<sup>1</sup>, Françoise Maheu<sup>2</sup>, Joseph L. Jacobson<sup>3</sup>, Sandra W. Jacobson<sup>3</sup>, Pierre Ayotte<sup>1</sup>, Richard E. Bélanger<sup>1</sup>, Dave Saint-Amour<sup>4</sup>*

- 3. Wayne State University, Detroit, MI, United States.*
- 4. Université du Québec à Montreal, Montreal, QC, Canada.*

**Abstract:** Background: Anxiety among Inuit adolescents in the Arctic has not previously been studied empirically, although the evidence of major anxiety-related problems in this community. In addition to describe anxiety markers, we examined their relationships with diverse developmental risk factors including exposure to environmental chemicals, a specific subject of concerns in Nunavik. Methods: Anxiety was assessed in 89 Inuit participants (Mean age=18.4y; Range=16.2 to 21.9y) enrolled in the longitudinal Nunavik Child Development Study. They completed the Screen for Child Anxiety Related Emotional Disorders (SCARED) and the State-Trait Anxiety Inventory (STAI) assessing situational (State) and general (Trait) anxiety levels. Potential risk factors of anxiety documented through follow-ups were examined at birth, at 11 years of age and at the time of assessment, including blood levels of chemicals (Hg, lead, PCBs), nutrients and vitamins, as well as age, sex, IQ, drug/alcohol, bullying, family violence, food insecurity, crowding and SES. Results: Anxiety scores on both questionnaires were high, particularly for the SCARED, which mean score was above the clinical threshold. Multiple regression results show that significant risk predictors of the SCARED scores were exposure to Hg during childhood ( $\beta=.25$ ,  $p=.02$ ) and adolescence ( $\beta=.27$ ,  $p=.004$ ), food insecurity ( $\beta=.27$ ,  $p=.004$ ), bullying history ( $\beta=.21$ ,  $p=.03$ ) and female status ( $\beta=.26$ ,  $p=.01$ ). For the STAI, the only significant predictor was IQ ( $\beta= -.27$ ,  $p=.02$ ) on Trait, whereas concentration of cord blood Hg ( $\beta=.25$ ,  $p=.03$ ), home crowding during childhood ( $\beta=.34$ ,  $p=.002$ ), adolescence ( $\beta=.23$ ,  $p=.02$ ), food insecurity ( $\beta=.22$ ,  $p=.03$ ), vitamin E ( $\beta=-.25$ ,  $p=.02$ ) and selenium ( $\beta=.21$ ,  $p=.04$ ) were found to be the significant predictors of anxiety on State. Conclusions: Our findings show that Inuit adolescents are at risk for anxiety via multiple contributing factors, particularly chronic exposure to Hg, food insecurity and female status.

Abstract: Background/Aim. Perfluorononanoic acid (PFNA) and other perfluorinated compounds have various industrial uses, and possible sources of exposure include food packaging, consumer products, house dust and/or drinking water. Exposure to PFNA in children has been associated with alteration in thyroid hormones, which have critical roles in metabolism regulation and during brain development. In 2015, the pilot project Jeunes, Environnement et Santé / Youth, Environment and Health (JES!-YEH!) was conducted among children and youth (3-19y) in collaboration with four First Nation communities in Quebec (n=198). The present study aims at evaluating the associations between various perfluorinated compounds exposure and thyroid hormones levels, while adjusting for relevant co-variables. Methods and results. During this study, perfluorinated compounds, thyroid hormones (e.g TSH and free T4) iodine and creatinine were measured in blood and urine samples. Main findings showed low exposure to major perfluorinated compounds, excepted for PFNA (GM: 2.09 µg/L). Compared to the Canadian Health Measure Survey (GM: 0.71 µg/L), PFNA levels were significantly higher among Anishinabe participants (GM: 5.12 µg/L), and particularly among those aged 6 to 11 years old (GM: 9.44 µg/L). Despite multiples efforts with community partners, no local source was identified. Few participants had abnormal TSH and free T4 levels. Conversely, preliminary analyses show positive associations between PFNA and free T4 levels (Spearman's  $r=0.23$ ;  $p=0.0016$ ). When adjusted for age, age-squared, BMI-z-score, urinary creatinine and nation, free T4 levels remain positively associated with PFNA levels (Adjusted  $\beta=0.39$ ;  $p=0.0014$ ;  $R^2 = 0.24$ ). Conclusion. Overall, this pilot project suggest potential effects of PFNA as an endocrine disruptor, and highlight the importance of better investigating the sources and effects of disproportionate exposure to emerging environmental contaminants in indigenous communities.

### **O03.02.42. Getting It Right for Aboriginal People Gets It Right for Everybody: Reflections from Australia**

Melissa Haswell

*Melissa Haswell<sup>1</sup>, Lisa Jackson Pulver AM<sup>2</sup>*

*1. School of Public Health and Social Work, Queensland University of Technology, Kelvin Grove, QLD, Australia.*

Abstract: In 1997, the Australian National Health and Medical Research Council (NHMRC) realised that despite substantial epidemiological research on Aboriginal health, health disparities were not reducing. 'Research' was viewed as something done 'on' not 'with' Aboriginal people; some felt they were 'the most researched people on Earth'. Extensive Aboriginal-led consultation processes culminated in three 'NHMRC Road Maps' that inform ethical guidelines and funding, driving substantial change in the people, process and impacts of Aboriginal health research. Among the Road Map consultation's central tenets is the ultimate aim of Aboriginal health research to enhance Spirit and Integrity. This requires research processes to be empowering by operationalising (walking the talk) five core values (ways of working): Equality, Respect, Responsibility, Reciprocity, and Survival and Protection. This session focuses largely on causes and consequences of health disparities among Canadian Indigenous Peoples, whose colonial histories and environmental justice challenges parallel those of Indigenous Australians. Both groups also experience distress from disruption of intimate links between traditional foods and cultural identity exacerbated by pollution and climate change. This discussion on ethics reflects on some key questions about transcultural research with Indigenous Peoples; e.g. Are we doing enough to promote the development of Indigenous researchers to lead Indigenous research with their own voices? Does cross-cultural environmental epidemiology require mixed methods for validity and effective knowledge translation? To what extent are we operationalising empowering values in the research we undertake as partners with these communities? What does that look like in practice? Are we measuring it? Should we be heeding the NHMRC Road Maps about research values and ethics for everyone we work with; not only Indigenous Peoples, but all who enable and participate in our research?

## 003.02H. Water Contaminants and their Effects

### **003.02.43. A Simple Probabilistic Modelling Tool to Estimate Children's Blood Lead Levels Resulting from High Variations of Daily Exposure through Drinking Water in Schools and Daycares**

Mathieu Valcke

*Mathieu Valcke<sup>1</sup>, Marie-Hélène Bourgault<sup>1</sup>*

*1. Santé environnementale et toxicologie, Institut national de santé publique du Québec, Montreal, QC, Canada.*

**Abstract:** BACKGROUND Spatiotemporal variations of lead (Pb) concentrations in drinking water ([Pb]DW) from schools and daycares can exceed an order of magnitude, with rare transient peaks possibly surpassing 1 mg/L. Available kinetic models that predict blood Pb levels (BLL) in exposed children hardly allow to account for variations of such magnitude and frequency. Therefore the aim of this study was to develop a simple tool that simulates the daily evolution of BLL in children exposed to ([Pb]DW) at school or daycare. METHODS Basic toxicokinetic equations were assembled to simulate BLL in a typical infant, toddler and child, respectively aged 0.5, 2 and 6 years. Modelling tool validation was done by comparing its predictions of BLL at steady-state with those obtained with the widely accepted Integrated Exposure Uptake Biokinetic Model for Lead in Children (IEUBK). BLL were simulated for each typical individual assuming daily exposure to [Pb]DW over an academic year. Monte Carlo simulations were run to account for uncertainty and variability in [Pb]DW and model parameters. RESULTS The modelling tool predict steady-state BLL that fits ( $r^2 = 0.99$ ) IEUBK predictions for [Pb]DW in the range of 10 - 925  $\mu\text{g/L}$ . For a median [Pb]DW of 14  $\mu\text{g/L}$  (90th percentile = 168  $\mu\text{g/L}$ ), average annual BLL (median, 97.5th percentile) vary between 2.5 and 5.4  $\mu\text{g/dL}$  in infant and 1.9 and 3.9  $\mu\text{g/dL}$  in child. Correspondingly, maximum annual BLL are 3.4 and 7.8  $\mu\text{g/dL}$ , and 2.7 and 5.7  $\mu\text{g/dL}$ . The infant and child present BLL > 5  $\mu\text{g/dL}$  for up to respectively 191 and 24 days. Toddler's and infant's results are similar. CONCLUSIONS Exposure to [Pb]DW in schools and daycares may lead to increased BLL in children. Along with average level, the spatiotemporal nature of the exposure pattern is in itself an important determinant of BLL. Thus, better characterization, in schools and daycares, of [Pb]DW and children's drinking water consumption habits are required to evaluate their resulting risk of increased BLL.

### **003.02.44. Environmental Justice and Drinking Water Quality in U.S. Public Water Supplies**

Laurel Schaidler

*Laurel A. Schaidler<sup>1</sup>, Lucien Swetschinski<sup>1</sup>, Ruthann Rudel<sup>1</sup>*

*1. Silent Spring Institute, Newton, MA, United States.*

**Abstract:** Low-income and minority communities often face disproportionate burdens of exposure to pollution, and associations with race and ethnicity persist even after accounting for income. However, few studies have investigated links between drinking water quality and environmental justice. The goal of our study was to evaluate associations between drinking water quality and characteristics of public water supplies and demographics of the communities they serve. We compiled county-level demographic data from the U.S. Census Bureau and water system characteristics from U.S. EPA's Safe Drinking Water Information System. We obtained data for regulated contaminants (lead, TCE, trihalomethanes) in around 40,000 community water systems (CWSs) from individual state drinking water programs. Data for 17 unregulated contaminants were gathered from EPA's Unregulated Contaminant Monitoring Rule (UCMR) program (2013-2015), which included 4,650 CWSs serving 240 million people (every large supply serving >10,000 customers and a subset of small supplies). We found that percent of Hispanic residents and percent of residents living in urban areas were associated with increased likelihood of detection, or exceedance of health guidelines, for a variety of unregulated industrial (e.g., 1,4-dioxane, PFASs) and inorganic (e.g., chromium) contaminants and disinfection byproducts (e.g., chlorate). Percent Hispanic and percent urban residents were also associated with increased likelihood of at least one exceedance of a health guideline for the UCMR contaminants in our analysis. We further observed positive associations between wealth-related factors (lower rates of poverty, higher rates of homeownership) and industrial, inorganic, and disinfection-related UCMR contaminants. The relationships we identified between demographics and levels of unregulated contaminants are similar to those that we previously observed for nitrate; future work will extend these analyses to lead, TCE, and trihalomethanes.

### **O03.02.45. Estimating Exposure to 1,3-D in Drinking Water Using Groundwater Monitoring Data and PRZM-GW Modeling**

Ian van Wesenbeeck

*1. Corteva Agrisciences, Salem, OR, United States.*

*2. risksciences.net, Long Boat Key, FL, United States.*

Abstract: 1,3-dichloropropene is a soil fumigant used for the control of nematodes in high valued fruit, nut and vegetable crops globally, and is applied at rates ranging from 50 to 350 kg/ha depending on the nematode pressure and crop type. Significant monitoring efforts have been undertaken over the past four decades by public and private institutions, given the widespread agricultural use and the environmental fate and metabolism data that suggest the potential for 1,3-dichloropropene (1,3-D) to leach to groundwater. The database of monitoring studies includes a survey conducted by various state agencies across the United States between 1980 and 1990, and analysis of ground water samples collected by US state and federal government agencies including the US EPA and the United States Geological Survey (USGS) since 1991. Also, tap water monitoring studies have been conducted in five major 1,3-D use regions in the United States, and in high-use regions in the EU and Canada. In total these studies report 1,3-D ground water monitoring results from hundreds of sites and thousands of water samples. The extensive ground water monitoring information developed through decades of monitoring supports the conclusion that soil fumigation with 1,3-D poses negligible risk from drinking water exposure. The lack of significant detections of 1,3-D from targeted monitoring studies is because of its high volatility and rapid degradation in most agricultural soils as well as the rapid degradation of 1,3-D and its metabolites in aerobic aquatic systems, and the rapid hydrolysis of 1,3-D in water. The water monitoring results are corroborated by PRZM-GW modeling when recently generated 1,3-D degradation half-lives in aerobic soil and water are used to parameterize the model. The results of both the modeling and monitoring can be used to assess human exposure and risk to 1,3-D via drinking water.

### **O03.02.46. Individual and Additive Disinfectant Byproducts in Community Drinking Water Systems and Associations with Colorectal and Bladder Cancer Incidence, Accounting for Population Served**

Alison Krajewski

*Alison K. Krajewski<sup>1</sup>, Monica P. Jimenez<sup>2</sup>, Danelle Lobdell<sup>3</sup>, Timothy Wade<sup>3</sup>, Jyotsna Jagai<sup>4</sup>*

*3. National Health and Environmental Effects Research Laboratory, US EPA, Chapel Hill, NC, United States.*

*4. Environmental and Occupational Health Sciences, University of Illinois at Chicago, Chicago, IL, United States.*

Abstract: Disinfectant byproducts (DBPs) haloacetic acids (HAA5) and total trihalomethanes (TTHM) used in community water systems (CWS) are potential bladder and colorectal carcinogens. Studies neglect to account for how exposures may differ within counties based on population served (PS) by CWS, which provides estimates of individual exposure. CWS concentration data for HAA5 and TTHM with PS were obtained for eight US states. These were summed to create additive DBP exposure and aggregated to the county-level to construct three cumulative county-level HAA5, TTHM, and additive DBP exposure metrics: unadjusted for PS; controlled for PS (as a covariate); and accounted for PS (concentration multiplied by proportion of PS by county population). Poisson regressions estimated incidence rate ratios (IRR) and 95% confidence intervals for associations between colorectal and bladder cancer and DBP, HAA5, and TTHM exposure tertiles, adjusting for potential confounders. For unadjusted DBP tertiles (<331 parts per billion (ppb), 331-732 ppb, >732ppb), the IRRs for colorectal cancer were 1.27 (1.22,1.32) and 1.58 (1.53,1.64) for tertiles 2-3, compared to <331 ppb, the lowest exposure category. For DBP tertiles controlled by PS, the IRRs were 1.27 (1.22,1.32) and 1.59 (1.54,1.65) for tertiles 2-3, compared to <331 ppb. After accounting for PS (<178 ppb, 178-502 ppb, >502 ppb), the IRRs were 0.92 (0.88,0.96) and 1.46 (1.41,1.51) for tertiles 2-3, compared to <178 ppb. Associations between colorectal cancer and HAA5 and TTHM tertiles were similar to the DBP tertiles. Associations between bladder cancer and HAA5, TTHM, and DBP tertiles were also similar to colorectal. Differing measures of PS by CWS in measured drinking water HAA5, TTHM, and DBP concentrations resulted in positive but varied associations to colorectal and bladder cancer. Thus, PS may need to be considered when developing drinking water exposure measures. This abstract does not reflect EPA policy.

### **003.02.47. Bladder Cancer Burden from Exposure to Trihalomethanes in Drinking Water in the European Union**

David Rojas-Rueda

*Manolis Kogevinas<sup>1</sup>, Iro Evlampidou<sup>1</sup>, David Rojas-Rueda<sup>1</sup>, Laia Font-Ribera<sup>3</sup>, Nathalie Costet<sup>6</sup>, Neil Pearce<sup>4</sup>, Paolo Vineis<sup>5</sup>, Cristina Villanueva<sup>2</sup>*

1. ISGlobal, Barcelona, Spain.
2. ISGlobal, Barcelona, Spain.
3. ASPB, Barcelona, Spain.
4. LSHTM, London, United Kingdom.
5. ICL, London, United Kingdom.
6. INSERM, Rennes, France.

**Abstract:** **BACKGROUND and AIM:** Trihalomethanes (THMs) are prevalent chemicals in drinking water (DW). Exposure is through ingestion, inhalation and dermal absorption and has consistently been associated with increased bladder cancer (BC) risk. We assessed THMs levels in DW and estimated the burden of bladder cancer in the European Union (EU). **METHODS:** We obtained annual mean THM levels in municipal DW in the 28 EU countries in 2010-2017 through a standardized questionnaire and calculated the population-weighted EU mean. We used published THM levels in countries where THM data was not provided for further imputations. We estimated the attributable BC cases following the burden of disease approach. The dose-response function was obtained from the largest international pooled-analysis on THM exposure and BC and was used to estimate the odds ratio for each country, with an alternative exposure scenario of <5µg/L. We calculated the country annual number of attributable BC cases using incidence rates from GLOBOCAN. **RESULTS:** The amount of data, representativeness and accuracy was heterogeneous among countries. Mean THM level in drinking water in EU-28 was 11.9µg/L (SD 11.1), ranging from 0.0µg/L (Denmark) to 66.2µg/L (Cyprus). The EU 28 average population attributable fraction was 4.6%, and the maximum was 24% in Romania (95%CI 13-34) and 23% in Cyprus (95%CI 12-33). In total, 5,708 (95%CI 2,940-8,318) annual BC cases were attributable to THM exposure in the EU (ranging from 0 in Denmark to 1,498 in Spain). If THM levels in DW were reduced to the EU mean of 11.9 µg/L among countries above this level, 2,438 (95%CI 1,287-3,469) cases of BC could be avoided annually in the EU. **CONCLUSIONS:** Although the country mean THM levels were below the legal limit (100µg/L), the attributable BC burden and related costs are considerable and can be further lowered by improvements in the quality of DW, especially in countries with higher THM levels. **Funding:** FP7 EXPOSOMICS Project and CIBERESP.

### **O03.02.48. Disinfection By-Products in Public Drinking Water Systems in Newfoundland and Labrador (Canada): A Population-Based Study for Assessment of the Environmental Health Risks**

Atanu Sarkar

*Brenda Greene<sup>1</sup>, Atanu Sarkar<sup>1</sup>*

*1. Community Health and Humanities, Memorial University, St. John's, NF, Canada.*

**Abstract:** Presence of disinfection by-products (DBPs) in public drinking water and associated health risks, such as cancers are the contentious issues in the province of Newfoundland and Labrador (Canada). However, there is no large population level study showing any association between exposure to DBPs and water infrastructure and cancer risks. The objectives of the study were to explore any association between DBPs levels in public water supplies and cancer rates in individual communities and population of the communities. Community-based DBPs levels (trihalomethanes (THMs) and haloacetic acids (HAAs)) (2010-2016) were collected from the provincial government's website. The gastrointestinal and genitourinary cancer data were obtained from the provincial cancer registry. Out of total 362,670 population (310 communities with 336 public drinking water supplies), 60,913 (17%) were considered exposed to DBP exceedances. Odds ratios for the rates of gastrointestinal and genitourinary, and combined cancer and THMs and HAAs exceedances (combined) were 1.31 (95%CI: 1.20-1.43), 1.21 (95%CI: 1.02-1.44) and 1.31 (95%CI: 1.21-1.42) respectively. However, HAAs exposure has a stronger association (than THMs) with gastrointestinal, genitourinary, and combined cancer. Of the 260 systems servicing small communities (<1000 residents), 44 experienced either THMs or HAAs exceedances, and 92 experienced both. Of the 53 systems servicing medium communities (1000-3999 residents), 13 experienced either THMs or HAAs exceedances, and 18 experienced both. In contrast, of the 23 systems servicing large communities (>4000 residents), 2 experienced HAA exceedances, and 3 experienced both. 61.40% of the 272 systems that rely on a surface water source some form of DBPs exceedance. While only 7.58% of the 66 systems that rely on a ground water source experienced any type of DBPs exceedance. Smaller communities with low revenues experienced more exceedances of DBPs and higher prevalence of related cancers.

S03.02A. A Data and Research Platform for Healthy Cities: The Canadian Urban Environmental (CANUE) Health Research Consortium

**S03.02.01. The Canadian Urban Environmental Health Research Consortium (CANUE) - Enabling Collaborative Multi-Factor Environmental Health Research**

Jeffrey Brook

*Jeffrey R. Brook<sup>1</sup>*

*1. Dalla Lana School of Public Health and Department of Chemical Engineering and Applied Chemistry, University of Toronto, Toronto, ON, Canada.*

Abstract: In 2015, the Canadian Institutes of Health Research (CIHR) called for a new national consortium that would bring together scientific and other expertise from a wide variety of disciplines and fields from academia, government, charities and industry, to focus on specific research priorities that can only be addressed through interdisciplinary and intersectoral research. This included developing a 'data and methodological hub' where environmental researchers could collaborate with cohorts and health researchers on focused health projects using innovative measurement models and 'analysis-ready' data. Responding to this call, the Canadian Urban Environmental Health Research Consortium (CANUE) was established and aims, through a coordinated program, to capitalize on Canada's growing big data capacity by facilitating the linkage of extensive geospatial exposure data to the wealth of established cohorts and administrative health data holdings (<http://canue.ca>). This presentation will provide an overview of CANUE's vision, structure, and related strategic plan, with a particular focus on successes and challenges during our first two years of operation and opportunities to advance environmental health research towards the goal of healthier urban populations.

## **S03.02.02. Developing an Environmental Exposure Data Platform for Urban Health Research**

Evan Seed

*Evan Seed<sup>1</sup>*

*1. Dalla Lana School of Public Health, University of Toronto, Toronto, ON, Canada.*

**Abstract:** An important part of the Canadian Urban Environmental Health Research Consortium's (CANUE) mandate is developing an operational urban environmental exposure data platform in support of population-based health research. An effective data platform is viewed as key to breaking down some of the existing research silos in the environment and health field and enabling investigation of multiple and interacting environmental influences on population health. In this presentation, we focus on summarizing the types of exposure data in our platform and those we are currently working on, along with how we manage data access and provide user support with value-added content, and custom data processing and visualization tools. In the early stages of developing content for the data platform our efforts focused on integrating data from different national-scale data sources already in existence, many of which were publicly available with published supporting documentation. Continuing efforts focus on developing new data metrics and integrating the many regional and city-specific or, so-called long-tailed data that make up most urban data sets. Our early experience in developing an environmental exposure data platform has provided valuable lessons learned and guided the operation and user support provided by CANUE. In this context, we discuss the data curation process, including data discovery and content selection when presented with multiple datasets. The lessons learned are aimed at data managers that must decide on the value of the data as well as adding value to the data through the curation process. Finally, we discuss some of the emerging challenges in building, sustaining, and future-proofing an environmental exposure data platform for urban health research.

### **S03.02.03. Emerging Methods for Developing and Working with Urban Environmental Exposure Data**

Mahdi Shooshtari

*Mahdi Shooshtari<sup>1</sup>*

*1. CANUE, Victoria, BC, Canada.*

Abstract: The increasing availability of data with high spatial and temporal resolution, from satellites to street-level images, presents opportunities to make use of machine learning to derive and describe characteristics of the built environment regionally and nationally. Once produced, these metrics are themselves large data sets, with data on 800,000 locations over multiple months and years. This presentation will provide illustrative examples of CANUE's approaches and tools for working with very large datasets to produce metrics of urban form, useful for environmental health research. Google Earth Engine enables the global-scale monitoring and measurement of changes in the environment by curating and managing historical and ongoing satellite data; and providing an easy to use analytical platform for creating and implementing scripts and algorithms to process the data into useful metrics of environmental characteristics and their change over time. We present an overview of how we use this platform to produce metrics of greenness and local climate zone classifications. Google Street View and Open Street View images contain a range of information that can be used for mapping micro-scale urban features, such as building and vegetation types. Here we describe machine learning approaches used by CANUE to identify features of interest and discuss some of the inherent strengths and weaknesses. The final exposure metrics held in the CANUE platform are large datasets. A single metric of annual average temperature is available for each of 800,000 postal codes, in each year of 1984-2016 inclusive, and monthly versions increase this volume twelve-fold. In other cases, the underlying data begin at an hourly resolution. Here we describe script-based tools for summarizing these data into aggregated exposures over time based on residential history, and into temporal trends by postal code.

#### **S03.02.04. Spatial and Temporal Changes in Urban Environmental Exposures: Practical Examples**

Dany Doiron

*Dany Doiron*<sup>1</sup>

*1. Research Institute of the McGill University Health Centre, Montreal, QC, Canada.*

Abstract: Since its launch, CANUE has assembled a dozen nationally standardized urban exposure metrics and is regularly integrating new regional and national datasets into its data holdings. These environmental exposure datasets can support comprehensive analyses of the spatial and temporal distribution of multiple exposures in large populations. This presentation will give an overview of selected exposure metrics currently held and disseminated by CANUE and their distribution in space and time. Spatial differences and temporal changes in area-level environmental exposures from the 1980s to today in Canada's three largest Census Metropolitan Areas (Toronto, Montreal, Vancouver) will be highlighted. For example, trends in postal code-level neighbourhood greenness over a 30-year period will be shown, with examples of areas with particularly large fluctuations. Changes in population-level exposure to air pollutants (nitrogen dioxide, ozone and fine particulates) and comparisons of walkability scores in these three cities will also be shown, highlighting areas favouring active living. The public health relevance of trends and differences in exposure metrics over time and space will be emphasized throughout.

### **S03.02.05. Emerging Evidence on Multi-Factor Associations between Urban Exposures and Health Outcomes: Practical Examples**

Dan Crouse

*Dan L. Crouse<sup>1</sup>*

*1. Sociology, University of New Brunswick, Fredericton, NB, Canada.*

**Abstract:** This presentation will showcase exemplary studies that have integrated CANUE exposure data with several large, Canadian, population-based health datasets. The first case study focuses on results from a large cohort study in which estimates of exposures to fine particulate matter (PM<sub>2.5</sub>), ozone, and nitrogen dioxide were assigned to subjects across Canada in the 1991 Canadian Census Health and Environment Cohort (CanCHEC). We examined associations between cause-specific mortality and exposure to these pollutants using single and multi-pollutant models. Our results suggest that exposure to PM<sub>2.5</sub> alone does not fully explain the risk of mortality associated with exposure to ambient pollution. A second case study presents results from a study investigating associations between risk of mortality and living in greener areas of Canada's 30 largest cities among subjects in the 2001 CanCHEC. Here, we used satellite-derived estimates of greenness, and adjusted our survival models for exposures to ambient air pollution (in addition to many personal and contextual characteristics). We found that increased amounts of residential greenness were associated with reduced risks of dying from several common causes of death. We found more protective effects among men (compared to women), and among those with higher incomes and with higher levels of education. Finally, a third case study describes an ongoing study in which we have linked data related to weather, ambient air pollution, and a community-level deprivation index to patients diagnosed with multiple sclerosis (MS) through the Canadian Chronic Disease Surveillance System and living in New Brunswick. Here we are exploring associations between several environmental exposures and spatial and temporal patterns of MS incidence.

## S03.02B. Empowering Vital Environmental Health and Exposure Research to Address Disasters and Emerging Threats

### S03.02.07. Importance of Exposure and Health Disaster Research

Linda Birnbaum

*Linda Birnbaum<sup>1</sup>, Aubrey Miller<sup>1</sup>*

*1. NIEHS, Research Triangle Park, NC, United States.*

**Abstract:** Responses to various disasters including the World Trade Center attack, Great Eastern Japan Earthquake, Gulf Oil Spill, Ebola and Zika outbreaks, Lac-Mégantic rail disaster, and recent hurricanes and wildfires have revealed the dire need for improved ability to perform rapid data collection and research for such events. In 2013, leaders from NIH, CDC, and HHS, noted that "the knowledge that is generated through well-designed, effectively executed research in anticipation of, in the midst of, and after an emergency is critical to our future capacity to better achieve the overarching goals of preparedness and response: preventing injury, illness, disability, and death and supporting recovery." While much has been done to improve the life-saving response for public health emergencies, these events have also revealed notable gaps in our ability to develop, coordinate, and implement needed scientific research in response to a disaster. It took 11 months to begin a longitudinal health study of exposed workers after the Gulf Oil spill. Such delays adversely affect the ability to identify participants or gather vital information to determine disaster-related risk factors such as resiliency, health outcomes related to exposures or other stressors, or efficacy of various response activities. Critical data are lost if not collected in a timely, systematic, and scientifically rigorous manner through coordinated interdisciplinary efforts with multiple stakeholders, including impacted communities. In response, the NIH Disaster Research Response Program was created to facilitate time critical data collection and research into national response and recovery efforts. Together with Canada and Japan, progress is being made to overcome some of the challenges and advance disaster research capabilities including availability of research protocols, IRB review processes, coordination among government agencies, and engagement of academic, public health, and community stakeholders.

### **S03.02.08. Applied Epidemiology and Exposure Challenges in Response to the Gulf Oil Spill**

Richard Kwok

*Richard Kwok<sup>1</sup>, Aubrey Miller<sup>2</sup>, Lawrence Engel<sup>3</sup>, Matt Curry<sup>4</sup>, Steven Ramsey<sup>4</sup>, Linda Birnbaum<sup>2</sup>, Dale Sandler<sup>1</sup>*

*1. Epidemiology, NIEHS, Research Triangle Park, NC, United States.*

*2. NIEHS, Bethesda, MD, United States.*

*3. Epidemiology, UNC-Chapel Hill, Chapel Hill, NC, United States.*

*4. Social & Scientific Systems, Inc., Durham, NC, United States.*

Abstract: Each environmental or man-made disaster presents unique challenges for studying potential health consequences. Nonetheless, valuable lessons from studying a single disaster can inform approaches following other disasters. The 2010 Gulf of Mexico Deepwater Horizon disaster created the largest marine oil spill in history. Individuals who worked on the clean-up of the spill were exposed to toxicants, stressors, and other environmental factors that could affect health. In 2011, NIEHS initiated The Gulf STUDY (Gulf Long-term Follow-up Study) to investigate a wide range of chemical and non-chemical exposures and potential physical and mental health effects. Study participants participated in clean-up or attended worker safety training. Cohort enrollment involved telephone interviews, followed by a home exam for Gulf coast residents. Most participants enrolled long after active clean-up had ended. The findings from the study may inform public health responses in Gulf communities and/or responses to future oil spills. This discussion will highlight the issues and challenges of gathering information quickly to inform the design of a large-scale prospective cohort study of over 32,000 individuals involved in the 2010 Gulf Oil Spill response and clean-up efforts. Such challenges include: Administrative and ethical approvals, uncertainty due to lack of coordination between response and research organizations, utilizing data collected for non-research purposes, enrolling large numbers of participants from impacted communities, and conducting complex clinical measurements in atypical environments, while at the same time striving to ensure high quality data, transparency, and communications.

### **S03.02.09. Development of the NIH Disaster Research Response (DR2) Program and Ongoing Efforts in the U.S.A.**

Abstract: Responses to various disasters and emerging threats have revealed the dire need for improved ability to perform rapid data collection and research for such events. As such, the National Institutes of Health Disaster Research Response Program (DR2) was created to build and promote tools, processes, and relationships to collect vital exposure and health information in response to environmental disasters. The DR2 Program, a collaborative effort between the National Institute for Environmental Health Sciences and the National Library of Medicine, reduces the time required to deploy a public health research response after disasters by providing access to over 345 online publicly available data collection tools and information. Metadata was also developed to help researchers review and understand the utility of the various tools for differing situations. Additionally, a novel human subject reviewed protocol that can be rapidly modified and used for future disaster situations has been developed. This protocol includes the ability to perform medical testing and collection of exposure data, including biospecimens. National workshops, large-scale tabletop exercises, and new networks linking academia, public health officials, and impacted communities have also been created to test initiatives, address ethical considerations and Institutional Review Board issues, and to implement environmental health and exposure research in response to emergencies. As such, the research community is now poised to begin moving into a new era of strategic science as part of disaster response efforts. This presentation will facilitate understanding of common barriers in disaster research and strengthen awareness of efforts to improve our collective capacity to perform time critical human health and exposure assessments to support decision-making and improve preparedness, response, and recovery efforts.

### **S03.02.10. Disaster Response Research Development in Japan**

Shoji Nakayama

Abstract: Japan is a country of natural disasters and many lessons have been learnt in the past. The Disaster Medical Assistant Team (DMAT) system is one of those. After the 11 March 2011 Great Eastern Japan Earthquake and Tsunami, Japan experienced unprecedented disturbance of people's life including destruction of infrastructures, mass evacuation and collapse of communities. Everything went mess from immediate shortage of life supporting facilities to loss of future prospects. The importance of the unified command system is also a lesson learned from the past disasters such as the Kobe earthquake. However, there is still a gap in tools for decision makers to acquire timely information about public health status of affected areas. For example, there are no standardised tools to evaluate the consequences of long-term evacuation on emotional and physical health. The lack of such epidemiological instruments makes it difficult to perform evidence based public health. Absence of such tools may also have hampered the participation of public health specialists into disaster response teams. In Japan, the government moved to establish a public health response team, namely Disaster Health Emergency Assistance Team or DHEAT, in order to quickly provide prompt public health services during and after the disaster. To add an environmental component to such an effort, the National Institute for Environmental Studies started a programme to implement epidemiological tools that can be readily used from immediately after the disaster onset to decades long recovery periods for assessing general and specific environmental exposures and their effects on affected people. This presentation will focus on the Japanese endeavour to develop disaster epidemiology tools and its collaborative works with the US National Institute of Environmental Health Sciences.

### **S03.02.11. Disaster Research Response Development in Canada**

Tom Kosatsky

*Marc Lafontaine<sup>1</sup>, Tim Singer<sup>1</sup>, Tom Kosatsky<sup>2</sup>*

*1. Health Canada, Ottawa, ON, Canada.*

*2. BC CDC, Vancouver, BC, Canada.*

Abstract: The 2016 Alberta wildfires, which destroyed entire neighbourhoods of urban Fort McMurray and the 2013 Lac-Mégantic, Québec train derailment and explosion illustrate that Canadian communities are not immune to environmental public health (EPH) disasters. Disasters expose the population, responders and volunteers to a range of contaminants and stressors, which may harm physical and mental health. When disasters strike, the initial focus is on life saving interventions such as clinical care and measures aiming at minimizing population exposure including evacuation, sheltering in place and do-not-consume advisories. Afterward, attention shifts toward community re-entry, rehabilitation and health studies to address potential delayed and long-term health effects. Exposure science and environmental epidemiology resources can play a vital role in supporting response authorities to reduce the health risks from the release of hazardous chemicals. They may contribute to the timely identification, determination of concentrations and dispersion of released substances, designing questionnaires and initiating registries, and evaluating the value of biological sampling. Further, EPH disasters typically offer a brief window of time to collect ephemeral exposure data, biospecimens and to start scientific research that could improve both health outcomes and capabilities for future response. This discussion will highlight the efforts of the Canadian Disaster Research Response (CanDR2) Steering Committee to develop a Pan-Canadian framework aiming at enhancing the integration of EPH scientific and research assets into disaster management. Three EPH focus areas will be presented: (1) Establishing a disaster response community of practice or network (2) Generating and transferring disaster knowledge, and (3) Enhancing timely data sharing, sample collection and health research execution.

## S03.02C. Environmental Justice and Women's Health

### **S03.02.13. Digital Daily Logs: A Novel Method for Collecting Acute Health Symptoms in an Environmental Justice Neighborhood Adjacent to Active Oil Drilling**

Bhavna Shamasunder

*Bhavna Shamasunder<sup>1</sup>, Marissa Chan<sup>2</sup>, Noa Batia Molshatzki Ben-Ari<sup>4</sup>, Sandy Navarro<sup>3</sup>, Sandrah Eckel<sup>4</sup>, Jill Johnston<sup>4</sup>*

- 4. Department of Preventive Medicine, University of Southern California, Los Angeles, CA, United States.*

**Abstract:** Los Angeles is the largest urban oil field in the United States and one of the most oil rich basin in the world. In low-income neighborhoods of color with cumulative vulnerabilities (such as greater linguistic isolation and higher percentages of renters), active drilling occurs much closer to homes, schools, playgrounds, and other sensitive land uses with fewer protections such as emissions control equipment and covered fields. In collaboration with a community-based network of promotoras, (community health workers), we assessed the ability to collect daily acute symptoms and well-being information using a phone-based platform among predominantly Latino residents in South Los Angeles living within 500m of an oil well. Here, we describe the process to develop a bilingual daily digital health log. Using a text messaging system, we aimed to pilot a mixed methods approach to log information about health and social stressors. Our research was informed by a prior community health survey that supported community research capacity building within promotora networks (Shamasunder et al, 2018). 113 people participated in the 7-day study with a 77% response rate (n=87). 76% of study respondents were women. In the preliminary analysis, we coded qualitative reports on stress from the daily logs among participants. Responses to digital daily logs indicate responses within individuals change daily. Women note a greater number and variety of stressors. Stress was associated with reports of headaches, anxiety, fatigue, work, and lack of work. Residents' concerns over children's schooling was a top concern. Social stressors may make residents more vulnerable to impacts of pollution. Headaches, for example, have been associated with oil extraction, and were ascribed by residents to other life stresses. This novel approach can help facilitate collection of symptoms and stress data in an environmental justice community.

### **S03.02.14. The COSECHA Study: Youth Peer-To-Peer Research on Pesticide Exposure in a Farmworker Community**

Kim Harley

*Kim G. Harley<sup>1</sup>, Robert Gunier<sup>1</sup>, Asa Bradman<sup>1</sup>, Chloe Lessard<sup>1</sup>, James Nolan<sup>1</sup>, Kim Anderson<sup>2</sup>, Carolyn Poutasse<sup>2</sup>, David Camann<sup>3</sup>, Alice Yau<sup>3</sup>, Jose Camacho<sup>4</sup>, Kimberly Parra<sup>4</sup>*

- 4. Clinica de Salud del Valle de Salinas, Salinas, CA, United States.*

**Abstract:** Background: Seven million pounds of pesticides identified as possible carcinogens or endocrine disruptors are applied annually in California, but there is little data on how adolescent girls in agricultural communities may be exposed. Methods: We conducted a youth empowerment project to measure pesticide exposure among 100 14-16 year old Latina girls living in the agricultural Salinas Valley, CA. Pesticide concentrations were measured in silicone wristbands worn by participants for one week and in house dust. High school students (N=10) hired as youth research assistants collected the data and were engaged in study design, implementation, and dissemination. Results: Compounds detected in wristbands and dust included agricultural-use, residential-use, and now-banned pesticides. Commonly detected pesticides in house dust were permethrin, carbaryl, chlorothalonil, and fipronil. Fipronil compounds and permethrin were also widely detected in wristbands. Living within 100m of an agricultural field was associated with higher concentrations of dacthal and permethrin in wristbands and higher permethrin in house dust. Pesticide products in the home and using an exterminator were associated with higher permethrin in wristbands and dust. Participants with door mats in their home entryway had significantly lower concentrations of cypermethrin, permethrin, fipronil sulfide, and DDE in their wristbands and lower concentrations of cypermethrin in their dust. Discussion: This youth-led study characterizes pesticide exposure to adolescent Latina girls and suggests methods for reducing exposure. The youth researchers have developed innovative educational messaging, including puppet shows, videos, and radio dramas; taught residents to access information about local pesticides use; and plan to distribute door mats and develop educational murals to share results and minimize future exposures.

### **S03.02.15. Community- and Discovery-Driven Exposure Science in the Women Firefighter Biomonitoring Collaborative**

Rachel Morello-Frosch

*Rachel Morello-Frosch<sup>1</sup>, Jessica Trowbridge<sup>1</sup>, Roy Gerona<sup>2</sup>, Ruthann Rudel<sup>3</sup>, Heather Buren<sup>4</sup>, Anthony Stefani<sup>5</sup>*

- 5. San Francisco Firefighter Cancer Prevention Foundation, San Francisco, CA, United States.*

Abstract: Occupational studies indicate that firefighters are at higher risk for different types of cancers than the general population, and concern has mounted about elevated rates of premenopausal breast cancer among women firefighters. The Women Firefighters Biomonitoring Collaborative (WFBC) is a community-based participatory research project analyzing exposures to environmental chemicals linked to breast cancer among female firefighters in San Francisco (SF) compared to non-firefighters. As scientific partners in the WFBC, women firefighters have been involved in study design, data collection, and results communication. Between 2013 and 2014 we recruited 86 women firefighters and 84 office workers employed in San Francisco, conducted an exposure assessment interview, and collected blood samples. We conducted targeted analysis for 12 perfluoroalkyl substances (PFAS) using liquid chromatography-tandem mass spectrometry. We detected seven compounds in over 70% of participants at levels above the level of detection (LOD 0.02-0.05 ng/ml), five of which were detected in 98 -100% of participants. Multivariate models showed that firefighters had a 1.53 and 2.19 times higher concentration of PFNA and PFHxS respectively, compared to non-firefighters. Among firefighters only, multivariate models showed increased concentration of PFNA, PFOA, PFOS and PFUnDA for firefighters aged 50 years or older, and higher PFOA levels among firefighters who reported ever using firefighting foam. Additionally, PFHxS levels were higher among those who "rarely" used personal protective equipment (PPE) compared to those who reported "always/often" using PPE. Our results indicate that women firefighters have higher levels of some PFAS compared to office workers, and that these exposures may be associated with firefighting foam and PPE use. Further research is needed to understand the health implications, particularly for breast cancer risk, of these exposures.

### **S03.02.16. Air Pollution and Gynecologic Disease Outcomes: Infertility, Menstrual Irregularity, Uterine Fibroids, and Endometriosis**

Jaime Hart

*2. Environmental Health, Harvard T.H. Chan School of Public Health, Boston, MA, United States.*

Abstract: While issues of environmental justice have highlighted populations at high risk of adverse health outcomes due to air pollution, chemical exposures, and land use, how these disparate exposures might uniquely impact women's health is an area of emerging research interests. Women may be particularly vulnerable in different ways than men; in that, socially- and culturally-patterned exposures may lead to different exposure patterns in women. Sex differences in biological processes can also play a role in how chemical exposures could differentially impact the health of women compared to men. Further exacerbating these differences are how sex intersects with race, class, or gender to impact both environmental exposures and downstream biological effects on disease outcomes in women. This interaction between social, environmental, and biological factors may place vulnerable subpopulations of women, such as Hispanic or African-American women, at a disadvantage with respect to disease risk. We will highlight the growing body of research of the effects of air pollution on female reproductive outcomes and infertility, and the implications of these findings among vulnerable populations.

### **S03.02.17. Environmental Phthalates Exposure and Measures of Uterine Fibroid Size among a Racially Diverse Population of Premenopausal Women**

Ami Zota

*Ami R. Zota<sup>1</sup>, Ruth J. Geller<sup>1</sup>, Antonia Calafat<sup>3</sup>, Cherie Q. Marfori<sup>2</sup>, Gaby Moawad<sup>2</sup>*

*2. Obstetrics and Gynecology, George Washington University, Washington, DC, United States.*

*3. National Center for Environmental Health, Centers for Disease Control and Prevention, Atlanta, GA, United States.*

**Abstract:** Background. Etiology of uterine leiomyoma (fibroids) is poorly understood. Endocrine disruptors, such as phthalates, may contribute to fibroid pathobiology because ovarian hormones are critical to fibroid growth. Objectives. We examined the association between phthalates exposure and two measures of fibroid size: diameter of largest fibroid and uterine volume. Study Design. We conducted a cross-sectional study of 61 premenopausal women undergoing surgery for their fibroids between 2014-2017 in an urban academic hospital in Washington DC. Spot urine samples were collected during a pre-operative clinical visit and analyzed for 14 phthalate metabolites and two non-phthalate plasticizer metabolites using mass spectrometry. Information on fibroid and uterine characteristics was obtained from MRI and/or ultrasound imaging. We examined associations with individual biomarkers, metabolite sums by parent compounds, and a potency-weighted sum of antiandrogenic phthalates ( $\Sigma$ androgen-disruptor). Size of the largest fibroid and uterine volume were modeled as dichotomous outcomes (divided at the median) using logistic regression adjusting for age, race/ethnicity, BMI, and time since diagnosis. Results. The majority of the sample was African American (63.9%), overweight or obese (75.1%), and had completed college or graduate school (68.3%). In multivariate models, women with higher concentrations of di(2-ethylhexyl) phthalate (DEHP) and diisononyl phthalate (DiNP) metabolites, and  $\Sigma$ androgen-disruptors had significantly greater uterine volumes compared to women with lower concentrations.  $\Sigma$ DEHP metabolites and  $\Sigma$ DiNP metabolites were associated with 3.05 (95% CI 1.08-8.63) and 1.87 (95% CI 1.07, 3.29) increased odds of greater uterine volume, respectively. Conclusions. In this preliminary study, exposure to some phthalates was associated with larger uterine volume, a marker of disease severity and fibroid growth. Larger, prospective studies are needed to confirm these relationships.

### **S03.02.18. Urinary Paraben Concentrations and Pregnancy Glucose Levels among Women from a Fertility Clinic**

Tamarra James-Todd

*Andrea Bellavia<sup>1</sup>, Yu-Han Chiu<sup>1</sup>, Lidia Minguez-Alarcón<sup>1</sup>, Jennifer Ford<sup>1</sup>, Myra Keller<sup>1</sup>, John Petrozza<sup>2</sup>, Xiaoyun Ye<sup>3</sup>, Antonia Calafat<sup>3</sup>, Russ Hauser<sup>1</sup>, Tamarra James-Todd<sup>1</sup>*

*1. Environmental Health, Harvard T.H. Chan School of Public Health, Boston, MA, United States.*

*2. Massachusetts General Hospital, Boston, MA, United States.*

*3. Centers for Disease Control and Prevention, Atlanta, GA, United States.*

**Abstract:** Background: A number of endocrine disrupting chemicals (EDC) are associated with gestational diabetes (GDM) risk factors. Few studies, however, have investigated the association between pregnancy exposure to parabens, a class of widely used EDCs, and pregnancy glucose levels—a risk factor for GDM. Furthermore, little is known about this association in subfertile women—a group at high risk of GDM. Methods: Using a prospective cohort study, 241 women from the Environment and Reproductive Health (EARTH) Study had data available on 1st and/or 2nd trimester urinary methyl- (MP), butyl- (BP), and propyl-paraben (PP) concentrations, as well as late 2nd trimester glucose levels from the GDM screening test. Trimester-specific associations between MP, BP, PP, and pregnancy glucose levels, were first evaluated in separate statistical models. Paraben mixtures were also assessed using mutual adjustment, as well as Bayesian Kernel Machine Regression (BKMR), a recently proposed method for chemical mixtures that flexibly models the joint effect of chemicals in a non-parametric fashion. Results: When assessed individually, we observed positive associations between BP at both 1st and 2nd trimesters, and late 2nd trimester glucose levels (e.g comparing the 4th and 1st quartile, respectively:  $\beta=7.8$  mg/dL; 95% CI:-2.9, 18.6;  $\beta=10.6$  mg/dL; 95% CI:0.7, 20.5). When investigating paraben mixtures, we found a positive association between 1st trimester BP and glucose ( $\beta =10.2$  mg/dL; 95% CI:0, 20.4) and a suggestive negative association between 1st trimester PP and glucose ( $\beta =-13.9$  mg/dL; 95% CI: -30.4, 2.6). We observed no evidence of interaction among parabens. Conclusion: We found concentrations of BP when assessed individually and as a mixture to be positively associated with glucose levels. Given the wide-spread use of parabens in consumer products, certain parabens may dysregulate glucose levels during pregnancy, with implications for GDM risk.

S03.02D. Omics in Environmental Epidemiology for Understanding Current Environmental Health Issues

**S03.02.19. Using Molecular -Omics in Environmental Epidemiology to Gain Unique Insights into Environmental Health**

Todd Everson

*Todd M. Everson<sup>1</sup>, Carmen J. Marsit<sup>1</sup>*

*1. Environmental Health, Emory University, Atlanta, GA, United States.*

**Abstract:** The incorporation of molecular -omics data into environmental epidemiology allows environmental health researchers to answer novel questions about how our environment influences health and disease. Although molecular data have been consistently utilized in experimental biological research, the the rapid growth and development of -omics technologies is making genomics, epigenomics, transcriptomics, proteomics, metabolomics and microbiomics increasingly accessible to epidemiologic research. These technologies allow for the interrogation of hundreds of thousands to millions of molecular features in a highly reproducible and cost-effective fashion in human samples, and the incorporation of these tools into environmental epidemiology has enabled the field to investigate how the environment impacts human health in novel ways. In turn, these features can form useful biomarkers of exposure-response relationships, inform us about toxic mechanisms and modes of action, and contribute to causal reasoning. However, incorporating these types of data into epidemiologic research comes with many challenges, including having to consider tissue-specific responses to stressors, dealing with technical artifacts, how and whether to adjust for tissue heterogeneity, and limiting the possibility of false positives while allowing for the discovery of true positive findings. I will present an overview what genomics, epigenomics, transcriptomics, proteomics, metabolomics and microbiomics can add to environmental health research, and recent advancements in the field to deal with the potential challenges of doing so.

## **S03.02.20. Assessing the Influence of in Utero Co-Pollutant Exposures on Transcriptomic Networks and Birth Outcomes**

Maya Deyssenroth

*Maya Deyssenroth<sup>1</sup>, Chris Gennings<sup>1</sup>, Shelley H. Liu<sup>1</sup>, Shouneng Peng<sup>1</sup>, Ke Hao<sup>1</sup>, Luca Lambertini<sup>1</sup>, Brian P. Jackson<sup>2</sup>, Margaret R. Karagas<sup>2</sup>, Carmen J. Marsit<sup>3</sup>, Jia Chen<sup>1</sup>*

*1. Icahn School of Medicine at Mount Sinai, New York, NY, United States.*

*2. Dartmouth College, Hanover, NH, United States.*

*3. Emory University, Atlanta, GA, United States.*

Abstract: Multiple studies have linked intrauterine exposures to birth outcomes. However, inconsistencies in the literature persist. While heterogeneity in study conditions likely play a role, the discrepancy in reported findings may also reflect a focus on assessing the isolated effect of individual pollutants. Such methods fail to account for the presence of co-pollutants that may alter the activity of the specific exposure under consideration. The molecular pathways through which environmental exposures exert their effects have not been clearly delineated. However, it is suggested that in utero toxicant exposures may induce aberrations in processes mediated by the placenta, the organ overseeing appropriate fetal development. Alterations in the expression and methylation of several placental loci, including genes involved in nutrient transport, endocrine signaling and imprinting, have been linked to birth outcomes. However, similar to studies linking pollutants to birth outcomes, molecular biomarker studies largely focus on univariate associations between individual genes and health effects. High-throughput assessments of environmental exposures and molecular markers are becoming increasingly available to better capture the relationship between toxicant exposures, affected molecular processes and health effects within an environmental epidemiology context. To take advantage of this rich resource, however, methodologies need to be developed that not only account for the complexity but also facilitate integration across datasets. Here, we motivate the application of novel statistical and bioinformatics-based approaches, including environmental mixture modeling methods and gene coexpression networks, to gain insight into the inter-relationship among intrauterine trace metal exposure, placental gene activity and fetal growth.

### **S03.02.21. The Epigenome and In-Utero Environmental Exposures**

Mariona Bustamante

*Mariona Bustamante<sup>1</sup>, Todd M. Everson<sup>5</sup>, Marta Vives<sup>2</sup>, Johanna Lepeule<sup>3</sup>, Martine Vrijheid<sup>1</sup>, Marie-France Hivert<sup>4</sup>*

Abstract: The epigenome is defined as the network of chemical marks that regulate the function of the genome. The epigenome receives the signals from the genome and from the environment to produce a homeostatic response, and therefore it is dynamic and tissue specific. DNA methylation is the epigenetic mark most extensively studied in epidemiological designs. Environmental insults can leave a fingerprint on DNA methylation, particularly those that occur prenatally, which might persist and be connected to disease later in life. We will highlight recent findings from the Pregnancy and Childhood Epigenetics (PACE) consortium and the HELIX (Human Early Life Exposome) project on maternal tobacco smoking during pregnancy and other environmental factors to illustrate the link between in-utero environmental exposures, DNA methylation and disease. Maternal smoking during pregnancy has been associated with differential methylation at thousands of CpGs in cord blood, with some of them persisting into childhood, and this signature was successfully used to develop a biomarker of exposure. Interpreting the results from epigenetic epidemiology studies can be complicated due to the tissue specificity of epigenetic responses, and the complex relationship between DNA methylation and gene expression. For instance, we observed that maternal smoking sensitive CpGs in cord blood and placenta are markedly different, likely related to the unique ways through which these two tissues process and respond to toxic exposures. The challenges of the epigenomics in environmental health research for the next years will be discussed, including: sample size and collaboration in consortia, resolution of current DNA methylation arrays, assessment of other epigenetic marks, access to the target tissue, controlling for cellular heterogeneity, analysis of longitudinal data, and integration of different molecular layers to interpret findings.

## **S03.02.22. The Exposome and the Developmental Origins of Lifelong Health: Pre-, Peri- and Postnatal Microbiome & Metabolome Development**

Juliette Madan

*Juliette C. Madan<sup>1</sup>, Anne G. Hoen<sup>2</sup>*

*1. Pediatrics, Geisel School of Medicine at Dartmouth, Hanover, NH, United States.*

*2. Epidemiology, Geisel School of Medicine at Dartmouth, Hanover, NH, United States.*

Abstract: The roles of human-associated microbial communities in health are appreciated, but we lack a mechanistic understanding of the differences between health promoting or dysbiotic/detrimental microbial communities and how the microbiome develops over time. Large scale epidemiological studies of environmental toxicants and their impact on human health benefit from thorough investigation of the bidirectional relationship between toxicants and the human microbiome/metabolome. Ultimately, the effects of microbial communities on health outcomes is particularly evident in the pre-, peri-/post and neonatal period during the critical window of microbial training of the developing immune system. Data generated by us and others indicate that microbial community development and metabolism can be influenced by coexisting microbes in often unexpected ways, and we hypothesize that these networks of microbial metabolic interactions drive community development and function. In our Children's Center at Dartmouth, we combine targeted microbial sequencing, metagenomics and metabolomics analyses, computational methods, and laboratory-based studies to identify microbial community structures over time, and microbe-produced metabolites that influence community development and stability. Our group investigates the relationships between exposures (e.g. environmental toxicants such as arsenic, dietary exposures, medications/antibiotics, delivery mode), the developing microbiome and metabolome in pregnancy, infancy and early childhood, and associations with health outcomes in a large molecular epidemiological study of 2,000 mother-infant dyads (4,000 subjects), the New Hampshire Birth Cohort Study. Our long-term goal is to rigorously test associations between microbiome development, community metabolism and host physiology, and to apply this knowledge to the discovery of strategies for health promotion.

### **S03.02.23. Metabolomics, Complex Exposures, and Multi-Omics Integration**

Shuzhao Li

*Shuzhao Li<sup>1</sup>*

*1. Dept. Medicine, Emory University, Atlanta, GA, United States.*

Abstract: The revolutionary capability of modern mass spectrometry enables ultra high-resolution metabolomics, which embodies the 2nd golden age of biochemistry since the delineation of major metabolic pathways. These metabolomics data capture endogenous metabolites, dietary intake, pharmaceutical drugs and environmental pollutants, and serve as a key middle layer between genome and environment. Using metabolome-wide association studies, we start to gain mechanistic insights of health impact by environmental exposure. Our mummichog algorithm further brings untargeted metabolomics to pathway and network interpretation. We will present examples on environmental epidemiology, disease studies and multi-omics integration.

## S03.02E. Why is My Sensor Not Working? - Making Sense of Sensor Technologies for Environmental Exposure and Health Studies

### **S03.02.25. Moving Towards an Adaptable Laboratory and Field Testing Protocol for Evaluating Sensor Performance**

Benjamin Barratt

*Benjamin Barratt<sup>1</sup>*

*1. King's College London, London, United Kingdom.*

**Abstract:** The potential for sensors to revolutionize environmental assessment and public engagement has been recognized for some time, however, initial enthusiasm has been blunted by disappointing outcomes, often arising from inappropriate use and/or unrealistic expectations. To move forward, industry, academia and the public require a transferrable "quality mark" for sensor performance indicating a technology's applicability for use in various settings. The aim of this symposium workshop is to stimulate discussion and ideas to ensure more robust outcomes in sensor deployment scenarios. This opening presentation will set the scene by describing the requirements for the development of an internationally recognizable laboratory and field testing protocol for environmental sensors. It will include a review of ongoing initiatives in Europe and North America, including their strengths and weaknesses. The London Air Quality Network Sensor Evaluation Protocol (LAQN-SEP) is one example of a protocol developed to meet the needs of research and citizen science in London. It incorporates a series of defined tests utilizing fixed reference-grade instruments and well-characterized portable monitors, allowing field evaluation of sensor performance in stationary and mobile deployments, including microenvironments. The LAQN-SEP is now being extended to allow independent testing of sensors by manufacturers through secure access to testing infrastructure. This will allow rapid and repeat evaluation against high cost reference monitors with minimal overhead from the host organization. While environmental sensor testing protocols are being developed in many countries, many of these are based on existing protocols developed for hardware-based systems. There is the risk that these will be too inflexible or costly to react to the rapidly changing world of software-based systems. Through discussion between a wide range of users and developers, it is hoped that these pitfalls will be avoided.

### **S03.02.26. Are Low-Cost Sensors Ready for Prime Time? The Case of Mobile Monitoring**

Joshua Apte

*Joshua S. Apte<sup>1</sup>, Kyle Messier<sup>1</sup>*

*1. Civil, Architectural and Environmental Engineering, University of Texas at Austin, Austin, TX, United States.*

**Abstract:** Lower-cost air pollution sensors offer the potential to dramatically increase the density with which air quality is monitored, thereby filling critical gaps in exposure assessment. One possible application for low-cost sensors is their use for mapping air quality when mounted on fleet vehicles such as taxis, buses, or delivery vans. However, mobile sensor deployments present unique challenges. When measuring on a rapidly moving platform, a high sampling rate ( $\sim 1$  Hz) may be desirable to capture spatial variability in air quality. Additional measurement challenges include vibration, wind, and frequent shifts in concentration, temperature, and humidity. We conduct a simulation study to consider the extent to which common performance limitations of available sensors might present challenges for mobile monitoring. As a starting point, we employ a rich dataset of measurements collected using two Google Street View cars specially equipped with reference grade instruments to measure NO, NO<sub>2</sub>, and black carbon. The measurements consist of  $\sim 2$  y of repeated observations (20-50 times) on every street in a 30 km<sup>2</sup> of Oakland, CA. To simulate the performance limitations of lower-cost sensors, we systematically degrade the performance of reference grade measurements and compare the resulting air quality maps to the reference dataset. We consider the following performance degradation scenarios: reduced sampling frequency, increased averaging time, randomly distributed noise (reduced precision), and serially correlated errors (drift). Our simulations suggest that an air quality mapping approach with repeated observations can be surprisingly robust to these common types of measurement degradation.

### **S03.02.27. Ensuring Trustworthy Data for Communities Engaged in Environmental Sensing**

John Volckens

*John Volckens<sup>1</sup>*

*1. Colorado State University, Fort Collins, CO, United States.*

**Abstract:** The recent proliferation of low-cost air quality sensors has sparked much interest among scientists, policymakers, and the general public. These sensors have enabled measurements at unprecedented spatial and temporal scales, which, in turn, has led to the creation of distributed networks to support both traditional research and community-based studies. Low-cost sensors also show promise for the emerging field of citizen-science and for application in resource-limited environments. With these exciting prospects, however, come challenges of sensor performance, reliability, data management, and communications/messaging to various stakeholders. This presentation will summarize our research on the development, evaluation, and application of sampling and sensor technologies for exposure and health research. Our group has pioneered the development of several devices for assessing human exposure to particulate matter air pollution (i.e., the UPAS, AMAS, OAS instruments). We have deployed these technologies for epidemiologic research on children and adults, for citizen-science research at the individual and community level, and for stakeholder-driven assessment of air quality in distinct microenvironments. This presentation will summarize prospects and pitfalls associated with real-time and time-integrated data collection, with the choice of low-cost vs. reference-grade measurement devices, with data management/quality (and data protection), and with communicating and working with members of the community (i.e., non-scientists). We will conclude with some discussion on the topic of matching the measurement to the research question of interest and on the potential for disconnects/misalignment between the exposure and epidemiologic research communities.

## **S03.02.28. Strategies for Sensor Deployment to Reduce Bias in Environmental Exposure and Health Studies**

Jill Baumgartner

*Jill Baumgartner*<sup>1</sup>

*1. McGill University, Montreal, QC, Canada.*

Abstract: Environmental sensing technologies are rapidly advancing. In particular, low-cost air pollutant measurement and health tracking techniques are emerging and existing techniques are becoming more compact and adapted for field deployment. However, field implementation of environmental sensors has proven challenging across many settings, study sizes and study designs, particularly when multiple stakeholder groups are involved in data collection and their interpretation. The proposed presentation will be the fourth in a symposium on the selection and use of sensing technologies for exposure and health studies and related challenges. This presentation will proceed sessions on sensor performance evaluation and validation processes, and aim to present recent examples of novel use of low-cost sensors for environmental intervention and policy evaluation and epidemiologic research. I will incorporate recent examples from my groups work on the integration of both models and sensors in health and exposure studies of household and ambient air pollution. This presentation will aim to facilitate discussion among symposium attendees about strategies to scale up environmental sensing for application in environmental health studies. In particular it will highlight the measurements trade-offs for researchers to consider in sensor selection and implementation, and the implications for measurement error and other types of bias in health studies.

### **S03.02.29. Sensor Selection and Scaling Up Mobile Monitoring for High-Resolution Mapping of Community Air Quality: Design Considerations in the MOV-UP Airport Ultrafine Particle Study**

Edmund Seto

Abstract: As novel environmental monitoring and exposure sensing approaches evolve, there is still the need to match the air quality concerns of communities with appropriate measurements. Designing an appropriate measurement approach for exposure studies requires identifying the sources of greatest concern, the set of pollutants that best characterize these sources, and sampling in manner that quantifies variations in concentrations in space and time. Recently, for the new Mobile Observations of Ultrafine Particles (MOV-UP) study, a sampling plan was designed to characterize ultrafine particle levels in communities near the SeaTac International Airport in Seattle, WA. Because of the need to cover a large area of approximately 250 km<sup>2</sup> with a limited instrument and staffing budget within the timeframe of a year, a mobile monitoring approach was chosen, in which two instrumented vehicles would collect ultrafine particle measurements along local roads that transect the flight paths of the airport. Mobile monitoring would allow coverage of the large area with a relatively small number of high-end ultrafine particle counters. In addition to measuring ultrafine particle concentrations for the MOV-UP study, there was also a need to distinguish between ultrafines sourced from roadway traffic versus those from aircraft. GPS data were used to identify driving on major roadways, and were supplemented by additional measurements of ultrafine particle size and black carbon levels to help discriminate between roadway and aircraft sources. A principal component analysis (PCA) yielded multivariate eigenvalues representative of the different sources of concern. Also, relating flight patterns with wind patterns may also help to identify ultrafine particle levels attributable to aircraft.

### **S03.02.30. A One-Dollar Passive Sensor for Black Carbon Monitoring: Capturing the Blackening**

*2. Axon Engineering, Seattle, WA, United States.*

**Abstract:** Background Black carbon (BC) is a major constituent of fine particulate matter (PM<sub>2.5</sub>), which is the largest environmental health risk worldwide, according to the Global Burden of Disease. BC is also associated with climate change because it is light-absorbing. Low-cost and ultra-low-cost sensors offer the potential to radically increase the quantity of environmental data (relative to using conventional sensors), though potentially at lower quality per datum. Research question Can an ultra-low-cost sensor (marginal cost per new measurement: under ten U.S. dollars) reliably measure long-term average indoor BC concentrations? Methods We designed and prototyped several ultra-low-cost sensors, and tested them in a laboratory and in the field in India. Like most BC sensors, our approach is based on the blackening of a white surface, which causes a change in the reflectance / absorbance of light incident to that surface. The resulting information reflects a time-integrated measure. We selected only designs that can be left in place for weeks or months, thereby shedding light on long-term average conditions. Data analyses test for reproducibility and limit of detection Results We employed two ultra-low-cost designs: one active, one passive. Maintenance is not required for the passive sampler and is minimal for the active sampler. Preliminary results indicate a high degree of reproducibility (correlation among duplicate samples: >0.9) and a limit of detection that would correspond to ~ a few weeks in a highly polluted environment (e.g., in a low-income household that burns solid fuels).

### **S03.02.31. The Application of Sensors in Air Quality and Health Studies in China**

Mei Zheng

*Mei Zheng<sup>1</sup>*

*1. College of Environmental Sciences and Engineering, Peking University, Beijing, China.*

Abstract: Air pollution in the Northern China has received great attention in recent years, primarily due to frequent haze in fall and winter. To understand the sources, formation mechanisms and health impacts, various techniques have been applied including speciation of fine particles at ground station, vertical profiles of pollutants, satellite retrieval of aerosol etc. In recent years, there is an increasing interest in studying air pollution and exposure using sensor technique in China. For example, high time- and spatial-resolution observation network using sensors has been installed in Beijing by the Beijing Environmental Monitoring Center and other 120 cities in China by Sailhero Environmental Technology, Inc. for long term monitoring purpose. The current observation network first serves its basic purpose, which helps to quickly identify hotspots and point sources of pollutants. Its application in exposure studies and source apportionment of pollutants has received increased attention in different communities. Sensor data have been applied for various purposes by different groups. For example, Shi et al. (2018) use data from the sensor network to determine representativeness of the ground station. The study shows that the representative area for a single station in the study period ranges from 0.25 to 16.25 km<sup>2</sup> but is less than 3 km<sup>2</sup> for most stations. Another study by Si et al. installs sensor in about 100 taxi in a city, and the system can uploads data of particulate matter and GPS location every three seconds, which can real-time map traffic-related pollution in a city. This study summarizes the major ongoing sensor-related programs in China in the following aspects: 1) comparing performance among sensors, 2) evaluating performance under different conditions such as relative humidity and temperature, 3) investigating sources and transport of pollutants, 4) examining spatial variation of pollutants, and 5) estimating exposure levels.

## 003.03A. Advances in Ambient Air Pollution Modeling 2

### 003.03.01. Land-Use Regression Models of Particulate Matter in Temuco, Chile Due to Residential Wood Burning

Carola Blazquez

*Daniel Cortez<sup>1</sup>, Carola A. Blazquez<sup>1</sup>, Maria Elisa Quinteros<sup>2</sup>, Siyao Lu<sup>3</sup>, Francisco Rubilar<sup>4</sup>, Juana Maria Delgado Saborit<sup>5</sup>, Pablo Ruiz-Rudolph<sup>2</sup>, Roy M. Harrison<sup>5</sup>*

- 5. School of Geography, Earth and Environmental Sciences, University of Birmingham, Birmingham, United Kingdom.*

**Abstract:** The spatial model development of particle distribution are necessary for studying the chronic health impacts of particulate air pollution due to residential wood- burning. The spatial variability of fine particulate (PM<sub>2.5</sub>) and ultrafine particles (UFP) due to wood-burning has not been studied in Chile. In this study, we used data from a mobile sampling campaign to develop a Land-Use Regression (LUR) model in the city of Temuco, Chile, which is a city heavily impacted by wood-burning. This campaign was performed for 28 days in the winter of 2016, in which PM<sub>2.5</sub> and UFP measurements of 1 s-intervals were recorded along four routes during nighttime when wood burning emissions are the highest. LUR models were developed to yield a map with spatial variability of PM<sub>2.5</sub> and UFP. Predictor variables were obtained from land use, transportation, demography, meteorology, and geography information in a GIS environment. A background normalization of PM<sub>2.5</sub> and UFP mean values at a 100 m resolution was applied to minimize day-to-day urban air quality variations. The results show that the LUR models were capable of explaining 0.43 and 0.31 of the variation in PM<sub>2.5</sub> and PUF, respectively. The number of households, length of local roads, and residential areas were positively correlated with PM<sub>2.5</sub> concentrations, whereas the average density of woodstoves, proximity to local roads, elevation, temperature, and precipitation were negatively correlated with PM<sub>2.5</sub>. The significant predictor variables positively associated with UFP concentrations were total population, major roads length, traffic intensity, and temperature, while the proximity to major roads and precipitation were negatively correlated with UFP. These results provide some insights for the development of a more sophisticated sampling campaign and LUR to be used to study chronic effects of particle exposure.

### **O03.03.02. Applying a Kinetic Multi-Layer Model of Surface and Bulk Chemistry in Epithelial Lung Lining Fluid to Estimate Spatial Variations in the Production of Reactive Oxygen Species in Response to PM2.5 Iron and Copper**

Scott Weichenthal

- 4. UC Irvine, Irvine, CA, United States.*

**Abstract:** Background: Certain metals may play an important role in the adverse health effects of fine particulate air pollution (PM2.5) but few models are available to predict spatial variations in these pollutants. Methods: We conducted large-scale air monitoring campaigns during summer 2016 and winter 2017 in Toronto, Canada to characterize spatial variations in iron (Fe) and copper (Cu) concentrations in PM2.5. Information on Fe and Cu concentrations at each site were paired with a kinetic multi-layer model of surface and bulk chemistry in the lung epithelial lining fluid to estimate the possible impact of these metals on the production of reactive oxygen species (ROS) in exposed populations. Land use data around each monitoring site were used to develop predictive models for Fe, Cu, and their estimated combined impact on ROS generation. Results: Spatial variations in Fe, Cu, and ROS greatly exceeded that of PM2.5 mass concentrations. In addition, Fe, Cu, and estimated ROS concentrations were 15, 18, and 9 times higher during summer compared to winter with little difference observed for PM2.5. In leave-one out cross validation procedures final multivariable models explained the majority of spatial variations in annual mean Fe ( $R^2= 0.68$ ), Cu ( $R^2=0.79$ ), and ROS ( $R^2= 0.65$ ). Conclusions: The combined use of PM2.5 metals data with a kinetic multi-layer model of surface and bulk chemistry in the human lung epithelial lining fluid may offer a novel means of estimating PM2.5 health impacts beyond simple mass concentrations.

### **003.03.03. Using Measurements of Nitrogen Oxides from a Fixed Sited and a Mobile Platform to Develop Spatially- and Temporally-Resolved Land Use Regression Models**

Laura Corlin

**Abstract:** Background: Land use regression models can have limited temporal representativeness or spatial resolution if mobile monitoring or fixed site data are used exclusively. Our objective was to build hourly spatial and temporal nitrogen oxides (NO<sub>x</sub>) models for 2003-2015 in Boston and Chelsea (MA, USA) by combining measurements from a mobile platform and a fixed reference site. Methods: NO<sub>x</sub> measurements were made with a chemiluminescence analyzer mounted in a mobile platform. Monitoring sessions (3-6 hours long) occurred on 49 days in Boston and 46 days in Chelsea between 2011 and 2015. Sessions occurred on all days of the week and in all seasons. We obtained hourly NO<sub>x</sub> measurements from a federal monitoring site in Boston. We calculated spatial factors, defined as the location-specific ratio between each 10-second mobile NO<sub>x</sub> value and the corresponding hourly mean fixed site NO<sub>x</sub> value. To model the spatial factors, we tested 43 covariates including transportation network and land use variables with data obtained from public sources. We prioritized covariates that most increased the adjusted-R<sup>2</sup> and made physical sense. We multiplied the modeled spatial factors by the fixed site hourly mean to estimate NO<sub>x</sub> at <200-m and 1-h resolution. Results: The models were stable with two cross validation methods. The most important predictors were distance from major roads, open space, and residential areas; presence of bus/train stops; and an interaction term for wind speed and being downwind of an airport. The models over-predicted at three validation sites, especially when concentrations were low and in places farther from major roads; however, the adjusted-R<sup>2</sup> values for hourly predictions were high (0.53-0.62) and the model captured seasonal and diurnal trends well for both study areas for 2003-2015. Conclusion: Our modeling approach is an efficient way to develop spatially and temporally resolved exposure estimates for use in concurrent and retrospective epidemiology studies.

### **003.03.04. Enhanced Geospatial Modelling of Traffic Related Air Pollution by Deconvoluting on Different Spatial Scales**

Greg Evans

Abstract: Vehicle emissions represent a major source of air pollution in many urban regions. Local and city-wide traffic, along with regional sources, can influence concentrations. Real-time pollutant measurement using mobile platforms allows assessment of concentrations across large cities but the temporally and spatially varying data thereby obtained can be difficult to interpret. Deconvolution of temporal signals may be an effective way to mine these data so as to isolate the contributions of sources with differing spatial scales. Mobile measurements were collected in Toronto, Canada and three cities in the Netherlands. The data were deconvoluted to isolate the contributions from local, neighbourhood and regional sources using a spline of minimums approach. A range of averaging times (10s to 3000s) was explored to represent these three spatial scales, with longer averaging times representing greater distances travelled by the mobile platforms. The three time-resolved signals, representing different spatial scales, were used to develop land-use regression models. Applying temporal signal deconvolution was found to enhance geospatial-based modeling of exposure in both countries by a small but significant amount. Compared to a conventional model, the deconvolution method increased predictive performance by 12% and 5% for ultrafine particles in Canada and the Netherlands respectively while for black carbon in Canada it only improved modelling by 1%. Further, in both countries the traffic related parameters identified for inclusion in the local scale geospatial models had smaller buffers sizes, while larger geospatial scale and meteorological parameters appeared in the models describing neighbourhood and regional scale contributions. The enhanced geospatial modelling observed for two very different locations indicates that temporal deconvolution is a promising way to interpret the complex temporally and spatially varying data obtained through mobile sampling.

### **O03.03.05. Incorporating Snow and Cloud Fractions in Random Forest to Estimate High Resolution PM2.5 Exposures in New York State**

Jianzhao Bi

*Jianzhao Bi<sup>1</sup>, Avani Wildani<sup>2</sup>, Yujie Wang<sup>3</sup>, Alexei Lyapustin<sup>3</sup>, Yang Liu<sup>1</sup>*

*2. Department of Math and Computer Science, Emory University, Atlanta, GA, United States.*

*3. Goddard Space Flight Center, National Aeronautics and Space Administration, Greenbelt, MD, United States.*

Abstract: Satellite aerosol optical depth (AOD) has been widely used to estimate the ground-level PM2.5 concentrations, but cloud/snow covers often lead to a large proportion of non-random missing AOD, causing difficulties in generating fully covered and unbiased PM2.5. Among the current approaches to address the data gap issue, few have considered the cloud-AOD relationship and none of them considered the snow-AOD relationship. This study aims to examine the influence of satellite-retrieved snow cover on AOD and PM2.5, and to generate accurate PM2.5 predictions in the areas with extensive snow cover. We chose New York State as our study domain since AOD missing rate here was ~ 90% and a large part of them was due to snow cover in winter. To estimate the missing AOD, a gap-filling model with cloud/snow fractions and other meteorological covariates was developed based on random forest algorithm. By applying this model, daily AOD dataset with 1 km resolution in 2015 was generated with complete spatial coverage. The "out-of-bag" R2 of the model averaged 0.93 with an interquartile range from 0.90 to 0.95. A random forest-based PM2.5 prediction model incorporating gap-filled AOD, land use, and meteorological terms was then developed to predict 1 km ground-level PM2.5 in 2015. Ten-fold cross-validation revealed good model performance with an R2 of 0.82. In the gap-filling model, snow fraction had a significantly higher importance in snow season of 2015. Models fitted with/without snow fraction also showed discernable PM2.5 pattern changes, further confirming the importance of this parameter. Compared to methods without explicitly considering cloud and snow cover, our PM2.5 prediction surfaces displayed more spatial details and reflected small-scale terrain-driven PM2.5 patterns. Our method can be generalized to the areas with extensive snow cover for producing reliable PM2.5 predictions with high resolution and complete coverage.

### **O03.03.06. Artificial Neural Networks to Mix Datasets from Particulate Matters and O3 in Medellín, Colombia**

Juan Piñeros Jiménez

*1. Universidad de Antioquia, Medellín, Antioquia, Colombia.*

**Abstract:** Mixing the datasets from different air quality monitoring stations to obtain an only dataset that represents a specific air contaminant concentration times series has been considered a difficult task not suited for linear models. The air contaminants datasets mixing is a relevant topic because helps to the data analysts like epidemiologist to obtain a time series from a location (city, town, neighbor) and relate it to another event or phenomena (morbidity and mortality events). In this work, we proposed the basic Artificial Neural Network (ANN) architecture has a merging method and we use it to obtain the daily average concentration for Particulate Matters (PM10, PM2.5), and O3 air contaminants from ten data sets to Medellín (Colombia) between 2008 and 2016. The ANN is a connectionist system inspired by the biological neural network, its goal is to learn the nonlinearities from the data and it is tolerant to modeling datasets with noise, outliers, and missing values. However, like other traditional techniques, the ANN can suffer overfitting. To control it, we used the weight decay strategy as regularization method and backpropagation with cross-validation as the learning algorithm. The algorithms were implemented in R programming language. We compared the air contaminants ANN mixed with the traditional mixing methods (the mean and median of the data sets). The merging performance of the ANN was better than the traditional method. In conclusion, the ANN merging can capture the dynamics and variability of the air contaminants datasets better than the traditional method. In addition, ANN are a suitable method to mix data values from a different air quality monitoring stations.

## 003.03B. Advancing Exposure Methodology through Suspect Screening and Non-Target Analysis

### 003.03.07. Suspect Screening Analysis to Identify Chemical Targets in Serum for Exposure Reconstruction

Barbara Wetmore

*Barbara A. Wetmore<sup>2</sup>, Katherine Phillips<sup>2</sup>, Kristin Favela<sup>1</sup>, Rebecca Church<sup>3</sup>, Jon Sobus<sup>2</sup>, Alice Yau<sup>1</sup>, Annette Rice<sup>3</sup>, Stavros Garantziotis<sup>3</sup>, John Wambaugh<sup>2</sup>*

1. Southwest Research Institute, San Antonio, TX, United States.
2. Office of Research and Development, US EPA, Research Triangle Park, NC, United States.
3. NIEHS, Research Triangle Park, NC, United States.

Abstract: Analysis of commercial chemicals in human biomonitoring efforts has been limited largely to those that are bioaccumulative with known or likely human health impacts. Exposure reconstruction using high throughput and other exposure models currently rely on these data alone for evaluation. The evolution of high resolution mass spectrometry affords the opportunity to expand the number of commercial chemicals for which such data are available. Suspect screening analysis (SSA) using two-dimensional gas chromatography-time of flight/mass spectrometry (GCxGC-TOF/MS) was performed on serum samples obtained from the National Institute of Environmental Health Sciences Clinical Research Unit. Samples were stratified based on sex (male vs. female). Tentative chemical identifications (IDs) were only assumed if a compound peak was identified in two of the three replicates, and if the spectrum for that peak had a high similarity to a spectrum in the NIST14 mass spectral library. Five hundred forty-six unique compounds were tentatively identified and assessed; 240 were detected in males, while double (480) were found in females. Two hundred seven compounds were unique to females while only 28 were unique to male serum. Sixty-nine of the tentatively identified chemicals were also detected in a pilot SSA that characterized chemical presence in consumer products (CP); 204 are present in US EPA's CPDat database, containing product composition and functional use data; and 5 are among the chemicals monitored in the National Health and Nutrition Examination Survey (NHANES) (e.g., naphthalene, cotinine, and 2,5-dichlorophenol). Ongoing work is focused on further identification efforts and strategies to facilitate semi-quantitative assessments. These preliminary findings provide support for the use of SSA in expanding the biomonitored chemical space for exposure reconstruction and model evaluation to inform chemical safety assessments. This abstract may not reflect U.S. EPA policy.

### **O03.03.08. Environmental Exposure Induced Metabolic Profiling Alterations in a Migration Panel between Los Angeles and Beijing**

Xinghua Qiu

*Xinghua Qiu<sup>1</sup>, Xinchun Lu<sup>1</sup>, Yan Lin<sup>2</sup>, Yifang Zhu<sup>2</sup>*

- 1. College of Environmental Sciences and Engineering, Peking University, Beijing, Beijing, China.*
- 2. University of California, Los Angeles, Los Angeles, CA, United States.*

**Abstract:** Migration provides individuals experiencing different environmental exposure episodes naturally, which offers a chance to attribute physiological response to certain exposure factors. To reveal the mechanism of health effect under environmental exposure, we designed a migration panel study between Los Angeles and Beijing, two cities with different exposure levels. Specifically, serum samples were collected from 27 summer school exchange students three times in total, one week before their departure (LA1), and at least four weeks respectively after their arrival to Beijing (BJ) and return to Los Angeles (LA2). The metabolic profiling was obtained through untargeted metabolomics approach with a high resolution TOF-MS. Combining with a series of statistical methods like Mann-Whitney test and Orthogonal partial least squares discriminant analysis, we screened prospective markers that changed significantly between LA and BJ. The significant decrease ( $p < 0.001$ ,  $FC > 1.2$ ) of indole and its precursor tryptophan in BJ reflected the induction of AhR and CYP by higher levels of pollutants. The decreased cortisol ( $p < 0.001$ ,  $FC > 1.5$ ) was potentially due to the accelerated consumption of CYP3A, supplying further evidence of enhanced CYP activity and related xenobiotics elimination in BJ. On the other hand, the increase of IL-8 and IL-10 from cytokine analysis suggested the oxidative stress during the process. A slightly higher level of uric acid ( $p < 0.01$ ,  $FC > 1.1$ ) along with its precursors implied the upregulation of antioxidation under the environmental exposure in BJ. Generally, this study illustrated that metabolomics offered an effective tool to assess the overall health impact under subchronic exposure.

### **O03.03.09. New Insights of Human Exposure to Consumer Product Chemicals from Comprehensive Chemical Profiles of Indoor Dust**

Hyeong-Moo Shin

*Hyeong-Moo Shin<sup>2</sup>, Christoph Moschet<sup>1</sup>, Thomas Young<sup>1</sup>, Deborah Bennett<sup>1</sup>*

*1. University of California, Davis, Davis, CA, United States.*

*2. University of Texas, Arlington, Arlington, TX, United States.*

**Abstract:** Background: For semivolatile organic compounds (SVOCs) with low vapor pressure, the levels in indoor dust are known to serve as an alternate marker of chemical exposure with common indoor sources. However, a complete picture of chemical fingerprint (i.e., identity and quantity of all chemicals present in dust) is missing because most previous studies focused on the analysis of known chemical classes in dust samples via a targeted analytical approach. Objective: This study presents concentrations of a broad spectrum of SVOCs in household dust measured via a comprehensive analytical workflow. Methods: We quantified SVOCs in dust samples collected from 38 California homes by applying a combination of target, suspect, and non-target screening approaches to liquid chromatography quadrupole time-of-flight mass spectrometry (LC-QTOF/MS) and gas chromatography (GC)-QTOF/MS. We used authentic standards to detect known compounds (targets), used existing databases or libraries, or software matching algorithms to detect expected compounds (suspects), and carefully examined the high-resolution mass spectra to identify previously unknown compounds (non-targets). Results: A total of 257 compounds were detected in at least one sample and 170 compounds were detected in more than 50% of the samples. Of the 257 compounds, 168 compounds were unambiguously confirmed and quantified by reference standards and 135 compounds were detected for the first time in U.S. household dust. Median concentrations ranged from 5 to ~100,000 ng/g of dust. We confirmed that 17 and 7 compounds newly detected in our dust are known to have endocrine disrupting and neurotoxic potential, respectively. Conclusions: We expect that a comprehensive investigation of chemicals present in dust from the present study will expand our knowledge of chemicals in household dust and will be the basis for further investigations in finding chemicals potentially associated with adverse health effects.

### **O03.03.10. Towards the Development of a Framework for Applying Non-Target Chemical Analysis Data within Exposure and Risk Assessment**

Todd Gouin

*Todd Gouin<sup>1</sup>, Jon Arnot<sup>2</sup>*

*1. TG Environmental Research, Sharnbrook, United Kingdom.*

*2. Arnot Research & Consulting, Toronto, ON, Canada.*

Abstract: There is an increasing trend towards multi-targeted and non-target analysis (NTA) screening methods to increase the number of analytes monitored in biomonitoring and environmental samples. While the opportunities from advances in chemical analytical capabilities have shown substantive development over recent years, application of information related to data reported from non-target analysis represents a challenge to the field of exposure modelling. For instance, there is no framework for interpreting and using data reported from studies involving non-target analysis to inform exposure and risk. The absence of guidance may consequently lead to difficulties in prioritizing risk assessment activities. In this study we examine the state of the science with respect to non-target analysis, and present a summary of the merits and limitations for exposure assessment and risk assessment. These preliminary observations are then used to propose an initial framework for the appropriate use of non-target analysis data within exposure assessment. The recommendations concludes with a number of suggestions regarding how these data can be better gathered and reported in order to strengthen their applications for chemical risk assessment, including emerging contaminants.

### **003.03.11. The Pregnancy Chemisome in Relation to Birth Outcomes and Consumer Product Use: Suspect Screening of Industrial Chemicals**

Aolin Wang

*Aolin Wang<sup>1</sup>, Jackie M. Schwartz<sup>2</sup>, Roy Gerona<sup>3</sup>, Thomas Lin<sup>3</sup>, Rachel Morello-Frosch<sup>4</sup>, Marina Sirota<sup>5</sup>, Tracey Woodruff<sup>2</sup>*

**Abstract:** Our study aims to characterize the chemical exposome among a diverse cohort of pregnant women and examine their relationship with birth outcomes, demographics, and consumer product use. We used liquid chromatography-quadrupole time-of-flight mass spectrometry to perform a suspect screen for 349 endocrine disrupting chemicals and 3000+ high-use industrial chemicals (based on Chemical Data Reporting 2016) in serum collected at delivery from 200 pregnant women in Northern California, and obtained both detection frequency and peak areas (relative concentration) for each suspect (matched by mass) compound. Analytical methods included multivariable linear/logistic regression, and an unsupervised machine learning technique association rule mining (ARM). We detected, on average, 60 suspects (SD=17, range: 21-100), the majority of which were matched to suspect environmental phenols or phthalate metabolites. Women with post-term (v.s. full term) babies have a lower number of suspects whereas those with low birth weight (LBW) babies have a higher number of suspects (b= -9 and 11 respectively). No demographic differences were observed in the number of suspects except that women with lower education appeared to have more suspect phthalate metabolites but small peak areas of suspect perfluorooctanesulfonic acid (PFOS). Peak areas of highly detected suspects were generally negatively associated with pre- and post-term birth and LBW, but positively associated with daily use of shampoo/conditioner and lotion (all FDR-adjusted  $p < 0.1$ ). ARM analysis suggested that lip balm, lotion, and deodorant are often used daily, and their use is associated with a higher number of suspects (support  $> 0.15$ , confidence  $> 0.8$ , and lift  $> 1$ ). Our results suggest associations of suspect chemicals in maternal serum with birth outcomes and consumer product use. Techniques such as the ARM could provide data-driven insights into potential patterns of chemical exposures and maternal characteristics.

### **O03.03.12. Ethical Dimensions of Advancing Exposure Methodology through Suspect Screening and Non-Target Analysis**

Colin Soskolne

Abstract: Given knowledge about the likelihood of harmful effects resulting from continued exposure, biomarkers of exposure provide evidence of exposure and thus assist in targeting Primary Prevention messaging in public health. Secondary Prevention involves screening to identify people who, given exposure, are experiencing patho-physiological changes that risk morbidity and premature mortality. The goal in Secondary Prevention is "early detection" as a means to interventions that could halt pathogenesis, preventing clinical manifestations and premature mortality. The focus in both Primary and Secondary Prevention in public health is on people, rather than on the more precise assessment of exposure. The latter, however, informs the former. On the exposure assessment side, the ability to develop tools to identify people who are likely unaware that they are exposed through the detection of biomarkers of exposure could add to prevention and teaching tools useful to advancing the public's health. Advances in technology make it possible for refined measurement tools for screening populations in ways unachievable in the past. What are the consequences of screening, both good and bad? The meta-ethical question is: Do we let technology drive our future, or can we shape it through ethical considerations? Simply put: Do we do what we do because we can or because we should? Practically, should we address exposure assessment without also considering health outcomes? Is it ethical not to translate results from health research into policy? Despite questions, the trajectory that humankind is on is one driven by technological advance. Ethical dimensions are often left to be considered after the fact, once the stable door has been opened. Being aware of this can enhance our role as citizen scientists. The ethical implications of exposure assessment tools will be drawn upon to engage delegates in discussion.

## O03.03C. Air Pollution, Obesity, and Metabolic Disease

### **O03.03.13. Particulate Air Pollution Exposure during Pregnancy and Mitochondrial-Associated Plasma Metabolites in Mothers at 48 Months Postpartum: A Pilot Study**

Megan Niedzwiecki

**Abstract:** Background Pregnancy and early postpartum life are periods of major metabolic change in women and may be critical windows of susceptibility for longer-term metabolic changes induced by inflammatory exposures, such as PM<sub>2.5</sub> (ambient particulate matter <2.5 μm in diameter). Hypothesis As mitochondria are sensitive to inflammation, we hypothesized that gestational/early postpartum PM<sub>2.5</sub> exposure would predict metabolomic profiles of small molecules in mitochondrial-associated pathways measured years after pregnancy. Methods In a pilot study, we randomly selected 50 mothers from the Programming Research on Obesity, Growth, Environment and Social Stress (PROGRESS) cohort based in Mexico City. We estimated PM<sub>2.5</sub> exposure using a satellite-based spatiotemporally-resolved prediction model. In maternal plasma collected at 48 months postpartum, we assessed 110 metabolites in mitochondrial pathways (TCA cycle, fatty acid β-oxidation, and branched chain amino acid catabolism) using Metabolon's Discovery HD4T platform. Results In robust regression models adjusted for age, secondhand smoke exposure, socioeconomic status, alcohol consumption, and parity, average PM<sub>2.5</sub> during the first year postpartum was associated with 17 metabolites (p<0.05). The majority were long chain fatty acids and polyunsaturated fatty acids, which were negatively associated with PM<sub>2.5</sub>. No associations were observed for these fatty acids with average PM<sub>2.5</sub> during pregnancy. Further, fewer metabolites overall were associated with PM<sub>2.5</sub> during pregnancy (two at p<0.05), suggesting results vary by time of exposure. Conclusion In this pilot study, we found that PM<sub>2.5</sub> exposure during the first year postpartum was associated with altered fatty acid metabolism in plasma from mothers at 48 months postpartum. The postpartum period may be a susceptibility window for PM<sub>2.5</sub> exposure with regard to metabolic dysregulation, particularly lipids. We plan to replicate these findings in the full sample and in independent cohorts.

### **003.03.14. A Pathway to Diabetes? Associations between Air Pollution Exposure and Biomarkers of Inflammation and Metabolism in Nondiabetic Persons.**

Sarah Lucht

*Sarah Lucht<sup>1</sup>, Frauke Hennig<sup>1</sup>, Susanne Moebus<sup>2</sup>, Noreen Pundt<sup>2</sup>, Uta Slomiany<sup>2</sup>, Dagmar Führer-Sake<sup>2</sup>, Christian Herder<sup>3</sup>, Karl-Heinz Jöckel<sup>2</sup>, Barbara Hoffmann<sup>1</sup>*

*3. Institute for Clinical Diabetology, German Diabetes Center, Leibniz Center for Diabetes Research at Heinrich-Heine University Düsseldorf, Düsseldorf, Germany.*

**Abstract:** Background: While prior studies have linked air pollution (AP) and diabetes, few studies have examined potential intermediate steps, such as inflammation and altered glucose metabolism, in metabolically healthy persons. Objective: To characterize associations between AP and biomarkers of inflammation and metabolism in nondiabetics. Methods: Biomarker measures (high-sensitivity C-reactive protein [hs-CRP], adiponectin, fibrinogen, interleukin-1 receptor antagonist [IL1-RA]) were collected at baseline (t<sub>0</sub>; 2000-2003) and first follow-up (t<sub>1</sub>; 2006-2008) exams from nondiabetic participants of the Heinz Nixdorf Recall (HNR) study. Residential mean exposure to PM<sub>10</sub>, PM<sub>2.5</sub>, NO<sub>2</sub>, and accumulation mode particle number concentration (PNAM) was calculated for time windows (1- to 365-day) prior to exam using a dispersion and chemistry transport model. We fitted covariate-adjusted linear mixed effects models and ran two-pollutant models for PNAM and NO<sub>2</sub>. Results: We analyzed 6,727 observations (n<sub>t0</sub>=3,626, n<sub>t1</sub>=3,101) from 4,052 participants of the HNR study (52% women; age 45-76 years at t<sub>0</sub>). Interquartile range (IQR) increases in 365-day mean exposure to PM<sub>10</sub>, PM<sub>2.5</sub>, and PNAM were associated with higher hs-CRP levels (e.g., PM<sub>2.5</sub>: 6.6% [95% CI: 2.8, 10.7] per IQR increase). Short-term exposure to all pollutants was positively associated with IL1-RA (e.g., 1-day PM<sub>10</sub>: 1.5% [0.6, 2.5] per IQR increase), with associations also seen for medium- and long-term exposures. Medium-term exposures (60- to 120-day) were negatively associated with adiponectin (e.g., 91-day PNAM: -2.2% [-3.3, -1.3] per IQR increase). No clear pattern was seen for fibrinogen. Associations for PNAM and NO<sub>2</sub> were robust to co-pollutant adjustment. Conclusion: In nondiabetics, we observed differing temporal patterns of association between AP and biomarkers of inflammation and metabolism, indicating that several exposure windows may be relevant for evaluating potential mediators of the link between AP and diabetes.

### **003.03.15. Ozone Exposure, Glucose Homeostasis and Insulin Resistance in the U.S.A.**

**Abstract:** Ozone Exposure, Glucose Homeostasis and Insulin Resistance in the USA Background: Epidemiological studies have suggested the associations between ambient air pollution levels and metabolic syndrome as well as diabetes. However, studies based on a national-wide sample are limited. Materials and Methods: In this study, we used the 1999-2002 restricted-access National Health and Nutrition Survey data (n=4,341 adults) to investigate the effects of air pollutants including fine particles (PM<sub>2.5</sub>) and ozone (O<sub>3</sub>) on glucose homeostasis and insulin resistance. We calculated daily average levels of air pollutants on each day in the preceding week and the preceding 1-month, 3-month, and annual averages of air pollutants at participants' geocoded home address. Linear regression models were applied for fast glucose, insulin, hemoglobin A1c (HbA1c), homeostasis model assessment of  $\beta$  cell function (HOMA- $\beta$ ), and insulin resistance (HOMA-IR). Logarithm transformation was applied to skewed variables. Results: We found that exposure to O<sub>3</sub> was significantly positively associated with fasting glucose level at lag days ( $\beta=1.18-1.69$  per 1 ppm change in O<sub>3</sub>,  $P < 0.05$ ), one month ( $\beta=1.97$ ,  $P = 0.02$ ), three months ( $\beta=2.29$ ,  $P = 0.03$ ) and one year window of exposure ( $\beta=3.47$ ,  $P = 0.01$ ). Additionally, O<sub>3</sub> exposure was significantly negatively associated with and HOMA- $\beta$  for all lag times. Monthly, 3-month and annual averages of O<sub>3</sub> were also positively associated with HbA1c. However, PM<sub>2.5</sub> was shown to have no strong relationship with these outcome measurements. Conclusions: Our study suggested that exposure to O<sub>3</sub> may have adverse effects on glucose homeostasis and  $\beta$ -cell function. The findings warrant further investigation.

### **003.03.16. Exposure to PM2.5 in Mexico City's Metropolitan Area and Its Association with Obesity**

5. HSPH, Boston, MA, United States.

**Abstract:** In Mexico City's Metropolitan Area (MCMA), home to over twenty million persons, air quality usually surpasses the standards for PM 2.5, and obesity is highly prevalent. Recent studies suggest inflammation as a possible link between PM 2.5 exposure and this disease, however epidemiologic research on this subject is scarce and has not been studied in a representative sample of the MCMA. We used data from the 2006 and 2012 Mexican Surveys of Health and Nutrition that have a multistage probabilistic sampling design, to estimate the association between PM 2.5 exposure and obesity in a representative sample of adults, adolescents 10-18 years old and children 2-9 years old from the MCMA. The yearly average PM 2.5 exposure was calculated for each participant's block address using satellite data, calibrated with the air quality network of ground air monitors. We used the sampling weights and clusters of the survey to estimate logistic regression models that were adjusted for age, sex, SES and tobacco (except in children); estimation was done with STATA svy program. Prevalence (% (95% C.I) of obesity was 29.9% (27.7-32.3) in 2006 and of 31.5% (28.5-34.6) in 2012 for adults; of 16.6% (13.5-20.3) in 2006 and of 15.9% (13.5-18.4) in 2012 for adolescents, and of 21.3% (17.7-25.5) in 2006 and of 18.8% (16.4-21.5) in 2012 for children. An increase of 10 µg/m<sup>3</sup> in the annual exposure to PM 2.5 was associated with obesity in adults for 2012, OR=2.73 (p=0.05, 95% C.I. 0.96-7.70) and in adolescents, for 2006 OR=3.40 (0.008; 1.39-8.26) and for 2012, OR=3.79 (0.01; 1.40-10.23). Results were inconclusive for children. Although obesity is a multifactorial disease, PM 2.5 might be an environmental risk factor contributing to this world-wide epidemic.

### **O03.03.17. The Impact of Indoor Fine Particles on Body Mass Index, Waist Circumference, and Triglyceride of Korean Housewives Cohort Study: Preliminary Results**

Shinhee Ye

*Shinhee Ye<sup>1</sup>, Yangho Kim<sup>3</sup>, Jongmin Oh<sup>1</sup>, Yumin Lee<sup>1</sup>, Wonho Yang<sup>2</sup>, Yun-Chul Hong<sup>4</sup>, Eun-Hee Ha<sup>1</sup>*

**Abstract:** Background: Few studies have evaluated the associations between indoor particulate matter (PM) and cardiovascular disease (CVD) risk factors in housewives who are exposed to large amount of indoor PM as they spend great deal of time doing house chores such as cooking and cleaning. Hence, we investigated the association between indoor PM and the CVD risk factors in housewives. Methods: We recruited 25 housewives (January to March 2018) in Ulsan, an industrial city, Republic of Korea. We measured indoor PM<sub>2.5</sub> (particulate matter <2.5 in diameter) concentrations at participant's house using weight method for 24hrs. Thereafter, participants were invited to hospital for a physical examination and collecting bio specimens (blood and urine) to analyze inflammatory markers, lipid profile, fasting insulin, and fasting glucose. Homeostatic Model Assessment for Insulin Resistance (HOMA-IR), body mass index (BMI), and metabolic syndrome (MS) were further defined. The association between PM<sub>2.5</sub> and CVD risk factors were evaluated using multiple linear regression or multiple logistic regression analysis. Results: The average indoor PM<sub>2.5</sub> concentration was 42.7 µg/m<sup>3</sup> (range: 13.2-143.2 g/m<sup>3</sup>). BMI (beta=0.06; 95% confidence interval (CI)=0.00-0.11), waist circumference (beta=0.15; CI=0.03-0.27), and triglyceride (beta=1.26; CI=0.19-2.33) were significantly associated with 1 g/m<sup>3</sup> increase of indoor PM<sub>2.5</sub>. The association between MS and PM<sub>2.5</sub> was marginally significant (odds ratio=1.09; CI=1.00-1.20). Blood pressure, C-reactive protein, total cholesterol, low density lipid cholesterol, fasting insulin, and HOMA-IR were increased with PM<sub>2.5</sub> concentrations, but not significant. Conclusions: In this preliminary study, several CVD risk factors are likely to be associated with an indoor PM<sub>2.5</sub> exposure in housewives. This study will be extended by recruiting about 300 housewives by 2019 to clarify this association.

**Abstract:** Background: Early-life exposure to air pollution has been suggested to influence childhood growth and Body Mass Index (BMI). DNA methylation changes might explain part of this effect. Yet, methylome-wide studies with population sizes under 1000 generally suffer from lack of power. Using a priori information to reduce data dimension is an option to face this challenge. Aim: To identify genes whose methylation level is possibly implied in air pollution effect on child BMI, with a 'Meet in the middle' approach, using a priori information from functional pathways. Methods: Among 1173 mother-infant pairs from Helix cohorts, exposures to 4 outdoor air pollutants were assessed during pregnancy and at age 7-9 years (total 16 exposures). Genome-wide DNA methylation levels in peripheral blood at 7-9 years was measured using HumanMethylation450 BeadChip, with quality control, batch and cell types adjustments. We a priori considered only 2276 CpGs from genes belonging to 16 growth or obesity-relevant pathways according to KEGG pathway database. Stabilized Elasticnet regression (ENet) was used to independently assess associations of DNA methylation with exposures and BMI. We identified exposures sharing associated CpG sites with BMI and assessed their direct association with BMI using ENet. Results: Exposures were associated with 358 CpG loci; 12 exposures were associated with CpGs also associated with BMI (total, 22 CpGs). One of these exposures, PM10 level the day before blood collection, was associated with BMI. This exposure was associated with 62 CpGs, 2 of which being also associated with BMI, on PIK3CA (thyroid hormone signaling pathway) and ELOVL3 genes (fatty acid elongation pathway). Conclusion: Our hypothesis-generating approach identified 358 CpGs from BMI-relevant pathways associated with air pollutants, including 22 related to child BMI. These CpGs provide hints as to which genes may be implied in mechanisms underlying air pollution effects on child growth.

Abstract: Historically, organophosphate and carbamate insecticides have been among the most commonly used insecticides, with both agricultural and residential uses. Previous studies have suggested associations with some of these chemicals and non-Hodgkin lymphoma (NHL); however, many have been limited in their ability to evaluate associations with subtypes. We evaluated the use of eleven organophosphate and two carbamate insecticides in association with NHL in the North American Pooled Project, which includes data from case-control studies in the United States and Canada (1,690 cases/5,131 controls). We used unconditional logistic regression adjusting for potential confounders, including use of other insecticides, to estimate odds ratios (OR) and 95% confidence intervals (95% CI) for associations between these chemicals and NHL overall, and follicular (FL), diffuse large B-cell (DLBCL), small lymphocytic lymphoma (SLL) and other subtypes. Ever use of the insecticide malathion was associated with increased risk of NHL overall in 172 exposed cases (OR=1.43; 95% CI: 1.14-1.81) compared to never users. The risk was highest in those who reported using malathion >6 years (n=103 cases) (OR=1.57; 95% CI: 1.18-2.10). In addition, there were statistically significant associations for FL (OR=1.58; 95% CI: 1.11-2.27) and DLBCL (OR=1.61; 95% CI: 1.16-2.22) subtypes. There were no apparent associations with SLL or other subtypes. The carbamate insecticide carbaryl was associated with a non-significantly increased risk of NHL overall for ever use (OR=1.17; 95% CI: 0.84-1.64) among 75 exposed cases, and for >6 years of use (OR=1.24; 95% CI: 0.78-1.99). There was a statistically significant increased risk of SLL, but not other subtypes, with ever use of this chemical (OR=2.12; 95% CI: 1.01-4.42). These results support previous studies suggesting an association between these commonly used insecticides and NHL overall, and provide new information on associations with NHL subtypes.

**Abstract:** Several studies have suggested arsenic may target important tumor-suppressor genes and disrupt cell cycle control and influence bladder cancer risk. In a large, population-based case-control study we evaluated whether there was heterogeneity in the arsenic-bladder cancer risk relationship by tumor expression of p16 and Rb. Tumor tissue from bladder cancer cases was assembled as tissue microarrays and examined for expression. Cutoff values used to define negative/positive staining were based on the distribution of the percentage of positive cells in cases. Data on cumulative arsenic from drinking water were used to evaluate the relationship between arsenic and bladder cancer by immunophenotype (p16-/p16+, Rb-/Rb+), in 424 cases and 1287 controls, using polytomous logistic regression. Our results show that the association between increasing cumulative arsenic and bladder cancer risk was only apparent among patients with p16+ or Rb+ tumors. We observed a strong monotonic association between risk and increasing cumulative arsenic intake (Quartile2-4 vs. Quartile1, OR<sub>p16+</sub> =1.36, 1.47, 1.85, p-trend=0.004 and OR<sub>Rb+</sub> =1.51, 1.56, 1.94, p-trend=0.007). No association between cumulative arsenic and risk among patients with p16- or Rb- bladder tumors was apparent (p-heterogeneity by subtype=0.0325 for p16 and 0.0551 for Rb). This heterogeneity was not evident by stage or grade. Our data suggest a low frequency of homozygous deletion of CDKN2A (the gene that encodes p16), as well as inactivating mutations of RB1 in arsenic-induced bladder cancer, pointing to an alternate mechanism. Increased p16 expression may be indicative of hypermethylation of CDKN2A, an intensively studied mechanisms for arsenic-induced carcinogenesis. Our data provide additional evidence linking arsenic exposure and bladder cancer risk and point to alterations of the cell cycle as the relevant pathway, although the precise mechanisms need further evaluation in additional experimental and human studies.

Abstract: Acute lymphoblastic leukemia (ALL) is the most common form of childhood leukemia. Metabolomics analysis of archived dried blood spots (DBS) collected at birth provides a snapshot of early life exposures that can provide insights into the causes and underlying prenatal biology of ALL. We received single 4.7-mm DBS punches (equivalent to ~8  $\mu$ L whole blood) collected between 1985 and 2005 for over 300 ALL cases and their matched controls as part of the California Childhood Leukemia Study. Matching was performed on date of birth and gender and roughly matched on ethnicity. DBS were extracted with acetonitrile and analyzed with an Agilent 1290 UHPLC system connected to a 6550 QTOF HRMS (Santa Clara, US) in ESI (-) mode. Analysis was performed on subjects stratified by age at diagnosis as a means of distinguishing between potentially different ALL phenotypes (early: 1-5 years; late: 6-14 years). In order to minimize the number of false positives, associations between metabolite features and ALL were determined with an ensemble of statistical methods, namely, linear regression p-values, bootstrapped regularized logistic regression (LASSO), and random forest. There was no overlap in features selected for associations with early diagnosis (9 features) and late diagnosis (24 features) of ALL. Annotated metabolites were primarily fatty acid and glycerophospholipids. Several of the selected metabolites were associated with the time to ALL diagnosis, suggesting that they reflect effects of disease progression rather than causal exposures. Interestingly, several metabolites selected in the late diagnosis group were highly associated with breastfeeding practice, a known risk factor of ALL. Since DBS are collected within 48 hours of birth, they include nutrients from one or more infant feedings. These results suggest that lipids associated with neonatal nutrition may be involved with initiation of ALL in early life and should be a focus of future targeted research.

### **003.03.22. Hematologic Perturbations among Pesticide Applicators Recently Exposed to Permethrin in the Agricultural Health Study**

Joe Shearer

*Joe Shearer<sup>1</sup>, Laura Beane Freeman<sup>1</sup>, Danping Liu<sup>1</sup>, Gabriella Andreotti<sup>1</sup>, Jennifer Hamilton<sup>2</sup>, Julie Happel<sup>3</sup>, Charles Lynch<sup>2</sup>, Michael Alavanja<sup>1</sup>, Hofmann Jonathan<sup>1</sup>*

**Abstract:** In the Agricultural Health Study (AHS), a large prospective cohort of pesticide applicators, exposure to the pyrethroid insecticide permethrin is associated with an increased risk of multiple myeloma (MM), a hematologic malignancy with an unfavorable prognosis. To gain insight into the biological mechanisms underlying this association, we assessed potential hematotoxic effects of permethrin, in a longitudinal study of 35 permethrin-exposed male pesticide applicators in the AHS. Serial blood samples were collected from each participant in the off-season, the day after permethrin use, and approximately 3 weeks after use. At each time point, we performed a complete blood count with white blood cell differential and measured lymphocyte subsets. We used linear mixed models to assess the relationship between permethrin exposure and cell counts, controlling for season, age, BMI, recent cold/infection ( $\leq 7$  days), and use of other pesticides ( $\leq 30$  days). We observed a statistically significant increase in the geometric mean of immature granulocytes (31%, 95% CI=6%, 63%) on the day after permethrin use relative to off-season levels, but not 3 weeks after use. Statistically significant ( $P < 0.05$ ) alterations in several red blood cell parameters were also observed on the day after permethrin use, including decreased red blood cell count, hemoglobin, and hematocrit and increased mean corpuscular volume and red blood cell distribution width-SD. Red blood cell count, hemoglobin, and hematocrit remained significantly decreased 3 weeks after permethrin use. Increased immature granulocytes are indicative of an inflammatory response and enhanced bone marrow activity, and sustained decreases in red blood cell parameters may be a result of increased oxidative stress. Our results suggest inflammatory and hematologic effects of permethrin exposure, and identify targeted cell populations for future mechanistic studies to elucidate the relationship between permethrin use and MM risk.

**Abstract:** Background: A relationship has been hypothesized between moderate solar ultraviolet radiation (UVR) exposure and breast cancer. This hypothesis centers on the anti-proliferative and apoptotic properties of vitamin D, as well as increases in nocturnal melatonin concentrations which have been shown to slow cellular proliferation. To date, the literature on the effects of exposure to UVR and breast cancer risk have not been systematically reviewed and synthesized. Furthermore, the effects of sun avoidance (low amounts of time spent in the sun) in different exposure windows (adolescence vs. a period relevant to diagnosis) have not been compared. Methods: We conducted a systematic review and meta-analysis to investigate the association between sun avoidance (defined as less than an hour of sun per day) and the risk of developing breast cancer. Associations were estimated using random effects models. Heterogeneity was investigated through subgroup analyses and I<sup>2</sup> statistics. Results: Seven studies were included in this review with the majority (n=5) being conducted in Canada or the US. We observed an increased risk of breast cancer for individuals obtaining less than an hour of sun exposure per day during summer months compared to individuals that obtained greater than an hour (pooled relative risk (RR) = 1.15; 95% CI: 1.09-1.20). Heterogeneity among this body of literature was minimal (I<sup>2</sup> = 2.7%) Among studies that measured sun exposure over different life periods, sun avoidance during adolescence appeared to confer a qualitatively greater risk of breast cancer than that closer to diagnosis (pooled RR = 1.18; 95% CI: 1.05-1.30 vs. 1.05; 95% CI: 0.88-1.25). Conclusion: This is the first meta-analysis to estimate the risk of developing breast cancer associated with sun avoidance. The results of this study suggest that obtaining less than one hour of sun per day during summer months, especially in adolescence, could increase the risk of developing breast cancer.

### **O03.03.24. Different Coffee Products and Breast Cancer Risk among Hong Kong Chinese Women**

Ming Yi Lee

**Abstract:** Background: Coffee contains caffeine and polyphenols that were reported to be able to low breast cancer risk, but the evidence from epidemiological studies remains inconsistent. Coffee products (i.e. instant, brewed) contain various levels of sugars and food additives, and thus their effects on breast cancer may vary and research on this area is lacking. This study aims to investigate the associations between coffee products and breast cancer risk among Hong Kong Chinese women. Methods: We conducted a hospital-based case-control study in three public hospitals, 1835 Chinese women (912 controls and 923 incident breast cancer cases) aged 24 to 84 years were consecutively recruited and interviewed using a standardized questionnaire including detailed information on coffee drinking. Results: There were no associations between overall coffee drinking and breast cancer risk. Interestingly, the association between instant coffee and breast cancer risk was contradicting to that of consuming coffee from restaurant. Compare to non-habitual coffee drinkers, women who drank  $\geq 1$  cup(s) of instant coffee per day (adjusted odds ratio (OR)=1.47, 95% confidence interval(CI)=1.02-2.11) was significantly associated with an increased risk of breast cancer after adjusting their age, body mass index, family history of breast cancer, educational level and shift work experiences. On the other hand, women who drank  $\geq 1$  cup(s) of coffee from restaurant/chain coffee per day (adjusted OR=0.34, 95% CI= 0.12-0.94) was negatively associated with breast cancer risk. Conclusion: Coffee products under different processing methods may be a novel risk factor for breast cancer and further research is warranted.

## 003.03E. Chemical Exposures in Vulnerable Populations

### **003.03.25. Influence of Genetic Variance on Occupational Exposure to 1,6-Hexamethylene Diisocyanate (HDI) and Its Trimer HDI Isocyanurate**

Laura Taylor

**Abstract:** Polyurethane spray-painting can result in significant occupational exposure to 1,6-hexamethylene diisocyanate (HDI) monomer and its trimer, HDI isocyanurate. Inter-individual genetic differences have been linked with adverse health effects and asthma risk in isocyanate-exposed workers. However, little is known about inter-individual differences in response to HDI isocyanurate exposure compared to the HDI monomer. We are investigating the similarities and differences in exposure-dose responses and the genetic variants that modify or predict relationships between toxicokinetics and biomarker levels in exposed workers. Inhalation and skin exposure to HDI monomer and HDI isocyanurate were measured in 33 spray-painters along with the respective urine and blood biomarkers of 1,6-hexamethylene diamine (HDA) and trisaminohexyl isocyanurate (TAHI). Genome-wide microarrays (Affymetrix 6.0) were used to genotype the workers' single nucleotide polymorphisms (SNPs) and to conduct a genome-wide association study (GWAS). Using exposure values as covariates and a false discovery rate <0.20 for significance, GWAS showed that one SNP was associated with TAHI levels in urine, six SNPs were associated with HDA in plasma, and twelve SNPs were associated with HDA levels in urine. No SNP associations reached significance for TAHI levels in plasma. The SNPs were tested in linear mixed models (LMM) and bioinformatics data of the genes proximal to the top ten most significant SNPs for each compound were assessed for biological plausibility. Bioinformatics for HDI monomer associated SNPs included predicted interactions involving signal transduction and the immune function. Bioinformatics for HDI isocyanurate predicted interactions for cell signaling, structure, and adhesion. We demonstrate that genetic variance impacts the biomarker levels in workers exposed to HDI monomer and HDI isocyanurate, and that HDA and TAHI levels can be used to refine exposure prediction models for both compounds.

### **003.03.26. Association of Heavy Metals with Measures of Pulmonary Function in Youth: Findings from the 2011-2012 National Health and Nutrition Examination Survey (NHANES)**

Jessica Madrigal

*Jessica Madrigal<sup>1</sup>, Victoria Persky<sup>1</sup>, Andrea Pappalardo<sup>2</sup>, Maria Argos<sup>1</sup>*

*2. Department of Pediatrics, University of Illinois at Chicago, Chicago, IL, United States.*

**Abstract:** Exposure to cadmium, cobalt, lead, and manganese occurs through inhalation of industrial pollution and tobacco smoke, or ingestion of contaminated food and water. High exposure to these metals has been associated with decreased pulmonary function in adults. Little is known about these associations in children exposed at low levels in the United States (U.S.). We evaluated the cross-sectional associations of blood and urinary concentrations of cadmium, cobalt, lead, and manganese in relation to pulmonary function [forced expiratory volume in one second (FEV1; mL), forced vital capacity (FVC; mL), FEV1 to FVC ratio (FEV1:FVC), and midexhalation forced expiratory flow rate (FEF 25-75%; mL/second) in a sample of 1,234 U.S. children and adolescents aged 6 to 17 years from the 2011-2012 cycle of the National Health and Nutrition Examination Survey (NHANES). Survey-weighted linear regression models were performed to estimate beta coefficients and their 95% confidence intervals (CIs), adjusting for age, race, sex, height, family income, respiratory medication use, exposure to tobacco smoke, and urinary creatinine concentration (urinary exposure models only). Blood manganese concentration was inversely associated with FVC ( $\beta$  for highest versus lowest quartile=-97.1, 95% CI=-230.6, 36.4;  $p$  for trend=0.03). The associations of blood manganese with both FEV1 and FVC differed by age ( $p$  for interaction=0.04 and 0.03, respectively), indicating an inverse trend that was strongest among youth aged 11-17. Urinary manganese was inversely associated with FEV1:FVC and FEF 25-75% ( $p=0.05$  and  $0.02$ , respectively). Urinary lead was inversely associated with FEF 25-75% ( $p=0.01$ ). Our findings suggest that environmental manganese and lead exposure may adversely impact the pulmonary function of children. This association highlights the need to prioritize environmental health protection, evaluate these associations prospectively, and further investigate underlying mechanisms.

### **O03.03.27. A Bayesian Benchmark Dose Analysis for Manganese in Drinking Water and IQ in Children Based on Pooled Data from Two Studies in Canada**

Maryse Bouchard

*Savroop Kullar<sup>1</sup>, Kan Shao<sup>2</sup>, Maryse Bouchard<sup>1</sup>*

- 1. Environmental and Occupational Health, Université de Montreal, Montreal, QC, Canada.*
- 2. Department of Environmental Health, Indiana University School of Public Health, Bloomington, IN, United States.*

**Abstract:** Background: Manganese (Mn) is an essential nutrient but can be neurotoxic at high exposure levels. We carried out two cross-sectional studies on the relation between water Mn levels and IQ in children. Although this metal is commonly found in drinking water, few jurisdictions have adopted a health-based guideline to limit its concentration. The Bayesian Benchmark Dose Analysis System (BBMD) can be used to estimate the level of exposure associated with a predefined health risk in a probabilistic framework. Objective: To pool samples from two studies and use BBMD to estimate the water Mn level associated with predefined levels of cognitive impairment in children, i.e. reduction of 1 and 2 IQ points. Methods: Data from two studies were pooled resulting in a sample of 630 children (ages 6-13 years). We sampled each participant's home tap water and measured Mn concentration. The performance IQ (PIQ) score was used as the primary outcome. The BBMD is based on Bayesian statistics featuring Markov Chain Monte Carlo algorithms for model fitting, parameter and quantity of interest estimation. The weight-averaged median estimate and the lower bound of the credible interval (BMDL) of multiple commonly used dose-response models are reported. Results: The concentration of Mn in drinking water associated with a decrease of 1 PIQ point was 120 µg/L (BMDL, 69 µg/L); for a decrease of 2 PIQ points, this concentration was 243 µg/L (BMDL, 140 µg/L). Different associations for water Mn and PIQ were found between sexes, so stratified analyses were also conducted. The Mn concentration associated with a decrease of 1 and 2 PIQ points in boys was 174 and 354 µg/L (BMDL, 68 and 138 µg/L) and 72 and 94 µg/L (BMDL, 9 and 19 µg/L) for girls. Conclusion: A maximum acceptable concentration for manganese in drinking water should be set to protect children, the most vulnerable population for Mn neurotoxicity. The present risk analysis can guide the decision-makers regulating water quality.

### **003.03.28. Effects of an Educational Intervention on Organophosphate Pesticides in the Risk Perception and Chlorpyrifos, Diazinon and Parathion Metabolites Levels in Chilean Rural Schoolchildren**

María Teresa Muñoz-Quezada

*María Teresa Muñoz-Quezada<sup>1</sup>, Boris A. Lucero<sup>1</sup>, Veronica Iglesias<sup>2</sup>, Maria P. Munoz<sup>2</sup>, Liliana Zuñiga<sup>3</sup>, Carlos Concha<sup>4</sup>, Juan Pablo Gutiérrez<sup>5</sup>*

- 4. Secretaría Ministerial de Salud de la Región del Maule, Talca, Chile.*
- 5. Doctorate in Applied Mathematical Modeling, Faculty of Basic Sciences., Universidad Católica del Maule, Talca, Chile.*

**Abstract:** Background: Organophosphate (OP) pesticides, if not applied with due precautions, can be hazardous to health. There is evidence in the Maule region that rural school children are exposed to OP. Objective: To evaluate the impact that an educational intervention has on the exposure to OP and risk perception of two school communities in the Maule Region. Method: A cross-community randomized trial was applied in schoolchildren from two rural schools in the Maule Region in 2016-2017. The sample size was 48 (24 for each school). The average concentration of OP metabolites chlorpyrifos (CPM), diazinon (Oxy2), malathion (MAM) and paration (PAR) in repeated measurements of urine samples of schoolchildren during a week for two days at the beginning of October and two days was evaluated at the end of November of each year. The risk perception of schoolchildren and their parents before and after the intervention was measured simultaneously. Samples were analyzed at the CDC laboratory (USA). Results: Preliminary results for 2016 are showed here. MAM were below the limit of detection (LOD); while OP of measure 1 were CPM = 1.2g / L and measure 2 CPM = 1.3g / L; measure 1 Oxy2 = 0.09 g / L and measure 2 Oxy2 = 0.4g / L; measure 1 PAR = 0.9 g / L and measure 2 PAR = 1.2g / L. The PAR is banned in Chile since 2000. In multiple linear regression models, CPM metabolites in the urine were associated with fruit at school and application of OP pesticides at home. PAR and CPM were correlated in urine in both measurements ( $p = 0.0004$ ) suggesting that both are applied combined. The educational intervention allowed a greater awareness and knowledge of the risks of OP in schoolchildren and their parents. Conclusion: It is necessary to strengthen the intervention of school communities, involve government entities and agricultural companies, considering that are applying dangerous pesticides without preventing the population, providing guidelines to reduce community exposure.

### **003.03.29. The Nasal Methylome as Biomarker of PM2.5 Exposure in Children**

**Abstract:** Background: The nasal methylome is easily accessible and in direct contact with the environment, potentially serving as an epigenetic biomarker. Methods: We conducted nasal epigenome-wide association analyses of exposure to ambient fine particulate matter (PM2.5) within the Project Viva cohort among 503 children (mean age 12.9 y). We used residential addresses to estimate daily ambient PM2.5 levels with 1km resolution during the day of sample collection, 7-days and 1-year prior moving average (MA). Trained personnel collected nasal swabs from the anterior nares and DNA methylation (DNAm) was measured using the Illumina MethylationEPIC BeadChip. We tested 701,812 high quality autosomal CpGs conducting CpG-by-CpG and regional DNAm analyses. We adjusted for maternal education, smokers living in the household, child sex, race/ethnicity, BMI z-score, age, season at sample collection, heterogeneity driven by cell-type and accounted for multiple comparisons. Additionally, we evaluated the ability to predict PM2.5 exposure by DNAm marks using LASSO. Results: Mean (SD) PM2.5 levels during the day of sample collection, 1-week, and 1-year prior were 7.44 (3.04), 7.43 (2.02) and 7.76 (0.55)  $\mu\text{g}/\text{m}^3$ , respectively. Adjusted analyses identified 6,220 CpGs associated with 1-year PM2.5 levels (FDR<0.05), including 80 CpGs passing Bonferroni correction ( $P < 7.1 \times 10^{-8}$ ), and 30 differentially methylated regions (FDR<0.05) having 10 or more CpGs. Results included genes previously associated with PM2.5 in an EWAS of adult blood (ANKHD1, ANKRD11). Using 80% of the data for training (N=402), we identified 17 CpGs that moderately predicted 1-year PM2.5 levels ( $r=0.44$ ) in the remaining validation set (N=101). Conclusion: We observed widespread nasal DNAm variability associated with ambient PM2.5 levels 1-year prior to sample collection but no associations with short term levels. The nasal methylome may serve as a sensitive epigenetic biomarker of long-term PM2.5 exposure.

### 003.03.30. Infants' Exposure to Organophosphate Esters (OPES)

Kate Hoffman

*Kate Hoffman<sup>1</sup>, Amelia Lorenzo<sup>1</sup>, Joyce Grandee<sup>2</sup>, Liz Schmidt<sup>2</sup>, Stephanie Smith<sup>2</sup>, Lynn Harrington<sup>2</sup>, Jennifer Michael<sup>2</sup>, Brian Eichner<sup>3</sup>, Heather Stapleton<sup>1</sup>*

- 1. Nicholas School of the Environment, Duke University, Durham, NC, United States.*
- 2. Duke Human Vaccine Institute, Duke University, Durham, NC, United States.*
- 3. Duke Children's Primary Care, Durham, NC, United States.*

**Abstract:** Organophosphate esters (OPES) are frequently used as flame retardants and plasticizers in consumer products, including those specifically designed for use by infants (e.g. carseats and play mats). Though data suggest nearly everyone is exposed to OPES, exposure levels among infants and the factors associated with higher levels of exposure are largely unknown. As a part of the ongoing CHildren's Immune ResPonse (CHIRP) Study, urine samples were collected from central North Carolina children at 2 and 12 months of age (89 samples from 61 individual children). Using mass spectrometry methods we measured 6 urinary OPE metabolites in samples. Bis(1,3-dichloropropyl) phosphate (BDCIPP) and diphenyl phosphate (DPHP) were detected in 100% of sample and other metabolites were also detected frequently [ $>80$  of samples contained isopropyl-phenyl phenyl phosphate (ip-PPP), bis(1-chloro-2-propyl) 1-hydroxy-2-propyl phosphate (BCIPHIPP), bis(2-chloro-isopropyl) phosphate (BCIPP), and tert butyl-phenyl phenyl phosphate (tb-PPP)]. Median metabolite concentrations were generally substantially higher than those reported for older children or adults. Age was inversely associated with chlorinated metabolites. For example, BCIPHIPP levels were 3.7 times higher at 2 months of age than at 12 months of age ( $10\beta=4.7$ : 95% Confidence Interval: 3.1, 6.2). Breastfeeding was associated with significantly higher BCIPHIPP levels ( $10\beta=1.7$ : 95% CI: 1.2, 2.5) and suggestively higher levels of several other metabolites, indicating that breastmilk may be a source of exposure to OPES. Demographic characteristics were associated with urinary metabolites (e.g. maternal education and race) as was the season of sample collection. Ownership and use of various baby products was also associated with OPE metabolites, but patterns varied by age and metabolite. Cumulatively, results indicate that infants have higher levels of exposure to OPES, raising concerns given infants' sensitivity to environmental insults.

**O03.03.31. Nicotine and Flavor Emissions from Electronic Cigarettes**

Jonathan Thornburg

*Jonathan Thornburg<sup>1</sup>, Seung-Hyun Cho<sup>1</sup>, Michelle McCombs<sup>1</sup>, Nalyn Siripanchignon<sup>1</sup>*

*1. RTI International, Research Triangle Park, NC, United States.*

Abstract: Use of electronic nicotine delivery systems (ENDS), such as electronic cigarettes (e-cigarettes), is increasing in the United States and globally. Despite the growing use of e-cigarettes, little is known about the physical and chemical properties of e-cigarette emissions inhaled by the user, and what device, topography, user preferences influence their exposure. The objective was to produce a physiologically relevant e-cigarette aerosol by mimicking the temperature and humidity found in a user's respiratory system. This approach produced an "inhaled" aerosol with more representative physical and chemical properties than sampling directly from the e-cigarette. The output from the system corresponded to the expected aerosol size distribution and chemical composition in the user's lungs. Our experiments characterized aerosol size distribution, nicotine and flavor yield (micrograms per puff) and gas-particle partitioning as a function of liquid type, device settings, and user topography. The aerosol size distribution produced by all liquids were different. We found that elevated humidity and residence time inside the simulated lung activated the growth of condensation nuclei. The resulting aerosol size distribution varied from 100 nm to 220 nm in count median diameter. The aerosol chemical composition changed under humid conditions because the humectants promoted absorption of nicotine and flavorings into the liquid droplets. Device power and puff volume jointly affected nicotine, menthol, vanillin, and benzyl alcohol yield. A statistically significant power function related the device settings and topography to the yield. These initial data provide evidence that exposure to electronic cigarette emissions can be significant. The size distribution and chemical composition of the inhaled emissions vary as with device power and puff volume. This variability could alter the acute and chronic health of electronic cigarette users as their proficiency with using the device increases.

### 003.03.32. Metal Exposure from E-Cigarette Users in Maryland

Angela Aherrera

Angela Aherrera<sup>1</sup>, Rui Chen<sup>1</sup>, Atul Aravindakshan<sup>1</sup>, Ana Rule<sup>1</sup>, Ana Navas-Acien<sup>2</sup>

1. *Environmental Health and Environmental*, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States.

2. *Environmental Health*, Columbia Mailman School of Public Health, New York, NY, United States.

**Abstract:** Background As more is known about the components of electronic cigarettes (e-cigarettes), it is important to characterize metal exposure from use. Nickel (Ni) and chromium (Cr) are frequent components of e-cigarette heating coils and have been found in e-liquid and aerosol. We compared Ni and Cr biomarker concentrations among Maryland e-cigarette users to that of non-e-cigarette users/non-smokers, and also assessed the association of e-cigarette use patterns with metal biomarker concentrations. Methods We recruited 50 e-cigarette users and 50 non-e-cigarette users from March to October 2017. Data were collected on health status, e-cigarette use patterns, device characteristics, sociodemographic factors. Urine, saliva, and exhaled breath condensate (EBC) samples were collected. Metal concentrations were measured using ICP-MS. Results The median Cr concentrations for non-users and e-cigarette users were 0.92 and 1.77 µg/l in urine, 0.62 and 0.73 µg/l in saliva, and both 0.14 µg/l in EBC, respectively; median Ni concentrations were 0.68 and 1.11 µg/l in urine, 0.27 and 0.55 µg/l in saliva, and both 0.13 µg/l in EBC. Compared to non-users, e-cigarette users had significantly higher levels of Ni concentration in urine (GMR 3.99, 95% CI: 1.95-8.19,  $p < 0.001$ ). Increased urine Ni concentrations were observed among users who vaped at a higher voltage (3.65-4.20 volts) and used a higher nicotine concentration (12-24 mg/ml). Saliva Cr concentrations were increased with more e-liquid consumed per week (35 to 60 ml). Both Ni and Cr saliva concentrations were increased among users that changed their coils more frequently (>2/month). Conclusion E-cigarette users had significantly higher levels of Cr in urine than non-users. Ni in urine and Cr in saliva were positively associated with higher e-cigarette use and voltage. Increased metal concentrations in saliva associated with more frequent coil change provide an indication that instructions and best practice of using coils is warranted.

### **003.03.33. Temporal Stability of Urinary Cadmium in Samples Collected Several Years Apart in a Population of Older Persons**

Jaymie Meliker

*Jaymie Meliker<sup>1</sup>, Caterina Vacchi-Suzzi<sup>1</sup>, James Harrington<sup>2</sup>, Keith E. Levine<sup>2</sup>, Lily Lui<sup>3</sup>, Douglas Bauer<sup>3</sup>, Eric Orwoll<sup>4</sup>, Deborah Kado<sup>5</sup>*

- 3. UCSF, San Francisco, CA, United States.*
- 4. Oregon Health & Science University, Portland, OR, United States.*
- 5. UCSD, San Diego, CA, United States.*

**Abstract:** Objectives: There is growing evidence that urine cadmium is a temporally stable biomarker indicative of long-term cadmium exposure; however questions remain with regard to generalizability to older persons, the impact of changes in smoking behavior, and the degree of temporal stability when repeat sample collection spans years instead of weeks or months. Methods: Using pre-existing samples from male (Osteoporotic Fractures in Men (MrOS-US)) and female elderly cohorts (Study of Osteoporotic Fractures (SOF)), we analyzed two morning spot urine samples each from 39 males and 18 females. We stratified by smoking history and then randomly selected males, who had a mean age of 74, and females who presented with a mean age of 76. For the males, samples were collected approximately 6 years apart, and 4 years apart for the females. Intra-class correlations were computed to assess temporal stability, and adjusted for age and BMI. Results: The median (standard deviation) creatinine-adjusted urinary cadmium levels (0.39 ( $\pm$  0.26), 0.89 ( $\pm$  0.51)  $\mu$ g/g for MrOS and SOF, respectively) were similar to levels expected for these age/sex groups in the US according to the National Health and Nutrition Examination Survey. The intra-class correlation was high (ICC=0.85) and similar between cohorts (MrOS: ICC=0.74; SOF: ICC=0.81). ICCs were similarly high for current smokers (ICC=0.89) and never smokers (ICC=0.82) but slightly smaller among those who stopped smoking between waves of sample collection (ICC=0.68) or among former smokers (ICC=0.64). Conclusions: We report good-to-excellent reproducibility of urine cadmium using morning spot urine samples collected 4-6 years apart from male and female older persons, but slightly smaller correlations among those with a history of smoking who are no longer smoking.

### **O03.03.34. Cadmium Exposure, Active Smoking and DNA Methylation Profiles in Human Blood DNA Samples from the Strong Heart Study**

Arce Domingo Relloso

*Arce Domingo Relloso<sup>1</sup>, Karin Haack<sup>2</sup>, Shelley A. Cole<sup>2</sup>, Christine Ladd-Acosta<sup>3</sup>, Wan-Yee Tang<sup>3</sup>, Daniele Fallin<sup>3</sup>, Ana Navas-Acien<sup>1</sup>, Maria Tellez-Plaza<sup>4</sup>*

*3. Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States.*

*4. Biomedical Research Institute INCLIVA, Valencia, Spain.*

**Abstract:** BACKGROUND Experimental studies suggest that exposure to cadmium may alter DNA methylation (DNAm). In addition, DNAm status at several genomic sites has been associated with smoking in methylome-wide epidemiologic studies. Cadmium in cigarettes has been proposed as a causative agent for multiple health outcomes. The objective of this study was to investigate the mediator role of cadmium in the association between smoking and genomic DNAm profiles in 2325 Strong Heart Study participants. METHODS DNAm was measured in 860079 loci using the Illumina Infinium Human MethylationEPIC platform. Data were preprocessed, including correction for batch effect and cell heterogeneity. Cadmium concentrations in urine were determined by Inductively Coupled Plasma Mass Spectrometry, corrected by creatinine and log-transformed. Associations for active smoking on DNAm were estimated using linear regression models adjusted by age, body mass index, sex, with and without cadmium levels when required. We used the "difference of coefficients" method and the mediation R package to estimate the relative contribution of cadmium to smoking-associated DNAm. RESULTS 38.4 % of the participants were active smokers. Median urinary cadmium was 0.97 µg/g. At a Bonferroni significance level of 5.91e-08, we replicated well-known associations of active smoking with DNAm. Among the 1858 significant sites, the top 5 mediated effects (% of association attributed to cadmium) were observed for NFIB (cg03253449, 31.33 %), IFIH1 (cg19965693, 28.9 %), CDC42BPB (cg02003183, 27.71 %), HSD17B12 (cg14262884, 27.19 %) and AHRR (cg00731338, 21.37 %). CONCLUSIONS The association of active smoking and DNA methylation in well-established smoking associated DNAm sites was partially attributed to cadmium. Our results suggest that cadmium might be a partial mediator of the association between smoking and health outcomes through epigenetic mechanisms. These results need to be replicated in an independent study population.

### **O03.03.35. Pattern of Prenatal Secondhand Smoke Exposure among Rural Women in Main Tobacco Production Region, China**

Xia Xiao

*Xia Xiao<sup>1</sup>, Xiaoxiao Song<sup>1</sup>, Jie Wu<sup>1</sup>, Qinghua Xu<sup>1</sup>, Siwei Yang<sup>1</sup>, Yan Li<sup>1</sup>, Yan Zhang<sup>1</sup>*

*1. School of Public Health, Kunming Medical University, Kunming, Yunnan, China.*

**Abstract:** Background: Prenatal secondhand smoke (SHS) exposure is the most modifiable risk factor associated with adverse birth outcomes. However, few researches were interested in finding the heterogeneity change tendency throughout pregnancy. The objectives of this study were to explore the heterogeneity by classifying subgroups based on the trajectories of urine cotinine (UC) throughout pregnancy in main tobacco production region, so as to provide individual intervention. Methods: This study used a prospective prenatal cohort consisting of 385 pregnant women who were UC validated as passive smoking at first (T1), second (T2) and third trimester (T3) time points. Urine cotinine were analyzed by high performance liquid chromatography-tandem mass spectrometry. The limit of detection for cotinine was 0.08ng/mL. Latent Class Growth Curve Modeling (LCGCM) was used to classify pregnant women into the unobserved subgroup (latent classes) with similar trajectories of UC. Results: The three-class patterns were determined prefer based on the information criteria. The general trends of UC in three patterns were upward with different trajectories from T1. The first class was steep increase at T2 and followed by sharp decrease at T3 (n=7, 1.8%); the second class was flat increase throughout pregnancy (n=98, 24.8%); the third class was moderately rising during pregnancy (n=290, 73.4%). The minority group and residence in tobacco production areas were positively associated with the UC increase trend. Conclusions: Patterns of prenatal SHS exposure among rural women generally go up with different trajectories during pregnancy. The lifestyle of minority and living environment of tobacco production may increase UC level. LCGCM may assist to better understanding the pattern of UC change over time. Identification of three subgroups and their distinctive patterns of change have the potential help for individual intervention.

### **O03.03.36. Polycyclic Aromatic Compounds Identified in Thirdhand Smoke Contaminated House Dust**

Penelope Quintana

Abstract: Thirdhand smoke (THS) is the residue of tobacco smoke that remains in house dust and on surfaces, and can be re-emitted into air and further react in the indoor environment to create additional compounds. THS-contaminated house dust poses a special risk to children due to their hand-to-mouth behaviors, as well as their vulnerable stage of development. Chemicals already characterized in THS-contaminated house dust include nicotine, tobacco-specific nitrosamines, and polycyclic aromatic hydrocarbons (PAHs). Here we report on the concentrations of a suite of non-traditionally measured polycyclic aromatic compounds (PACs), including oxygenated-PAHs and methyl-PAHs, which may be more toxic than parent PAHs. House dust samples were collected using the HVS3 cyclone vacuum from homes of smokers (n=30) and nonsmokers (n=9) in San Diego, CA, USA, and characterized for a variety of PACs by GCxGC/ToF-MS. Multiple PACs were elevated in dust samples from smokers' as compared to nonsmokers' homes. Of particular note was the detection of 1,2-naphthoquinone (1,2NQ), which was the most highly abundant oxy-PAH, and was elevated in smokers' homes relative to nonsmokers' (median 7822 ng/m<sup>2</sup> vs. 4111 ng/m<sup>2</sup>), though this difference was not significant. 1,2NQ levels were significantly correlated with nicotine measured in the same samples ( $\rho = 0.0374$ ,  $p=0.027$ ), suggesting that this compound may be associated with THS. 1,2 NQ is directly mutagenic and has not been reported before in house dust to our knowledge, though it has been reported in tobacco smoke, PM2.5 air pollution and diesel exhaust. Results indicate that measurement of traditional 16 EPA PAHs may underestimate toxic compounds in house dust, and that thirdhand smoke in house dust may be a source of elevated levels of certain toxic PACs. The compound 1,2 NQ and other PACs in house dust may pose a risk to children and policies should be strengthened to prevent THS exposure in homes.

### **O03.03.37. Measurement Error in Epidemiological Studies of Allergenic Pollen Due to Heterogeneity in Flowering Phenology**

Daniel Katz

*Daniel S. Katz<sup>1</sup>, Stuart Batterman<sup>1</sup>*

*1. Environmental Health Sciences, University of Michigan, Ann Arbor, MI, United States.*

Abstract: Most epidemiological studies of allergenic pollen compare daily measurements from a pollen monitoring station with health outcomes from across a city or region, implicitly assuming that pollen is released at the same time across the study areas. However, cities contain temperature gradients that could cause trees in some neighborhoods to flower substantially earlier or later, potentially resulting in differences in airborne pollen concentrations between the regional pollen monitoring station and neighborhoods within the study area. The resulting pollen exposure measurement errors could be large and may result in substantial bias. In this study, epidemiological studies of allergenic pollen are reviewed and temperature gradients within their study areas are quantified. In addition, the effects of an intra-urban temperature gradient on flowering time and airborne pollen concentrations were measured in an observational study conducted on oak and mulberry trees in Detroit, USA. In the epidemiological studies, 50% of study areas were not within 1° C of the pollen measurement location. In the field study, a difference of 1° C resulted in 4 and 10 days difference in flowering time for oak and mulberry. Airborne pollen concentrations were correlated with estimated flowering time for oak ( $R^2 = 0.25$ ,  $p < 0.001$ ) and mulberry ( $R^2 = 0.68$ ,  $p < 0.001$ ) but were only weakly correlated with pollen concentrations measured at the pollen monitoring station for oak ( $R^2 = 0.07$ ,  $p > 0.05$ ) and mulberry ( $R^2 = 0.04$ ,  $p > 0.05$ ). These results provide evidence of intra-municipal heterogeneity in tree flowering and differences in airborne pollen concentrations between neighborhoods within a metropolitan area and the regional pollen monitoring station. This cautions against using measurements from a single pollen monitoring station as a proxy for pollen exposures if the study area contains climatic variability.

### **003.03.38. Human Responses to Biophilic Indoor Environment**

Jie Yin

**Abstract:** Biophilic design, which incorporates natural elements into the built environment, has received increasing attention in both design and health fields. Epidemiological and experimental studies have provided sufficient evidence that contact with outdoor nature has positive impacts on human health and wellbeing. However, the potential for similar health benefits in indoor biophilic environments remains unclear. We designed a randomized crossover study to examine the physiological and cognitive responses to biophilic indoor environments by using virtual reality (VR) and wearable bio-monitoring sensors. In this study, 28 participants spent time in an indoor environment featuring biophilic design elements and one without, with the order of the visit randomized. In each visit, they experienced the same environment for 5-minutes in reality and virtually by using VR. The indoor biophilic environment was associated with a decrease in participants's blood pressure. The overall differential effects for participants experiencing an indoor environment with biophilic elements versus none was 8.56 (95%CI: 5.60-11.52) mmHg lower systolic and 3.57 (95%CI: 0.36-6.78) mmHg lower diastolic blood pressure. In addition, their skin conductance decreased by 0.18 (95%CI: -0.004-0.36)  $\mu$ S and short-term memory improved by 14% (95%CI: 5.3%-23.2%). Moreover, our findings indicate that participants had similar physiological and cognitive benefits in the virtual environment and actual environment. The results indicate that biophilic environment may be beneficial in reduce stress in indoor settings. Additionally, the parity in results in virtual and real environments provides evidence that using VR can be an effective tool to simulate visual exposures when access to the real environment is not feasible.

### **O03.03.39. Built Environment, Microbiota and Asthma at Age 3: Longitudinal Follow-Up in a Canadian Birth Cohort**

Hind Sbihi

*Hind Sbihi<sup>1</sup>, Charisse Petersen<sup>1</sup>, Rozlyn C. Boutin<sup>1</sup>, Chelsea J. Cutler<sup>1</sup>, Malcolm R. Sears<sup>5</sup>, Padmaja Subbarao<sup>3</sup>, Theo J. Moraes<sup>3</sup>, Piush Mandhane<sup>4</sup>, Meghan Azad<sup>2</sup>, Allan Becker<sup>2</sup>, B. B. Finlay<sup>1</sup>, Stuart E. Turvey<sup>1</sup>*

**Abstract:** Background The Canadian Healthy Infant Longitudinal Development (CHILD) birth cohort was designed to define factors related to the development of asthma. We examined modifiable environmental exposures and gut microbiota with respect to asthma incidence. Methods Stool samples collected at 3 and 12 months from an asthma-enriched CHILD subset (n=999) were profiled with 16S rRNA sequencing. Mothers' built environment was assessed at their residential addresses with a satellite measure of greenness (NDVI) and land use regression models to derive nitrogen dioxide (NO<sub>2</sub>) individual estimates of traffic-related air pollution (TRAP). Data were collected on intrinsic risk factors, including parental asthma status, mode of delivery, parity, socio-economic factors, and antibiotic use. We examined the association of gut microbiota composition with environmental factors and their impact on asthma at age 3yrs. Results Children with asthma at 3 years (n=312) had higher exposure to NO<sub>2</sub> (mean (SD): 16.1 (7.2) ppb) and lower exposure to greenness (NDVI mean (SD): 0.25 (0.08)) compared to those without asthma (NO<sub>2</sub>: (14.7 (6.8) ppb); NDVI: 0.26 (0.08)). Children with asthma were more likely to have atopic primiparous mothers who were prescribed antibiotics during pregnancy. While microbiome alpha diversity increased between 3 months and 1 year, maternal atopy (p=0.06) and prenatal TRAP exposure (p=0.05) were negatively associated with this trend. Infants diagnosed with asthma by 3yrs had different microbiota composition at 3 months (p=0.002), including reduced *Oscillospira* colonization (FDR p<0.05). Prenatal TRAP exposure also accompanied shifts in beta-diversity at 3 months (p=0.002) and was negatively correlated with *Oscillospira* abundance (spearman r=-.13; FDR p<0.01). Conclusions Increased alpha diversity and *Oscillospira* abundance-known health protective features of the microbiota-were negatively associated with TRAP which is a key modifiable environmental risk factor.

### **O03.03.40. Spatial and Temporal Associations between Allergic Rhinitis, Asthma and the Environment in Toronto, Canada**

Jordan Brubacher

*Jordan Brubacher<sup>1</sup>, Bimal Chhetri<sup>1</sup>, Kelly Sabaliauskas<sup>2</sup>, Kate Bassil<sup>2</sup>, Stephanie Gower<sup>2</sup>, Jeffrey C. Kwong<sup>3</sup>, Frances Coates<sup>4</sup>, Tim K. Takaro<sup>1</sup>*

Abstract: Exposure to various plant pollen and fungal spores contribute to asthma and allergic rhinitis (AR) exacerbations and may cause these chronic illnesses to develop. These organisms interact with the weather, which influences production, timing and dispersal of their airborne glycol-proteins. We describe associations between weather, pollen, spores, air pollution, AR and asthma in Toronto, Canada in order to gain a better understanding of possible future trends under a changing climate. We also describe spatial associations between land cover and these health outcomes to better understand how urban form may be related to respiratory health. Exposure estimates were derived from aeroallergen and air pollution monitors, and health outcomes were characterized using the number of Toronto residents who accessed health services for AR and asthma between 2004 and 2014. A separate analysis investigated associations between aeroallergens and weather using various time lags to account for the complex relationships between weather and biota. Geographic weighted regression was used to investigate the spatial relationships between these diseases and tree canopy cover, distance to Lake Ontario and building height, and spatial scan tests were used to identify clusters. Significant associations ( $p < 0.05$ ) were observed between air pollutants, multiple taxa of plant pollen, and both allergies and asthma. There was 70.5 and 61.2 percent deviance explained in the AR and asthma spatial models, respectively. Areas with higher AR and asthma were associated with less tree cover, greater distance from the lake and shorter buildings. Spatial scan tests identified hot spots that remained constant from season to season. Social deprivation will be added as a covariate (analysis underway). These findings can inform opportunities for illness prevention as weather patterns and ecologies shift with climate change.

**Abstract:** Background: Longitudinal evidence of beneficial associations between exposure to greenness and pregnancy outcomes are limited. Our objective was to evaluate these associations among 78,671 livebirths in Tel Aviv, Israel. Methods: longitudinal exposure to mean greenness during pregnancy and trimesters were calculated using satellite-based Normalised Difference Vegetation Index (NDVI) from MODIS 8-days interval data. In addition, exposure to mean NDVI from high-resolution satellite (RapidEye) and percent of tree cover (Vegetation Continuous Fields (VCF)) at various radii (100m, 300m and 500m), were evaluated in a cross-sectional approach. Generalized linear models were used to evaluate the associations between greenness and pregnancy outcomes in crude and adjust models. Results: In models adjusted for individual and neighborhood-level markers of socioeconomic status (SES), highest tertile of exposure to mean NDVI during pregnancy was associated with a statistically significant increase in birth weight (3rd/1st tertile increased mean birth weight in 13.2 g 95% CI: 5.0, 21.4) and decreased odds of very preterm delivery (PTD) (3rd/1st tertile OR: 0.80, 95 %CI: 0.64, 1.00). The strongest associations for birth weight observed during the first trimester and for very PTD during the second trimester. Associations for the cross-sectional approach were similar and in addition decreased odds of small for gestational age (SGA) and low birth weight (non-linear associations) were observed. Associations with NDVI were stronger than the associations with tree cover. Associations were consistent for further adjustment and stronger for low SES. Conclusion: Consistent beneficial associations using different greenness measures and approaches are reported. Further studies should use the longitudinal approach because it allows us to understand when exposure during pregnancy to green environment is the most beneficial for pregnancy outcomes.

### **O03.03.42. Association between Green Space and Pregnancy Outcomes: A Case-Study in Temuco, Chile. Preliminary Results**

**Abstract:** A rapidly growing body of research has recently shown beneficial health effect of urban green environment and natural spaces. Latin America is the world's most urbanized region, with largest social and economic inequities, facing important challenges in city design, and availability of green spaces. Here, we examine the association between residential surrounding greenness and pregnancy outcomes in a Temuco, a mid-size city in Chile. To our knowledge, this is the first study of this kind in Latin America. A retrospective cohort is being conformed using pregnancy records from the main public Hospital in Temuco during 2009 - 2016, including sociodemographic and medical inputs. Pregnancy outcomes included: preeclampsia and gestational diabetes, for the mother; and preterm birth, low birth weight, term birth weight, small for gestational age, birth weight, gestational age and head circumference, for the newborn. Home address was georeferenced using the Google map geocoding API. Greenness was estimated for each address by using the NDVI from satellite data in buffers of 100, 300 and 500m. Separate logistic multivariate models were fitted for each outcome adjusted for potential confounders. Effects were estimated for changes in one interquartile range (IQR) in surrounding greenness. From expected 16,000 total records, preliminary results are shown for the first 9800 (2009-2013). Overall, analyses show decreased risks of gestational diabetes (OR 0.97 IC95% 0.85 - 1.10 for 300m buffer), preterm birth (OR 0.94 IC95% 0.78 - 1.15 for 300m buffer), low birth weight (OR 0.94 IC95% 0.77 - 1.16 for 300m buffer), and small for gestational age (OR 0.99 IC95% 0.86 - 1.13 for 300m buffer) associated with an IQR increase in NDVI. Preliminary findings point to beneficial impact of surrounding greenness in fetal growth, although not reaching statistical significance. Analysis will be repeated once data entry is complete (end of April).

## 003.03H. Health Outcomes and Biomarkers Associated with Household Cooking and Biomass Burning 1

### **003.03.43. Biomonitoring Exposure to Household Air Pollution in Children: Results from a Cook Stove Intervention Study in Kenya**

Zheng Li

Zheng Li<sup>1</sup>, Kanta Sircar<sup>3</sup>, Andreas Sjobin<sup>3</sup>, Antonia Calafat<sup>3</sup>, Bryan E. Christensen<sup>2</sup>, Fuyuen Yip<sup>3</sup>

1. Division of Toxicology and Human Health Sciences, U.S. Agency for Toxic Substances and Disease Registry, Atlanta, GA, United States.

3. National Center for Environmental Health, U.S. Centers for Disease Control and Prevention, Atlanta, GA, United States.

**Abstract:** Background: Indoor biomass stoves are common in developing countries. Such stoves release harmful pollutants such as polycyclic aromatic hydrocarbons (PAHs) and lead to household air pollution (HAP). HAP disproportionately affects women and children because they spend more time at home near stoves. In 2012, we conducted a cross-over study in two Kenya villages to investigate HAP exposure in households with traditional three-stone stoves and six different improved stoves. We report HAP exposure among children living in the households by biomonitoring PAH biomarkers in urine. Method: Forty-five households using only traditional stoves participated in the study and tested up to six new stoves (two-week usage/stove, one-week break). We collected urine samples from the youngest children (4 years or younger, 25 boys and 19 girls) in each household at baseline (n=44) and at the end of each period after using an improved stove (n=29-34). Up to two urine samples were collected on two consecutive days from each child, resulting in 81 urine samples at baseline and 51-61 samples at each period. We measured 9 hydroxy PAHs (OH-PAHs)-metabolites of naphthalene, fluorene, phenanthrene and pyrene-in 417 urine samples. Results: Median urinary OH-PAH concentrations in this study were 5-22 times higher than that of the U.S. children (6-11 years) from NHANES 2011/12. For example, median 1-hydroxypyrene was 2.0 pg/L (fresh weight), which was 16 times higher than that of the U.S. children (0.127 pg/L). Among the improved stoves, using the Ecochula (an electric fan-assisted gasifier) and Prakti (a double-pot rocket with chimney) showed the largest reduction of median urinary OH-PAH levels in children (averaging 28% and 21% reduction, respectively) compared to using traditional 3-stone stoves. Conclusion: Several stoves showed a moderate reduction in urinary PAH biomarker levels among children. Even with the improved stoves, HAP exposure in this study is high compared to the U.S. children.

### **O03.03.44. Effect of Biomass Fuel Exposure on Pregnancy Outcomes in Rural Bangladesh**

Khandaker Islam

*Khandaker Islam<sup>2</sup>, Tasnia I. Sharna<sup>1</sup>*

*1. MCHD, iccdr,b, Chittagong, Bangladesh.*

*2. Preventive Medicine, University of Southern California, Los Angeles, CA, United States.*

Abstract: Low birth weight is a major cause of infant morbidity and mortality in low-income countries like Bangladesh. Emerging data suggest that exposure to biomass fuel (BMF) smoke, common during cooking with BMF, might affect birth weight. Here we investigated whether exposure to BMF smoke is associated with pregnancy outcomes in rural Bangladesh. As part of the Cook Stove Study of Bangladesh (CSSB) we recruited 903 pregnant women within 6-18 weeks of pregnancy. Detailed sociodemographic, health, diet, and pertinent exposure data (type of fuel used, duration of cooking, kitchen type and others) were collected by trained interviewers. Anthropometric measurements of the newborns (N=797) were done by field personnel within 24-72 hours of delivery. This analysis was restricted to newborns born within 37-42 weeks of gestation (N=736). Participants who used coal, wood, leaves, agricultural residues, or cow dung were categorized as solid fuel users (n=602). We fitted a multivariable linear regression model to assess the effect of exposures of interest on birth weight, length and head circumference after adjusting for gestational age, and maternal age, BMI, diabetes status and hypertension. The mean ( $\pm$ SD) birthweight of the newborns was 2736 gm ( $\pm$ 370gm). Almost 82% of the women used solid fuel for cooking and spent on average 3.32hrs ( $\pm$ 1.8hrs) for cooking. We observed a statistically significant interaction for the use of solid fuel and duration of cooking on birth weight ( $p=0.03$ ) and marginally significant interaction on birth length ( $p=0.1$ ). Based on hour model coefficients, 3.32 hours of cooking with solid fuel can lead to a 145gm reduction in birthweight, compared to a woman who does not cook or spend time in the kitchen during cooking. Exposure of pregnant women to solid fuel smoke during cooking has a detrimental effect on birth weight of the newborn.

### **003.03.45. Acute Respiratory Symptoms and Risk Factors in Pregnant Women Cooking with Biomass Fuels in Rural Ghana**

- 6. Lamont-Doherty Earth Observatory, Columbia University, Palisades, NY, United States.*

**Abstract:** **BACKGROUND:** Eighty-three percent of the population in Ghana relies on biomass fuels for cooking and heating needs. Household air pollution (HAP) emitted from the incomplete combustion of these fuels has been associated with adverse health effects including respiratory effects in women that can lead to chronic obstructive pulmonary disease (COPD), a major contributor to global HAP-related mortality. **OBJECTIVE:** This study assessed the prevalence of respiratory symptoms, as well as associations between respiratory symptoms and HAP exposure, as measured using continuous personal carbon monoxide (CO), in nonsmoking pregnant women in rural Ghana. **METHODS:** We analyzed acute respiratory health symptoms and CO exposures upon enrollment in a subset (n=840) of the population of pregnant women cooking with biomass fuels and enrolled in the GRAPH randomized clinical control trial. Personal CO was measured using Lascar real-time monitors. Associations between CO concentrations as well as other sources of pollution exposures and respiratory health symptoms were estimated using logistic regression models. **CONCLUSION:** There was a positive association between CO exposure and a composite respiratory symptom score of current cough (lasting > 5days), wheeze or dyspnea (OR: 1.2, 95% CI: 1.02, 1.45). CO was also positively associated with wheeze (OR: 1.3, 95% CI: 1.00, 1.63). Adjusted multivariate models showed significant associations between environmental (second-hand) tobacco smoke (ETS) and the composite outcome (OR: 2.1, 95% CI: 2.0, 3.5), and individual outcomes of cough>5 days (OR: 3.1, 95% CI: 1.31, 7.23), wheeze (OR: 2.7, 95% CI: 1.44, 5.15) and dyspnea (OR: 2.2, 95% CI: 1.19, 3.97), although fewer women were exposed to ETS. Results suggest that exposures to HAP and ETS increase the risk of adverse respiratory symptoms among pregnant women using biomass fuels for cooking in rural Ghana.

### 003.03.46. Examining the Relationship between Household Air Pollution and Infant Nasal Carriage

Daniel Carrion

*Daniel Carrion<sup>1</sup>, Kenneth Asayah<sup>2</sup>, Ellen Boamah<sup>2</sup>, Mohammed Mujtaba<sup>2</sup>, Alison Lee<sup>3</sup>, Kaali Seyram<sup>2</sup>, Darby Jack<sup>1</sup>, Kwaku Poku Asante<sup>2</sup>*

- 2. Kintampo Health Research Centre, Kintampo, Ghana.*
- 3. Icahn School of Medicine at Mount Sinai, New York, NY, United States.*

**Abstract:** Background/Aim: Pneumonia, the leading cause of childhood mortality worldwide, is associated with household air pollution (HAP) exposure. Mechanisms between HAP and pneumonia are poorly understood, but the Randomized Exposure Study of Pollution Indoors and Respiratory Effects trial in Guatemala identified severe pneumonia as more likely of bacterial, rather than viral, etiology. Our research seeks to confirm relationships between HAP and infant bacterial carriage, specifically among those diagnosed with pneumonia. Methods: Data were collected through the Ghana Randomized Air Pollution Study (GRAPHS), which recruited mother-infant pairs until the child's first birthday. Improved biomass, LPG, or 3-stone (baseline) cookstoves were randomly assigned to participants. The current analysis is restricted to LPG and 3-stone arms. Carbon monoxide (CO) exposures were measured for each infant and fieldworkers conducted surveillance for pneumonia. Cases were sent for treatment and nasopharyngeal swabs. Age and sex-matched controls were swabbed. Swabs were analysed with MassTag PCR for common infections. Statistical analyses included group-wise comparisons of microbial pathogens by study arm. At study completion, the association between CO-levels and specific microbes will be analysed. Results: Preliminary analysis demonstrates participants in the 3-stone arm have higher microbial levels than the LPG intervention arm ( $p < 0.0001$ ) ( $N=198$ ). This difference appears driven by bacterial ( $p < 0.0001$ ) rather than viral levels (non-significant) among 3-stone participants. Bacterial-level differences are consistent when stratifying by cases ( $p < 0.0001$ ) and controls ( $p = 0.0049$ ). Forthcoming analysis will assess the effects on specific microbe species. Conclusions: Findings could strengthen knowledge of pneumonia etiology. Childhood pneumonia is a grave public health concern and these data could inform public health efforts, including HAP interventions or vaccination programs.

### **003.03.47. Exposure Profiles of Cooking Behaviors, Socioeconomic Status, and Housing Characteristics Are Strongly Associated with Childhood Asthma in Kampala, Uganda**

Eric Coker

*Eric S. Coker<sup>1</sup>, Brenda Eskenazi<sup>1</sup>, Samuel Kizito<sup>2</sup>, Achilles Katamba<sup>2</sup>, Luke Davis<sup>3</sup>*

*1. School of Public Health, University of California, Berkeley, Entebbe, Wakiso Distric, Uganda.*

*2. Makerere University, Kampala, Uganda.*

*3. School of Public Health, Yale University, New Haven, CT, United States.*

**Abstract:** Despite the known health risks of household air pollution (HAP), less is known about how cooking behaviors and housing characteristics cluster to determine health risks. We performed a case-control study of children under 15 years of age presenting with cough at health centers in Kampala, Uganda (n=607) from January-March, 2018. Among homes who cook with a polluting fuel (charcoal, wood, kerosene), we applied Bayesian Profile Regression and identified exposure profiles of cooking-related behaviors, socioeconomic status (SES), and housing characteristics associated with asthma (current wheeze and at least one other asthma symptom). Compared to a referent exposure profile, characterized by cooking outdoors and low SES, the odds of asthma were significantly higher (OR 9.7, 95%CI 4.9-21.3) in an exposure profile characterized by high proportions who cook in a room unattached to the home or in a kitchen in the home, a room with no windows, with children indoors during cooking, who use a polluting fuel for lighting, and with low SES and low crowding. Odds of asthma were significantly higher (OR 3.37, 95%CI 2.10-5.65) in an exposure profile characterized by high proportions who cook in the main sleeping area that has windows, with children indoors during cooking, who use a polluting fuel for lighting, and with low SES and high crowding. The odds of asthma (OR 1.58, 95%CI 0.96-2.63) were similar to the referent in an exposure profile characterized by high proportions who cook in a room unattached to the home or in a kitchen in the home, a room with windows, with children outdoors during cooking, who use electricity for lighting, and with high SES and low crowding. Our analysis suggests that cooking behaviors, SES, and housing characteristics exhibit clustering patterns that are associated with higher odds of asthma. Design of cookstove interventions to reduce HAP and associated asthma should consider interactions among a combination of social, behavioral, and housing factors.

### **O03.03.48. Inflammatory Effects of Short-Term Exposure to Smoke Emissions from Biomass Fuels**

Binaya Kc

*Binaya Kc<sup>1</sup>, Parth Sarathi Mahapatra<sup>2</sup>, Amanda Henry<sup>1</sup>, Siva Praveen Puppala<sup>2</sup>, Ian Sayers<sup>1</sup>, Bim P. Shrestha<sup>3</sup>, Ian P. Hall<sup>1</sup>*

- 2. International Centre for Integrated Mountain Development (ICIMOD), Kathmandu, Nepal.*
- 3. Kathmandu University, Dhulikhel, Nepal.*

**Abstract:** Short-term exposure to household air pollution (HAP) has been linked with increased respiratory symptoms including cough and breathlessness. More prolonged exposure to particulate matter and other toxic chemicals from biomass combustion worsens health outcomes and may lead to premature death. Airway inflammation following exposure to inhaled pollutants is likely to be a key step in this process. The present study aims to evaluate the inflammatory effects of short-term exposure to biomass smoke extract on human bronchial epithelial cell and ex vivo human lung tissue by measuring a range of inflammatory markers. Biomass smoke samples were collected during cooking periods in rural households from four different regions of Nepal located at the various altitude ranging from 200 m to 3900 m above sea level. Cultured human bronchial epithelial cells and an ex vivo human lung explant model were stimulated with the smoke extract samples. Inflammatory responses were assessed in cell and tissue culture supernatant after 48 hours stimulation using Luminex analysis to measure levels of 21 chemokines, growth factors and cytokines. Initial results with samples from one site showed that exposure to biomass smoke extract is proinflammatory resulting in the production of significant amounts of inflammatory markers including IL-8, IL-6, TNF- $\alpha$ , GM-CSF and IL-1 $\beta$ , with  $\sim$ 4.5 fold increase in IL-8, IL-6, GM-CSF and a 34 fold increase in TNF- $\alpha$  in epithelial cell cultures. Similarly, in lung tissue, the fold increase for IL-8, IL-6, GM-CSF and IL-1  $\beta$  was  $\sim$ 1.5 fold and for TNF-  $\alpha$  was 4 fold. Current experiments are focusing on the potential effects of altitudinal variation on the biomass smoke extracts used to measure these responses. However, our preliminary data indicate that short-term exposure to biomass smoke causes airway inflammation and suggest this effect may underlie the association seen in epidemiological studies between HAP and respiratory diseases.

## S03.03A. Filling in the Gaps: Maximizing Data Linkages to Enhance Environmental Health Studies

### S03.03.01. Enhancing a Historical U.S. Industrial Emissions Database for Exposure Modeling

**Abstract:** Background: Regulatory databases can provide a useful framework for environmental exposure assessment, but may lack information needed to estimate exposures for epidemiologic studies. Methods: We previously implemented multiple strategies to verify facility locations in a U.S. regulatory database of industrial polychlorinated dibenzo-p-dioxin and dibenzofuran (PCDD/F)-emitting sources (N=4,478). Recent efforts used geographic information systems and deep learning methods to extract information from aerial and satellite imagery and other resources to characterize smokestack features for future exposure modeling. To estimate smokestack height, we processed a sample of image pairs and queried the output of a digital surface model to derive height above ground. We validated these results via manual comparison to available imagery and other reference materials. Linkages to publicly available ancillary datasets (e.g., meteorology) are ongoing. Results: Overall agreement in smokestack location between multiple previous reviews was >83%. Preliminary efforts to estimate smokestack height using photogrammetry indicate good feasibility for this approach (elevation of the stack, ground, and neighboring structures within expectation compared to reference), although some manual adjustment was required to account for tall buildings exceeding the local topographic variation. Next steps include training a deep learning model to automate this process for the entire database. We will discuss challenges and practical implications of these efforts for a case-control study of non-Hodgkin lymphoma in 4 areas of the U.S. Conclusion: We have verified and supplemented key exposure-related information in a database of PCDD/F sources, improving its utility for epidemiologic studies. Further enhancements may leverage available multi-dimensional data and automated building feature detection and extraction on a larger scale.

### **S03.03.02. Modeling Nitrate Concentrations in Private Wells Using Machine Learning Methods**

Mary Ward

*Mary H. Ward<sup>1</sup>, David C. Wheeler<sup>2</sup>, Bernard T. Nolan<sup>3</sup>, Kyle Messier<sup>4</sup>, Rena R. Jones<sup>1</sup>, Abigail Flory<sup>5</sup>*

- 4. University of Texas, Austin, TX, United States.*
- 5. Westat, Inc., Rockville, MD, United States.*

**Abstract:** Background: Water sampling in large cohort studies is usually not feasible. Public water supplies are monitored but data for private wells are sparse. Methods: We developed models to predict nitrate in private wells for the Agricultural Health Study, a cohort of farmers and their spouses in Iowa and North Carolina (NC). About 60% of the cohort used private wells for their drinking water at enrollment in 1993-97. In Iowa and NC respectively, 34,084 and 22,059 nitrate measurements were available through programs for private well owners and water quality surveys. We split the data into training and testing sets to fit and evaluate both continuous and classification models of nitrate concentrations in each state. Input variables included well depth, land use, nitrogen inputs, soil and aquifer characteristics, distance to sinkholes, animal feeding operations (AFOs), meteorology, and other factors. We compared prediction performance of several modeling approaches including random forests, regression trees, and kriging. Results: In both states, a random forest model performed best. In Iowa, the most important predictor of nitrate was well depth; other important variables included distance to nearest sinkhole, soil and aquifer characteristics, distance to nearest AFO, and agricultural land area within 1 km. The final model contained 66 variables. Based on testing data, sensitivity was 67% and specificity was 86% for a 5 mg/L NO<sub>3</sub>-N cut point, ½ the regulatory limit. Thirteen percent of Iowa participants' wells were >10 mg/l. Nitrate concentrations in NC wells were lower than in Iowa and there were fewer predictor variables available. However, we found similar important variables such as well depth, land use, AFOs, and soils. Conclusions: Modeling water contaminants in epidemiologic studies is feasible but local predictors of nitrate in groundwater are key to model performance.

### **S03.03.03. Investigating Multiple Chemical and Contextual Exposures in the Nurses' Health Studies**

Abstract: The Nurses' Health Study and Nurses' Health Study II are U.S.-based prospective cohort studies with decades of follow-up obtained using mailed questionnaires administered every two years. The resultant updated residential address history provides an opportunity to assess health effects of multiple environmental and contextual risk factors in adulthood. We have added numerous residence-level spatiotemporal data on chemical and contextual exposures to the detailed individual-level personal exposures collected on the questionnaires. To date, we have taken advantage of publically available data, purchased data processed by third parties, and developed sophisticated spatiotemporal models at various scales to assess levels of air pollution, temperature, ultraviolet radiation, greenness, walkability, population density, and socioeconomic factors. We also have assessed spatial variation in light at night (LAN), noise, dioxin emissions, and radon. Our breadth of environmental and contextual variables is continually expanding as new data sources come to our attention at higher spatial and temporal resolutions or as new exposures emerge. This georeferenced resource has opened up new opportunities to study environmental etiology of a host of chronic diseases, information on which is obtained originally by self-report during routine follow-up, supplemented by targeted questions and medical record review as appropriate. In this presentation, we discuss the opportunities and challenges of linking environmental and contextual variables to an existing epidemiologic cohort, potential measurement error concerns, as well as approaches to consider these exposures simultaneously with each other and other lifestyle and social variables.

### **S03.03.04. Investigating the Role of Environmental Exposures in Prospective Cohorts: The German National Cohort**

Alexandra Schneider

*Annette Peters<sup>1</sup>, Alexandra E. Schneider<sup>1</sup>*

*1. Helmholtz Zentrum München, Neuherberg, Germany.*

Abstract: The German National Cohort is a multicenter study prospectively assessing the health of 200,000 adults aged 20 to 69, recruited since 2014 and re-examined starting in 2019. Currently, more than 150,000 participants have been recruited in 18 study centers within Germany as of March 2018. The study centers serve major urban areas (i.e. Berlin), mid-size regional centers (i.e. Augsburg) and often are expanding into the surrounding rural counties. As part of a "data freeze", data of the first 100,000 participants is currently undergoing quality assurance. Use of address data to integrate georeferenced information and biomaterials from external databases will be discussed. These databases include modelled air pollution, microclimates, UV, greenness, built environment, and noise. These data are part of already collected databases within national and European programs or will be collected in dedicated programs.

### **S03.03.05. Residential History Construction and Application to Etiologic Studies of Environmental Hazards: Lessons Learned**

Peggy Reynolds

*Peggy Reynolds<sup>1</sup>, Susan E. Hurley<sup>1</sup>, Julie VonBehren<sup>1</sup>, David O. Nelson<sup>1</sup>*

*1. Cancer Prevention Institute of California, Berkeley, CA, United States.*

**Abstract:** Large-scale environmental epidemiologic studies often rely on exposure estimates that are based on linkage of residential addresses to georeferenced environmental data. This approach is often limited by a lack of residential histories. This limitation is particularly problematic for the study of diseases such as cancer for which the time period of greatest etiologic relevance may be decades prior to diagnosis. Moreover, for some cancers, such as breast cancer, there are likely certain windows of susceptibility during which women may be especially vulnerable to the toxic effects of environmental hazards. As part of a larger effort to evaluate breast cancer risks associated with a number of environmental hazards in a large on-going breast cancer study, we explored a variety of approaches to construct residential histories. These efforts were undertaken in the California Teachers Study (CTS), a prospective cohort comprised of over 124,000 women living throughout California. Approaches for constructing residential histories included probabilistic record linkages of CTS participants to credit reporting data, statewide vital records data, and county marriage data. For CTS participants who were born in California, California birth records were used to identify where women were born. For the subset of parous women, linkages to birth data were additionally used as a means to identify where women lived at the time they gave birth. Linkages to county marriage data were used to harvest additional surnames to help overcome obstacles posed by surname changes associated with changes in marital status. While these efforts were successful in helping to build residential histories for women prior to entry into the cohort, including for certain critical windows of susceptibility for breast cancer (e.g., during pregnancy and their own pre-/peri-natal development), substantial limitations were encountered. Advantages and limitations of these strategies will be discussed.

S03.03B. Global Environmental and Occupational Health Hubs: Building Sustainable Research Capacity and Collaboration in Low- and Middle-Income Countries to Address Priority Health Threats

**S03.03.07. Neurotoxicant Exposures in Mother/Child Dyads in Suriname: The Caribbean Consortium for Research in Environmental and Occupational Health (CCREOH)**

Firoz Abdoel Wahid

*Maureen Y. Lichtveld<sup>1</sup>, Sigrid MacDonald-Ottevanger<sup>2</sup>, Jeffrey Wickliffe<sup>1</sup>, Paul Ouboter<sup>3</sup>, Firoz Abdoel Wahid<sup>1</sup>, Ashna Hindori-Mohangoo<sup>4</sup>, Emily W. Harville<sup>5</sup>, Anisma Gokoe<sup>1</sup>, Cornelis Zijlmans<sup>2</sup>*

- 1. GEHS, Tulane University School of Public Health and Tropical Medicine, New Orleans, LA, United States.*
- 2. Research Center Academic Hospital Paramaribo, Paramaribo, Suriname.*
- 3. Anton de Kom University Suriname, Paramaribo, Suriname.*
- 4. Perisur (Perinatal Interventions Suriname) Foundation, Paramaribo, Suriname.*
- 5. Epidemiology, Tulane University School of Public Health and Tropical Medicine, New Orleans, LA, United States.*

**Abstract:** Background Suriname, an upper middle-income Caribbean country, faces a triple public health burden: high perinatal mortality, environmental contamination with mercury and pesticides, and a lack of environmental policies. CCREOH examines the impact of exposures to neurotoxicants in 1000 mother-child dyads on birth outcomes and pediatric neurodevelopment. Methods Environmental epidemiologic cohort design, examining the cumulative impact of chemical and non-chemical stressors on birth outcomes and early childhood neurocognitive development. Recruitment sites: Paramaribo, Nickerie, interior. Environmental assessments: Hg, organophosphate pesticides; biospecimen analysis (blood, urine, hair, saliva, cordblood) and psychosocial questionnaires administered at selected trimesters. Neurocognitive and biospecimen analyses at child ages 12, 24, 26, and 48 months. Results Hg hair analysis: N=347: Paramaribo (266), Nickerie (56), interior (25); median levels 0.6 µg/g, 0.7 µg/g, 2.1 µg/g respectively. Interior Hg levels were significantly higher than in Paramaribo or Nickerie (p<0.001). Urine pesticide analysis (N=50): median diethylthiophosphate (DETP) levels of 0.56 ug/L. Of 650 women, 25.7% had EPDS scores ≥12. Women with no education, primary or lower secondary education 2x likely to have EPDS scores ≥12 compared with upper secondary and higher educated women. Endosulfan and lindane residues were present in the most consumed leafy vegetable Tannia. Non-urban and lower educated women had higher tannia intake rates. Discussion Hg levels in interior pregnant women are considerably higher than their coastal peers likely due to Hg-contaminated fish consumption. The number of women with detectable DETP levels was high compared to NHANES standards. Long-term exposures to neurotoxicant mixtures can harm the mother-child dyad.

### **S03.03.08. The Geohealth Program in Peru, with Some Preliminary Results from a Project on Clean Cookstoves**

Magdalena Fandiño Del Rio

*Magdalena Fandiño Del Rio<sup>1</sup>, Josiah Kephart<sup>1</sup>, Kyle Steenland<sup>2</sup>, Gustavo F. Gonzales<sup>3</sup>, William Checkley<sup>4</sup>, Kirsten Koehler<sup>1</sup>*

- 4. School of Medicine, Johns Hopkins University, Baltimore, MD, United States.*

Abstract: The GEOHealth program in Peru with links to Bolivia and Ecuador, responds to training and research needs of the region. The main training activities consists of short, medium, and long term educational opportunities for more than 40 environmental health researchers. The research involves 3 projects: 1) predicting the areas in Peru where infant diarrhea will be most increased due to climate change through models that combine rotavirus vaccination, access to water/sanitation, temperature, and poverty data; 2) a time-series study of cardiorespiratory emergency room visits in Lima in relation to outdoor air pollution, using an air quality model which predicts spatially resolved fine particulate matter (PM<sub>2.5</sub>) based on ground observations, satellite remote sensing data, and land use information; and 3) our study on household air pollution in relation to cardiovascular outcomes, within a clean fuel intervention trial. Household air pollution is a leading risk factor for preventable diseases and among the largest environmental contributors to the global disease burden. Previous interventions with improved cookstoves have not markedly lowered PM<sub>2.5</sub> and shown only limited improvements on health. As a result, recent efforts are focusing on cleaner fuels such as liquefied petroleum gas (LPG). A randomized controlled field trial of a clean cookstove intervention is enrolling 180 female participants and providing free LPG stoves and fuel to 90 participants. We are collecting 48-hour measurements of indoor air concentrations of PM<sub>2.5</sub> in the kitchen. Preliminary data shows daily average kitchen PM<sub>2.5</sub> concentrations of 500 µg/m<sup>3</sup> for baseline emissions of biomass fuel users (n=70). We observed reductions of about 90% for PM<sub>2.5</sub> concentrations inside the kitchen after 3 months of LPG stove use (n=20). Results of this trial will inform the feasibility of LPG stove replacement programs to reduce HAP and improve health in resource-limited settings such as Peru.

### **S03.03.09. The Michigan-West Africa Geohealth Hub: Environmental Exposures Due to Informal E-Waste Recycling Activities and the Health of Workers**

Julius Fobil

*Julius Fobil<sup>1</sup>, Nil Basu<sup>2</sup>, Stuart Batterman<sup>3</sup>, Thomas Robins<sup>3</sup>*

*3. Department of Environmental Health Sciences, University of Michigan School of Public Health, Ann Arbor, MI, United States.*

**Abstract: Overview:** The West Africa-Michigan CHARTER II GEOHealth Hub, jointly funded by the US NIH/FIC and Canada's IDRC, integrates research and research training activities of West African Anglophone and Francophone institutions, with support from the University of Michigan and McGill University. **Research Goal:** To increase multi-disciplinary understanding of the risks associated with waste recycling, and to use study findings to inform evidence-based implementation activities and policy options at multi-levels. **Specific Objectives:** Include: 1) characterize work-related, time-varying, job-specific exposures of electronic waste recycling workers at the Agbogbloshie site, and assess biological markers of dose, to metals, organic compounds, and markers of combustion products; 2) provide estimates of potentially increased lifetime, work-exposure-associated cancer risks; and, 3) evaluate associations of exposures with measures of acute and chronic respiratory morbidity in workers. **Methodology:** A longitudinal design in which we enrolled a combined total of 151 study participants over a 3-week period. We collected and are analyzing, repeated measures across seasons for each participant: 1) biological samples for a) metals, b) organic compounds including flame retardants, polycyclic aromatic hydrocarbons, dioxin-related compounds, and 2) personal air monitoring, through a combination of real-time measurements and analysis of size-specific samples collected on filters, including markers of combustion products. **Results:** Preliminary filter-based data show that e-waste workers have breathing zone PM<sub>2.5</sub> concentrations of  $135 \pm 188 \mu\text{g m}^{-3}$  (mean  $\pm$  st. dev.,  $n = 89$ ) compared to  $45 \pm 18 \mu\text{g m}^{-3}$  ( $n = 43$ ) of controls; these worker exposures are considerably higher than levels obtained using area monitoring at the waste site, e.g.,  $84 \pm 24 \mu\text{g m}^{-3}$  ( $n = 9$ ). Based on real-time measurements, burning tasks resulted in exceptionally high PM<sub>2.5</sub> exposures.

### **S03.03.10. Eastern African Geohealth Hub: Overall Status and Research Findings from Ethiopia and Uganda**

- 7. University of Colorado, Denver, CO, United States.*

Abstract: The GEOHealth Hub for Eastern Africa is tackling growing challenges from environmental and occupational health hazards through research on air pollution in Ethiopia, Uganda, Rwanda and Kenya. In each country, Children's Health Studies (CHS), modeled after the Southern California Children's Health Study, and daily mortality/morbidity time series studies are being conducted. These activities are co-ordinated with training workshops around health/exposure assessment and data analysis and also mentored training to cohorts of African scientists. We present findings from the just completed CHS in Addis Ababa, Ethiopia, and initial findings from the ongoing CHS in Kampala, Uganda. Both studies followed a multi-level design based on school-children from ten sub-cities, representing a diverse pollution profile due to variations in levels of traffic-related, industrial and indoor pollution sources. In Ethiopia, lung function tests (LFT) were performed at schools on 1086 children, 88.5% of whom had completed the LFT, out of which 89.4% had acceptable performance. About 97% of the tested children had FEV1/FVC >70%, 88% > 80%. Based on questionnaires (n=969), mean age was 10 years (SD=1.0; Range=9-13) with 55% females; majority of mothers have no education (80%), while 54% and 80% of mothers and fathers, respectively, were employed. The proportions of reported respiratory illness were generally low and varied by typology. Charcoal and electricity are the most common types of fuel for all meals while Injera baking mainly involved electricity and wood. Most households (78%) used charcoal for traditional coffee ceremony. The child was present at 61-91% of homes during cooking. PM2.5 levels were measured at study schools using E-samplers and showed wide spatial variations. Household air pollution levels are measured using fixed and personal monitors at strategically selected sites of 30% of homes to enable spatio-temporal modeling for estimation of exposure for all study homes.

### **S03.03.11. Establishing a Hub for Environmental and Occupational Health Research and Capacity Building in India**

Prabhakaran Dorairaj

*Prabhakaran Dorairaj<sup>1</sup>, Joel D. Schwartz<sup>2</sup>, Richard Cash<sup>4</sup>, Srinath Reddy<sup>3</sup>*

- 1. Centre for Chronic Disease Control, New Delhi, India.*
- 2. Environmental Health, Harvard TH Chan School of Public Health, Boston, MA, United States.*
- 3. Public Health Foundation of India, New Delhi, India.*
- 4. Global Health, Harvard TH Chan School of Public Health, Boston, MA, United States.*

Abstract: In the last 25 years, India has experienced rapid economic growth, industrialization and urbanization, which has resulted in high levels of air pollution exposure across major urban centres. The World Health Organization's list of cities with the highest levels of ambient air pollution regularly features over a dozen Indian cities in its top 30, and the Global Burden of Disease estimates rank air pollution exposure among the most important risk factors contributing to poor health outcomes in Indians. Till date, however, much of the research on ambient air pollution and health outcomes, specifically on NCDs has been carried out developed countries, failing to capture the complex environments in which Low and Middle Income Countries (LMICs) function with their multitude of sources, and manifold higher exposure levels. To address this, the Centre for Chronic Disease Control, Public Health Foundation of India, and the Harvard TH Chan School of Public Health established a GEOHealth Hub to examine the links between ambient air pollution and cardiometabolic diseases and risk factors. The hub builds on the work of the CARRS cohort, functional since 2010, by carrying out retrospective associations to build the evidence base for AP & CVD risk factors and outcomes in LMICs. Simultaneously, to build the necessary capacity to carry out the proposed research aims of the hub, and to build a cadre of trained environmental health researchers and policymakers, the Hub is also carrying out a series of short, medium and long-term capacity building initiatives ranging from in-person intensive week-long training programs to Master's level training at HSPH. Till date, over 225 individuals have been trained across 50 institutions in India and neighboring countries. With strong linkages to the Indian health system and the engagement of multiple local partners, the Hub aims to characterize a key environmental threat affecting Indians, and drive policy to address this threat.

### **S03.03.12. Geohealth Hub: Improving Agricultural Health in Southeast Asia**

Pornpimol Kongtip

*Pornpimol Kongtip<sup>1</sup>, Noppanun Nankongnab<sup>1</sup>, Susan Woskie<sup>2</sup>*

*1. Department of Occupational Health and Safety, Faculty of Public Health, Mahidol University, Bangkok, Thailand.*

*2. Department of Public Health, University of Massachusetts Lowell, Lowell, MA, United States.*

Abstract: Forty percent of Thai people are engaged in agriculture. The CWEND GEOHealth Hub in Southeast Asia has focused on measuring occupational exposures and health impacts among agricultural workers. We have recruited farmers that use chemical pesticides and fertilizers and organic farmers to investigate whether they are significantly different in working conditions, musculoskeletal disorders, accidents, and a range of health problems, including metabolic disorders. In comparing the general health of organic and chemical use farmers, we found that the chemical use farmers had significantly higher BMI, waist circumference, body fat%, triglyceride, total cholesterol, LDL and blood pressure than the organic farmers. The organic farmers had significantly higher musculoskeletal disorders of the wrist/hands, fingers, upper back, hip and ankle/feet than the chemical farmers did. Chemical induced hearing loss was investigated among farmers exposed to both noise from agricultural machines and pesticides and compared to organic farmers exposed to only noise and to farmers with neither exposure. Audiometric testing of the high frequencies showed that as cumulative exposures to both noise and to pesticides increased, farmers had a significantly higher risk of hearing loss, suggesting an ototoxic effect of pesticides. Organophosphate pesticides (OP) and paraquat were measured in the meconium of newborn babies where we found 98.5% of samples had OP residues and 55% of the samples had paraquat residues. The incidence of kidney damage was investigated among sugarcane cutters using biomarker measurements (NGAL) pre and post shift. We found that NGAL significantly increased across the workshift, suggesting kidney damage may be occurring. Through the research training and mentoring component of the GEOHealth Hub, we are building capacity for occupational and environmental health research that will inform changes to policy and practice in agriculture in Southeast Asia.

### **S03.03.13. The Bangladesh Geohealth Hub: Household Air Pollution, Climate Change and Garment Industry Work**

4. Department of Public Health and Informatics, Bangabandhu Sheikh Mujib Medical University (BSMMU), Dhaka, Bangladesh.
5. School of Kinesiology and Health Science, Faculty of Health, York University, Toronto, ON, Canada.
6. Mailman School of Public Health, Columbia University, New York, NY, United States.
7. Department of Public Health Sciences, The University of Chicago, Chicago, IL, United States.

Abstract: Household air pollution (HAP) is a global public health problem and less well-studied in developing countries. The overall goal of Bangladesh Hub is to conduct a population-based study (n=600) to examine effects of HAP on preclinical markers of cardiovascular diseases, lung function and immune dysfunction in rural Bangladesh. We will also evaluate impact of clean fuel use (LPG) on health outcomes and conduct two pilot studies to explore health hazards of garment industry work and climate change (temperature and mortality). For capacity development on environmental and occupational health research in Bangladesh, training courses are being conducted at University of Chicago and Bangabandhu Sheikh Mujib Medical University (BSMMU), Bangladesh. We have completed 24hr personal exposure (48hr for a subset) to particulate matter (PM<sub>2.5</sub>), carbon monoxide (CO) and black carbon (BC) on 231 participants using RTI MicroPEM and Lasker CO data logger. On average 48hr concentration of PM<sub>2.5</sub>, CO, BC was 124±108µg<sup>m</sup>-<sup>3</sup>, 1.2±0.9ppm and 4.7±2.1µg<sup>m</sup>-<sup>3</sup> respectively (n=100). Outcome assessments are in progress. Preliminary analysis showed mean carotid intima media thickness, reactive hyperemia index, EKG derived QTc (Bazett's) was 740.9µm, 1.65 and 435ms respectively. Post bronchodilator administered FEV<sub>1</sub>, FVC, FEV<sub>1</sub>/FVC was 2.1L, 2.6L and 80.8% respectively. We observed inverse relationship (not statistically significant) between PM<sub>2.5</sub>>100µg<sup>m</sup>-<sup>3</sup> and BC>3µg<sup>m</sup>-<sup>3</sup> with lung function parameters in adjusted models. Cell phenotyping (done by flow cytometry) in women with high PM<sub>2.5</sub> exposure (n=8, 191±70µg<sup>m</sup>-<sup>3</sup>) had lower percentage of T helper cells, higher Treg cells compared to women with low PM<sub>2.5</sub> exposure (n=8; 63±26µg<sup>m</sup>-<sup>3</sup>). An indication of imbalance in both cellular and humoral immunity in response to HAP was observed. Three Bangladeshi candidates attended short courses and three others are in one year post-doctoral training at University of Chicago. Several short courses were organized by BSMMU.

S03.03C. Milestones in Air Pollution Epidemiology: A Symposium in Honour of Dr. Richard T. Burnett

**S03.03.14. Milestones in Air Pollution Epidemiology: Introduction to a Symposium in Honour of Dr. Richard T. Burnett**

Aaron Cohen

*Aaron J. Cohen<sup>1</sup>, Daniel Krewski<sup>2</sup>*

*1. Health Effects Institute, Boston, MA, United States.*

*2. McLaughlin Centre for Population Health Risk Assessment, University of Ottawa, Ottawa, ON, Canada.*

Abstract: Developments in epidemiologic and statistical methods over the past two decades have enabled quantification of adverse effects of long-term exposure to ambient air pollution, and expert opinion now considers these effects to be causal. Based on this evidence ambient air pollution has now been estimated to be among the leading risk factors for global mortality from non-communicable disease, providing a firm foundation for policy action by national governments and international organizations such as WHO and World Bank. For over 25 years Dr. Richard Burnett of Health Canada has been in the forefront of these developments, playing a leading role in advancing statistical methods for air pollution epidemiology and policy analysis. The symposium highlights milestones in air pollution research to which Dr. Burnett has contributed, summarizing past work, current status and prospects for further progress, and acknowledging the role that public funding of scientific research and support of scientists in government plays in advancing public health. Following a brief introduction by session organizers highlighting Dr. Burnett's contributions, leading air pollution epidemiologists and collaborators of Dr. Burnett discuss research that has advanced epidemiologic knowledge. In conclusion, Dr. Burnett will comment briefly on the future of air pollution epidemiology.

### **S03.03.15. Assessing Long-Term Health Effects of Air Pollution with Advanced Spatial Models**

Michael Jerrett

*Michael Jerrett<sup>1</sup>*

*1. Environmental Health Sciences, UCLA, Santa Monica, CA, United States.*

Abstract: Near the end of the last millennium, relatively few studies on the long-term health effects of air pollution had been undertaken. Two studies were effectively being used for setting government regulations designed to protect public health, namely the American Cancer Society Cancer (ACS) Cancer Prevention II Cohort Study and the Harvard 6-Cities Study. These studies came under increasing scrutiny due to their influential role in setting public health regulations in the United States and elsewhere. As a result, the U.S. Congress requested an independent reanalysis of these two studies. The Health Effects Institute administered the study, which was led by Drs. Krewski and Burnett. Working with fellow statistician Dr. Renjun Ma, Dr. Burnett developed a new flexible method of estimating the Cox proportional hazards model with allowance for random effects that essentially captured the residual variation not accounted for by the fixed predictors in the model. This allowed for the development of an iterative and powerful new method for investigating and minimizing confounding from our Cox model predictions because we could assess the size of the residual variation in total with the random effects variance, and we could also map out the random effects to search for spatial patterns that would represent potentially important missing confounders. This led to a 15-year endeavor to refine these models with the development of new random effects software that we used to assess the long-term effects of air pollution in the ACS cohort and subsequently several other cohorts. In this presentation, I will introduce the random effects method and show several examples that illustrate the capacity of this method to defend against residual confounding and to ultimately produce the sound science required to support regulatory standards and health impact assessments.

### **S03.03.16. Analyses of Air Pollution and Mortality in the American Cancer Society Cancer Prevention Study-II**

Michelle Turner

*Michelle C. Turner<sup>1</sup>*

*1. Barcelona Institute for Global Health (ISGlobal), Barcelona, Spain.*

Abstract: Over the past two decades, the American Cancer Society Cancer Prevention Study-II (CPS-II) has provided valuable information regarding the mortality health effects of long-term exposure to ambient air pollution. The CPS-II is a large-scale prospective cohort study of nearly 1.2 million Americans followed since 1982. Associations of all-cause and cause-specific mortality have been examined in detail with increasing: length of follow-up time, numbers of included participants and observed deaths, and refinement of estimates of long-term exposure to ambient particulate and gaseous air pollutants and statistical modelling approaches over time. Ambient air pollution exposure estimates have ranged from those based on available central monitoring data aggregated at Metropolitan Area level through to more recent approaches based on remote sensing data, or geostatistical or hybrid models at much finer geographic units of scale. Source-related components of fine particulate matter (PM<sub>2.5</sub>) were also examined in other recent work. Epidemiological analyses have been extended to consider spatial autocorrelation and multiple levels of data within a random effects Cox model, interactions of PM<sub>2.5</sub> and cigarette smoking for both lung cancer and cardiovascular mortality, as well as evaluation of new mortality endpoints, including cancer mortality at 29 sites beyond the lung. Finally, the CPS-II has contributed important exposure-response data for application to disease burden assessments, including in both integrated risk functions, as well as in a new global exposure mortality model based only on cohort studies of ambient air pollution. This presentation will highlight key contributions of Dr. Burnett in independent re-analyses and extended analyses of the CPS-II and highlight major research findings with a focus on the most recent and ongoing work.

### **S03.03.17. Reflections on the Canadian CanCHEC Cohort: Where We've Been and Where We Are Going**

Paul Villeneuve

*Paul Villeneuve<sup>1</sup>, Toyib Olaniyan<sup>1</sup>, Daniel Crouse<sup>3</sup>, Scott Weichenthal<sup>2</sup>, Hwashin Shin<sup>4</sup>, Lauren Pinault<sup>5</sup>, Michael Tjepkema<sup>5</sup>*

- 1. Health Sciences, Carleton University, Ottawa, ON, Canada.*
- 2. McGill University, Montreal, QC, Canada.*
- 3. University of New Brunswick, Fredericton, NB, Canada.*
- 4. Health Canada, Ottawa, ON, Canada.*
- 5. Statistics Canada, Ottawa, ON, Canada.*

**Abstract:** The Canadian Census Health and Environment Cohort (CanCHEC) was developed to advance the scientific knowledge about the impacts of prolonged exposure to low-levels of ambient air pollution. Initially, this large-scale cohort consisted of the 20% of Canadian households who were mandated to complete the more detailed long-form census in 1991. Dr. Burnett played a prominent role in the development of the cohort which has since been extended to include those who completed the long-form census in 1996, 2001, and 2006. Probabilistic record linkage of these cohorts were undertaken to link these individuals to Canadian income tax, mortality and cancer registry data. Linkages to the tax databases allowed for the determination of place of residence on an annual basis. Combined, these cohorts include nearly 13 million Canadians (37%) and approximately 1.7 million deaths identified during follow-up. Estimates of ambient air pollution concentrations have been assigned to cohort subjects based on their residential postal codes using a variety of methods including fixed-site monitoring, land use regression, and remote sensing techniques. Analyses of the CanCHEC have provided insights on how long term-exposure to low levels of ambient pollution is associated with cause-specific mortality. This presentation will highlight the contributions of Dr. Burnett with respect to the major research findings for air pollution that have been obtained from this cohort. These include estimates for associations between ambient air pollution concentration and mortality with respect to: (i) the shape of the exposure-response curve, (ii) oxidative burden of fine particulate matter, (iii) methods to indirectly adjust for the impacts of missing covariates, and (iv) methods to account for within- and between-city variations in risk. Lastly, this presentation will highlight ongoing and future research activities using the CanCHEC.

### **S03.03.18. Air Pollution Risk Functions and Estimates of Burden of Disease**

C. Arden Pope

*C. Arden Pope<sup>1</sup>*

*1. Brigham Young University, Provo, UT, United States.*

Abstract: Over the last 25 years there has been a growing literature providing evidence that long-term exposure to air pollution contributes to the risk of cardiopulmonary morbidity and mortality. Dr. Rick Burnett has made many important contributions to this literature, including primary roles in the various analyses of the American Cancer Society CPS-II cohort and the development of and analysis of the Canadian CanCHEC cohort. However, another remarkable contribution includes his development of well-defined and flexible risk functions for use in estimating the burden of disease attributable to long-term exposure to air pollution. This presentation will focus on Dr. Burnett's leadership and ongoing creative roles in developing well-defined and flexible risk functions, including functions that integrate information from studies of ambient air pollution, second hand cigarette smoke, and active smoking as well as meta-analytic approaches that use evidence from multiple studies from the growing literature.

S03.03D. The Benefit of Sharing Data for Unravelling the Complex Issue of Combined Exposures to Multiple Chemicals and their Effects to Humans and the Environment and In Support of Policies in EU and Globally

**S03.03.20. IPCHEM Serving EU and International Policies on Chemicals, Environment and Health: Policy Background and Objectives**

Stylianos Kephelopoulos

*Peter Korytar<sup>2</sup>, Frans Verstraete<sup>3</sup>, Maria Pilar Aguar Fernandez<sup>4</sup>, Sofie Norager<sup>4</sup>, Stylianos Kephelopoulos<sup>1</sup>*

- 1. EUROPEAN COMMISSION, JOINT RESEARCH CENTRE, ISPRA, Italy.*
- 2. EUROPEAN COMMISSION, DG ENV, Bruxelles, Belgium.*
- 3. EUROPEAN COMMISSION, DG SANTE, Bruxelles, Belgium.*
- 4. EUROPEAN COMMISSION, DG RTD, Bruxelles, Belgium.*

Abstract: This presentation will provide the policy background and explain the objectives of IPChem as the European Commission's reference access point for searching, accessing and retrieving chemical occurrence data across various media (e.g. environment, humans, food/feed, indoor air and consumer products). It will outline how IPCHEM helps to fill the knowledge gap on chemical exposure and its burden on health and the environment, while streamlining the efforts to improve the way in which data, information and knowledge are gathered, managed, shared and preserved. IPCHEM operates via a continuously expanding strategic partnership that involves European Commission Services, EU Agencies, EU Member States and synergistic developments with important stakeholders on a global scale.

### **S03.03.21. The IPCHEM Platform: Main Tools and Functionalities, Data Integration Status, On-Going and Planned Activities, Impact and Recognition**

Stylios Kephelopoulos

*Silvia Dalla Costa<sup>1</sup>, Stylios Kephelopoulos<sup>1</sup>*

*1. EUROPEAN COMMISSION, JOINT RESEARCH CENTRE, ISPRA, Italy.*

Abstract: This presentation will outline the main tools and functionalities, the data integration status, the on-going and planned activities (including synergistic developments across the globe) and the so far received impact and recognition of the European Commission's Information Platform for Chemical Monitoring (IPCHEM). The focus will be on the IPCHEM's innovative principles and approaches for data management and visualisation which: (a) ease the task of accessing, retrieving, using and comparing chemical monitoring data in a coherent and efficient way; (b) enable a fast track and low cost system for interconnecting and harmonising on-the-fly remotely accessible data sources pertaining to different policy domains and scientific disciplines; (c) puts emphasis on data quality control rules which are embedded into the IPCHEM's engine and mechanism for boosting data standardisation and harmonisation.

### **S03.03.22. IPCHEM Supporting the Assessment of Chemical Mixtures**

Jacob Klaveren

*Jacob V. Klaveren<sup>1</sup>*

*1. RIVM, Bilthoven, Netherlands.*

Abstract: Humans and wildlife can be exposed to an infinite number of different combinations of chemicals in mixtures via food, feed, consumer products and the environment, which might impact their health. In order to adequately address combined exposures to multiple chemicals, a sound understanding of co-exposure scenarios is needed, which can be greatly enhanced by the use of monitoring data. The results of the workshop "IPCHEM supporting the assessment of Chemical Mixtures" will be presented, where European experts in the area of assessment of chemical mixtures gathered in December 2017 to discuss how IPCHEM can support the assessment of chemical mixtures in its current format and how it should further develop to facilitate co-exposure assessments even further.

### **S03.03.23. Experiences of the German Environment Agency in Sharing Data Via IPCHEM for Further Improving Human Health and Protecting the Environment**

André Conrad

*André Conrad<sup>1</sup>, Maria Rüther<sup>1</sup>, Gerlinde Knetsch<sup>1</sup>, Anette Küster<sup>1</sup>, Marike Kolossa-Gehring<sup>1</sup>*

*1. German Environment Agency (UBA), Dessau-Roßlau / Berlin, Germany.*

**Abstract:** The German Environment Agency (UBA) is Germany's federal agency for environmental protection. UBA collects various monitoring data to document the state of the environment and human exposure to pollutants, investigating associations, making projections, and giving policy advice. So far, UBA has contributed three data collections to IPCHEM: 1) Data of the German Environmental Specimen Bank (ESB) integrated in IPCHEM demonstrate the success of regulating chemicals like Hexachlorobenzene (HCB), as data show a substantial decrease of HCB in blood plasma. Moreover, the ESB documents pollutant levels in different environmental compartments. These data are a basis for further developing monitoring and regulatory activities. 2) Monitoring data from the POP-Dioxin database available via IPCHEM elucidate time trends concerning dioxins and furans as well as polychlorinated biphenyls (PCB) in Germany. This data yield new information on relevant sources and sinks of these compounds. 3) UBA's "database on pharmaceuticals in the environment" listed in IPCHEM was generated by a literature search of more than 1,000 publications. As one result, the analgesic Diclofenac was reported to be found in the environment of 50 countries, with some levels exceeding predicted no-effect concentrations (PNEC). Challenges of contributing data to IPCHEM are additional data transformation efforts and keeping data from ongoing monitoring programs up-to-date. An important opportunity related to IPCHEM participation is fully tapping the value of data for science and policy-making by putting them into a broader context and making them widely accessible. Increasing international visibility of own activities is another key benefit. Future UBA contributions to IPCHEM are i.a. indoor air quality data of the German Environmental Survey (GerES) and data from the HBM4EU initiative.

### **S03.03.24. IPCHEM as Reference Platform for the HBM4EU Project: Coordinating and Advancing Human Biomonitoring in Europe to Provide Evidence for Chemical Policy Making**

Catherine Ganzleben

*Catherine Ganzleben<sup>1</sup>, Greet Schoeters<sup>2</sup>, Marike Kolossa-Gehring<sup>3</sup>*

*1. European Environment Agency, Copenhagen, Denmark.*

*2. VITO, Antwerp, Belgium.*

*3. German Environment Agency, Berlin, Germany.*

Abstract: HBM4EU was launched in January 2017 to coordinate and advance human biomonitoring across 28 partner countries, in order to generate coherent and representative data in support of chemical policy-making in Europe. A key element of the work is the management of human biomonitoring data, including data transfer, access to data and respecting data protection legislation and ethics requirements. IPCHEM provides the tool for data management under HBM4EU. At the same time, HBM4EU identifies existing datasets and generates new data for inclusion in IPCHEM, enriching the platform. The presentation will highlight the synergies between these two EU initiatives, as well as describing the challenges encountered in the start-up phase of managing data under HBM4EU.

**S03.03.26. The U.S. EPA Activities and Information Systems Used for Chemical Exposure Screening, Modelling and Prioritisation and Risk-Based Decision Making: Needs, Challenges and Opportunities for Data Sharing and Interoperability of Tools on Global Scale Including**

Katherine Phillips

*Katherine Phillips<sup>1</sup>, Kristin Isaacs<sup>1</sup>, Kathie Dionisio<sup>1</sup>, John Wambaugh<sup>2</sup>, Antony Williams<sup>2</sup>*

*1. National Exposure Research Laboratory, US EPA, RTP, NC, United States.*

*2. National Center for Computational Toxicology, US EPA, RTP, NC, United States.*

Abstract: Within the US EPA Office of Research and Development's (ORD's) Chemicals for Safety and Sustainability (CSS) research program, efforts are underway to provide information that is useful for the risk-based prioritization of thousands of chemicals, particularly those found in consumer products. The information has been made publicly available through ORD's CompTox Chemistry Dashboard (<https://comptox.epa.gov>). In this presentation the research efforts that contribute to the collection and curation of consumer product formulations, article compositions and ingredient uses will be discussed. This information is obtained through both automated collection techniques from manufacturer-supplied documents and measurement of chemicals via suspect screening analysis. Finally, predictions from ORD-developed models for such values as physicochemical properties, functional use, product composition, and chemical exposure, which are provided via the Chemistry Dashboard, will be discussed. The views expressed in this abstract are those of the authors and do not necessarily reflect the views or policies of the US Environmental Agency.

### **S03.03.27. Synthesizing Exposure Data for Regulatory Decision Making: The Need for a Centralized Data Warehouse**

Sandra Kuchta

*Sandra Kuchta*<sup>1</sup>

*1. Health Canada, Ottawa, ON, Canada.*

Abstract: The Chemicals Management Plan (CMP) is a Government of Canada initiative aimed at reducing the risk posed by chemicals to Canadians and their environment by assessing substances used in Canada and by taking action on chemicals found to be harmful. Many potential sources of exposure are considered, including but not limited to, environmental media, food, cosmetics, cleaning products, do-it-yourself products, and toys. Data used to estimate exposure to chemical substances come from a variety of sources and can vary widely. The speaker will highlight the need for the development of a global centralized data warehouse to store broad types of exposure data across international jurisdictions for both chemical risk assessment and priority setting. The presentation will include an analysis of exposure data used for the assessment of approximately 3000 chemical priority substances as part of Canada's CMP and will highlight the disparate sources of key chemical-specific exposure data including: monitoring data in air, soil or water; product concentration data; biomonitoring data; food concentration data; and chemical use volumes that are often considered for regulatory risk assessment. This presentation will also illustrate how a centralized data warehouse for exposure will help to increase efficiency of exposure assessment and will lead to increased data sharing and the filling of data gaps. This will be illustrated using examples from the CMP. The types of chemical-specific data that can be compiled and stored in this warehouse will be highlighted, such as environmental and effluent monitoring data, environmental release volumes, empirical phys-chem properties, empirical degradation half-lives, and results of empirical product testing, such as emission and migration rates. Lastly future activities such as advancements in assessing combined exposures as well as potential challenges of data standardization, data quality, and data confidentiality will be discussed.

## S03.03E. Transforming Air and Water Quality Research Into Concrete Actions

### **S03.03.28. The Role of Health-Based Air Quality Guidelines in Transforming Local Policy Actions**

Klea Katsouyanni

*Klea Katsouyanni*<sup>1</sup>

*1. Hygiene, Epidemiology and Medical Statistics, National and Kapodistrian University of Athens, Athens, Greece.*

Abstract: Legal standards for air pollutants concentrations are based on a number of considerations including the cost and the availability of technology for decreasing the levels, socio-economic factors and the effects on the environment and human health. Thus, non exceedance of the legal standards does not necessarily imply the absence of health effects. The World Health Organization provides evidence based air quality guidelines taking into account only the effects on human health. These are periodically revised and updated to reflect the current scientific knowledge. During the first decades they were oriented towards Europe but since 2005 they are global. Are these guidelines useful for policy making? Are they useful for increasing population awareness? Are they a useful tool for scientists seeking to translate their findings into meaningful messages for policy decisions? Reflections on twenty plus years of experience with the formulation of the WHO air quality guidelines will be presented. Issues and problems that came up and were resolved in a specific way will be looked upon critically and an effort to draw conclusions will be made. For example, the considerations which may lead to a change in the reference pollutants and what might be the consequences will be discussed, and, whether a threshold value is necessary even if there is limited evidence for one. Cases where the W.H.O. guidelines have been useful for scientists and policy makers in supporting the case for cleaner air as well as in raising awareness both in policy making bodies and in the general public will be presented.

### **S03.03.29. Shrinking Space, Expanding Time: Challenges in Applying Air Pollution Research Findings at the Local Level**

Ray Copes

*Ray Copes<sup>1</sup>*

*1. PHO/UofT, Toronto, ON, Canada.*

Abstract: . The link between episodes of poor air quality and adverse effects on health is well known to the media, public and policy makers at all levels. The last several decades of air pollution research have made clear the importance of long term exposure to air pollution as a risk factor for chronic diseases. More sophisticated exposure assessment methods have also revealed that gradients of air pollution within communities are important with respect to health risks. While this research has influenced national air quality standards, its incorporation into local decision making has proved more challenging. To some extent this may reflect a lack of familiarity with recent air pollution research on the part of policy makers at the local level. However, it may also reflect some of the inherent challenges in dealing with spatial versus temporal variation as a determinant of health risk.

### **S03.03.30. Lead in Drinking Water: The Slips Twixt Lip and Cup**

Ronnie Levin

*Ronnie Levin<sup>1</sup>*

*1. Environmental Health, Harvard School of Public Health, Boston, MA, United States.*

Abstract: The deleterious effects of lead have been known for centuries, and US EPA has methodically addressed the major sources of lead exposure. Nonetheless, media coverage of blatant violations of the US lead in drinking water rule repeatedly splay across newspapers throughout the country. Each time, regulators and administrators have expressed surprise and shock at the revelations. Each time, the public is assured by local, state and federal officials that processes are in place to remediate and safeguard health, now and in the future. Nonetheless, the evidence stands that EPA's current lead in drinking water standards are inadequate protections, and that strengthened information flow is required at each step of the process to protect the public.

### **S03.03.31. Environmental Public Health Tracking: From Data to Action**

Fuyuen Yip

*Fuyuen Yip<sup>1</sup>*

*1. US Centers for Disease Control and Prevention, Atlanta, GA, United States.*

Abstract: The National Environmental Public Health Tracking Program (Tracking Program) has worked closely with a community of funded state and local health departments to develop the National Environmental Public Health Tracking Network (Tracking Network), an integrated network of environmental health surveillance data-including air, water, and specific health outcome data-at the local, state, and national levels. Application of these data is key to support evidence-based decision-making and public health actions within state and local programs to help promote healthy and informed communities. The Tracking Program continues to enhance the infrastructure of the Tracking Network to support consistent use of its data and program resources to help inform public health actions, with the goal of reducing the burden of environmentally related health conditions. This presentation will highlight how the Tracking data and program resources have been used to inform air and water quality-related public health action at the state and local level.

### **S03.03.32. U.S. EPA Solutions for Energy, Air, Climate, Health (SEARCH) Center: Lessons Learned**

Michelle Bell

*Michelle Bell<sup>1</sup>*

*1. Yale University, New Haven, CT, United States.*

Abstract: While public health research is intended to provide societal benefits, challenges remain in translating science into action and in connecting the scientific community to stakeholders and decision makers. The Solutions for Energy, Air, Climate, and Health (SEARCH) Center is a 5-year interdisciplinary Center of connected research projects funded by the United States Environmental Protection Agency. The main objective of the Center is to investigate emerging energy transitions in the U.S. and the resulting air pollution and health outcomes through air quality modeling, economic modeling, air quality measurements, and epidemiological analysis to characterize factors contributing to emissions, air quality and health. In addition to the scientific research, the Center includes a Policy and Decision-Making Unit. This work is designed to incorporate regulators and policy makers into the scientific process from the earliest design and research stages, rather than only at the end when scientific results are communicated. This presentation will include lessons learned from this process to aid the scientific community's ability to provide decision makers with the most effect information on environmental health.

## O03.04A. Characterizing Long Term Trends in Air Pollution Using Stationary and Low Cost Monitoring

### O03.04.01. Assessment of Temporal and Spatial Trends of Air Pollutants Using Low-Cost Air Quality Sensors in Peñuelas, Puerto Rico

Stephen Reece

*Stephen Reece<sup>1</sup>, Ron Williams<sup>2</sup>, Maribel Colón<sup>2</sup>, Evelyn Huertas<sup>3</sup>, Marie O'Shea<sup>4</sup>, Patricia Sheridan<sup>4</sup>, David Southgate<sup>5</sup>, Gladys Portuondo<sup>5</sup>, Noel Suyas<sup>5</sup>, Barbara Wyrzykowska-Ceradini<sup>6</sup>*

*1. National Exposure Research Laboratory, ORISE Participant hosted by U.S. EPA, Research Triangle Park, NC, United States.*

*2. National Exposure Research Laboratory, U.S. Environmental Protection Agency, Research Triangle Park, NC, United States.*

*5. Desarrollo Integral del Sur, Inc., Ponce, Puerto Rico, United States Minor Outlying Islands.*

*6. Jacobs Technology, Inc., Research Triangle Park, NC, United States.*

**Abstract:** The U.S. Environmental Protection Agency (EPA) is involved in the discovery, evaluation, and application of low-cost air quality sensors to support citizen scientists by directly engaging with them in the pursuit of community-based interests. The recent advancement of low-cost (<\$2,500) air quality sensors has allowed a wide range of stakeholders, including communities, tribes, and industry, to deploy low-cost sensors in a range of applications to better understand local air quality conditions and to supplement regulatory monitoring locations. The low-cost advantage of these sensors enables a network of multiple sensors to be deployed to assess temporal and spatial trends in micro-environments at high-time resolution. Here we present results from the deployment of the EPA developed Citizen Science Air Monitor (CSAM) used to conduct approximately five months (October 2016 - February 2017) of intensive air quality monitoring in an area of Puerto Rico (Tallaboa-Encarnación, Peñuelas) with little historical data on pollutant spatial variability. The CSAMs were constructed by combining various low-cost original equipment manufacturer (OEM) sensors and system integration technologies into a single unit to maximize ease of operation, while meeting a specific research requirement. The CSAMs were distributed across eight locations to collect real-time measurements of the particulate matter size fraction 2.5 micron (PM<sub>2.5</sub>), total volatile organic compounds (tVOCs), and nitrogen dioxide (NO<sub>2</sub>). In addition to the CSAMs, meteorological parameters (wind speed, wind directions, temperature, relative humidity) were obtained from four collocated weather stations. Initial analysis of 24-hour averaged pollutant measurements showed concentrations did not exceed 12.0 µg/m<sup>3</sup>, 60.0 ppb, and 40.0 ppb for PM<sub>2.5</sub>, tVOCs, and NO<sub>2</sub>, respectively. These results highlight the added value provided by low-cost sensors to supplement regulatory monitors despite their known limitations.

### **O03.04.02. Ambient Ultra-Fine Particle Exposure Assessment Based on Mobile and Stationary Monitoring during Fine Dust Season in Stuttgart, Germany**

Tobias Schripp

*Tobias Schripp<sup>1</sup>, Maximilian Braun<sup>1</sup>, Tobias Grein<sup>1</sup>, Patrick Oßwald<sup>1</sup>*

*1. Chemical Analysis, Institute of Combustion Technology (DLR), Stuttgart, Germany.*

Abstract: The air quality in the city of Stuttgart is a topic of high relevance in public media due to the frequent exceedance of guideline values and the resulting discussion on possible diesel car bans. The city features stationary monitoring stations for air quality in the most relevant areas of the city. These stations are expanded by a large sensor network operated by private individuals. Even though the available data on ambient air pollutants is rather comprehensive, the source appointment and mitigation strategies are discussed controversially. In this study, a stationary measuring station was operated for approx. 1 month during "fine dust season" (from October to April) with a series of different particle counters (SMPS, OPS). In addition, mobile measurements by car were performed in downtown Stuttgart and nearby. The car was equipped with an Engine Exhaust Particle Sizer, an Optical Particle Sizer and a Black Carbon Monitor. For a better source appointment, a CLD64 was continuously monitoring the concentration of nitrogen oxides (NO<sub>x</sub>). The stationary particle counter station recorded significantly lower concentrations than the official monitoring station (at a street with heavy traffic) - even though the distance was approx. 500 m. This indicates that the heavily polluted areas have a low extension and are clearly outlined. The mobile measurements support that the official monitoring station is located at the worst air quality position. The particle exposure varies significantly in the area. Based on the lung deposition model of the ICRP, the main fraction of particle mass is deposited in the upper respiratory pathways. However, the particle counter revealed elevated concentrations of particles < 100 nm which are usually not covered by gravimetric analysis. This indicates that particle counters and sensors might be a substantial supplement to regular monitoring stations to assess the real exposure of city dwellers.

### 003.04.03. Source and Potential Health Risk of Trace Metals in the Urban Atmosphere

Chien-Cheng Jung

*Chien-Cheng Jung<sup>1</sup>, Charles C.-K. Chou<sup>1</sup>, Chuan-Yao Lin<sup>1</sup>, Chuan-Chou Shen<sup>2</sup>, Yu-Chi Lin<sup>1</sup>, Yi-Tang Huang<sup>1</sup>, Chao-yang Tsai<sup>1</sup>, Pei-Hsuan Yao<sup>2</sup>, Ci-Rong Huang<sup>2</sup>, Wei-Ju Huang<sup>1</sup>, Mei-June Chen<sup>1</sup>, Shu-Hui Huang<sup>1</sup>, Shuenn-Chin Chang<sup>3</sup>*

1. *Academia Sinica, Taipei, Taiwan.*
2. *National Taiwan University, Taipei, Taiwan.*
3. *Environmental Protection Administration, Taipei, Taiwan.*

**Abstract:** The objective of this study was to assess the seasonal variations and health risks of trace metal levels and investigate whether Pb isotope ratios can be used as an indicator of the source for trace metals. A BGI PQ200 Fine Particulate Sampler was used to collect PM<sub>2.5</sub> on Teflon filters during the summer of 2015 and spring of 2016 in Taipei, Taiwan. The inductively coupled plasma mass spectrophotometer (ICP-MS) and multi-collector ICP-MS were used to analyze the trace metals (As, Cu, Cd, Cr, Mn, Pb, and Zn) and Pb isotopes (<sup>206</sup>Pb, <sup>207</sup>Pb, and <sup>208</sup>Pb), respectively. This study also calculated the potential health risk for trace metals in both summer and spring for different populations. Our data showed that the levels of trace metals were significantly higher in spring than in summer. There were higher non-carcinogenic and carcinogenic risks in spring than in summer through inhalation exposure. All hazard index values were below a safe level (1.0), but the values were higher for children than adults. The lifetime cancer risk values for Cr (VI) exceeded an acceptable level (1E-6) in both spring and summer and the value of As also exceeded the acceptable level in spring. Moreover, the Pb isotope ratios (<sup>206</sup>Pb/<sup>207</sup>Pb and <sup>208</sup>Pb/<sup>207</sup>Pb) were associated with the levels of all trace metals. The results from Pb isotope ratios and backward trajectories model indicated that long-range transport from China was an important contributor of trace metals during the episodes in spring, local emission was a major source in summer. This study suggests that it is necessary to reduce the emissions of trace metals due to higher health risk in Taipei. Pb isotope ratios can be used as an indicator of source for trace metals.

#### **003.04.04. Ozone Chemistry over the Syrian Arab Republic: Impact of the War**

Lyazzat Kulmukanova

*Lyazzat Kulmukanova<sup>1</sup>, Mehdi Amouei Torkmahalleh<sup>1</sup>, Aigerim M. Maksot<sup>1</sup>*

*1. Chemical Engineering, Nazarbayev University, Astana, Kazakhstan.*

Abstract: Ground ozone (O<sub>3</sub>) is a major photochemical air pollutant that has negative effects on both human health and environment, exposure to which results in the development of respiratory diseases and damage to ecosystems. Ozone does not have direct natural or anthropogenic sources of emission and its formation is accounted for the cyclic photochemical reaction between its precursors, nitrogen dioxide (NO<sub>2</sub>) and volatile organic compounds (VOC). This study investigated ozone concentration and chemistry over Syrian cities Deir ez-Zor and Aleppo between 2005 and 2016. These two cities experienced a civil war in 2011 that later on involved other countries. To identify how the trends of NO<sub>2</sub> and VOC were changed due to the war, and subsequently their effect on the ozone formation, the study was divided into two periods, before and after the war. This study was conducted by analyzing Formaldehyde-to-Nitrogen Dioxide ratio (FNR), which is considered to be the main indicator of ozone sensitivity regime. It was observed that starting the war, Aleppo, located on the west of Syria experienced a change of FNR values from the range of 0-1 to 1-2 which represents a shift in ozone sensitivity regime. The city located on the east of the country, Deir ez-Zor, did not experience a considerable change in the regime, as FNR values were maintained above 2 throughout the given period. Such different responses to the presence of the war in the cities of the same country could emphasize that the war has variant effects on the ozone chemistry over the cities due to the intensity of the war interactions and background of the cities. Lastly, it was found that changes in ozone chemistry in Syria due to the war resulted in the similar changes in ozone chemistry in the bordering countries (Turkey and Lebanon), and thus areas of these countries which are close to the borders of Syrian Arab Republic experienced ozone peaks in 2012 and 2016 due to the sharp increases of ozone in Syria itself.

### **003.04.05. Spatial Distribution of Particulate Matter in Winter Nights in Temuco, Chile: A Study of Residential Wood-Burning Impacts Using Mobile Sampling**

Pablo Ruiz-Rudolph

*Pablo Ruiz-Rudolph<sup>1</sup>, Francisco Rubilar<sup>2</sup>, Maria Elisa Quinteros<sup>1</sup>, Karen Cayupi<sup>2</sup>, Siyao Lu<sup>3</sup>, Raquel Jimenez<sup>4</sup>, Juan Pablo Cárdenas<sup>2</sup>, Carola A. Blazquez<sup>5</sup>, Juana Maria Delgado<sup>6</sup>, Roy M. Harrison<sup>6</sup>*

- 1. Institute of Population Health, University of Chile, Santiago, Chile.*
- 2. Instituto del Medio Ambiente, Universidad de la Frontera, Temuco, Chile.*
- 3. Environmental Health Sciences, University of Michigan, Ann Arbor, MI, United States.*
- 4. Environmental Health, Boston University, Boston, MA, United States.*
- 5. Engineering Sciences, Universidad Nacional Andrés Bello, Santiago, Chile.*
- 6. Geography, Earth and Environmental Sciences, University of Birmingham, Birmingham, United Kingdom.*

**Abstract:** Temuco is a city heavily impacted by residential wood-burning, which causes strong episodes of air pollution, particularly in winter. Little is known about the spatial distribution of wood-burning pollutants, and knowing this distribution is key to develop spatial models to be used in study of chronic health effects. The objective of this study is to characterize spatially the distribution of particulate matter in Winter nights in Temuco using measurements. For 20 nights (8pm to 2am) of winter 2016, continuous monitors for particulate matter <2.5  $\mu\text{m}$  (PM<sub>2.5</sub>) and ultrafine particles (UFP) were deployed in a vehicle along with a positioning system. Assigned routes crossing the city and scanning the boroughs were performed using a pair of samplers, while another pair were kept at central site for normalization. Measurements were collapsed by hour and day in spatial grids of 50, 100, 200 y 500 meters side using the mean, standard deviation and the ratio to the central site for each grid cell. Then, pollutant distribution was visually inspected and analyzed using measures of dispersion and heterogeneity. PM<sub>2.5</sub> concentrations were in a range similar those observed at the central site (~50-100  $\mu\text{g m}^{-3}$ ) but with a large spatial variability, with gradients that diminished towards the outskirts of the city. UFP concentrations were in the order of a polluted city (~50.000-100.000 counts  $\text{cm}^{-3}$ ), with the central site being a poor predictor of mobile measurements. Heterogeneity indicators were high for both pollutants, indicating a high spatial variation for both pollutants. In general, it was observed a pattern of increasing PM<sub>2.5</sub> toward residential areas and increasing UFP near highways. In conclusion, mobile sampling seems a useful alternative to study spatial distribution of pollutants in these settings. Produced data can be used to develop spatial models such as Land-Use Regression (LUR models).

## O03.04B. Health Outcomes Associated with Perinatal Exposure to Air Pollution

### O03.04.06. Prenatal Exposure to PM2.5 and Infant Autonomic Nervous System Reactivity: Effect Modification by Sex and Maternal Total Antioxidant Intake during Pregnancy

**Abstract:** The autonomic nervous system (ANS) plays a key role in stress reactivity and is programmed during gestation. We investigated associations between prenatal exposure to fine particulate matter (PM2.5) and infant ANS reactivity during a stress challenge among 239 maternal-infant pairs enrolled in a Boston-based birth cohort. We estimated daily residential PM2.5 using satellite data in combination with land-use regression predictors. At 6 months, we measured parasympathetic nervous system (PNS) activity using continuous ECG and respiration monitoring during the repeated Still Face Paradigm (SFP-R), which is designed to elicit infant stress reactivity and regulation in response to maternal disengagement and interaction. We used multivariable linear regression to examine average PM2.5 exposure across pregnancy in relation to PNS withdrawal and activation, indexed by changes in respiratory sinus arrhythmia (RSA). We grouped infants by 'typical' or 'atypical' patterns of RSA change and used multivariable logistic regression to model associations between PM2.5 and group assignment. We examined interactions with sex and maternal total antioxidant intake during pregnancy, estimated using a food frequency questionnaire. We detected significant 3-way interactions ( $p < 0.01$  across models) between PM2.5, sex, and antioxidants. Among girls with low prenatal antioxidants (<50th percentile), each 10-unit increase in PM2.5 was associated with marginally reduced PNS withdrawal during stress (25% increase in RSA,  $p = 0.06$ ), marginally depressed PNS activation during recovery (24% decrease in RSA,  $p = 0.05$ ), and significantly increased odds of an 'atypical' response pattern (OR: 2.7, 95% CI: 1.2, 5.9). We did not observe significant findings among girls with higher prenatal antioxidants or among boys. Prenatal exposure to PM2.5 may disrupt programming of autonomic stress-response systems among girls. Higher intake of antioxidant-rich foods during pregnancy may protect against these effects.

### **003.04.07. Prenatal Air Pollution and Childhood Allergic Diseases: The Potential Modifying Effect of Adherence to Mediterranean Diet**

Leda Chatzi

**Abstract:** Background: Prenatal exposure to air pollution has been associated with increased risk of childhood asthma and allergies, however, less is known regarding the potential modifying effect of maternal diet during pregnancy in this association. Objectives: To investigate whether prenatal exposure to particulate matter (PM) is associated with childhood eczema, allergic rhinitis (AR) and asthma, and to assess a potential modifying effect by maternal adherence to Mediterranean Diet (MD) using data from the Rhea pregnancy cohort. Methods: Allergic outcomes were evaluated in children at ages 4 (n=809) and 6 (n=567) years old using validated questionnaires. Land-use regression models and back-extrapolation procedures were utilized to estimate outdoor levels of PM<sub>2.5</sub>, PM<sub>10</sub>, and PM<sub>coarse</sub> at home addresses during pregnancy. MD was assessed by a validated food frequency questionnaire, and MD adherence was evaluated using an a priori score. Multivariate logistic regression models were used and interaction terms with MD were added in the model to evaluate any PM by MD effect modification. Results: Overall, prenatal PM exposure was significantly associated with an increased risk of AR and eczema at ages 4 and 6 but not with asthma. Stratified analysis by MD adherence indicated that PM<sub>2.5</sub> exposure was associated with an increased risk of AR and eczema at age 4 (OR, 95%CI: 2.74, 1.47-5.12 and 2.01, 1.02-3.93, respectively) in children of mothers with low MD adherence, whereas this effect was not apparent in children of mothers with high MD adherence (Pinteraction 0.027 and 0.017, respectively). Similarly, PM<sub>coarse</sub> exposure was associated with an increased risk of eczema at both 4 and 6 years old (Pinteraction 0.015 and 0.043, respectively), and PM<sub>10</sub> with eczema at 6 years old only in children of mothers with low MD adherence (Pinteraction 0.033). Conclusion: Maternal adherence to MD may modify the detrimental effect of prenatal air pollution on childhood allergy.

### **O03.04.08. The Associations between Exposure to Fine Particulate Matters during Pregnancy and Early Postnatal Period and Asthma Onset in a Metropolitan Area in Taiwan**

Chau-Ren Jung

**Abstract:** Background/Aim The development of lung is a multi-stage process from conception to early postnatal period, any disruption of the process by pollutants may trigger respiratory morbidity later. Exposure to particulate matters (PM) during both prenatal and postnatal periods may be associated with the increased risk of asthma. We aimed to evaluate the effects of weekly average PM with aerodynamic diameter less than 2.5 $\mu$ m (PM<sub>2.5</sub>) during prenatal and early postnatal periods on asthma and tried to find out the most vulnerable time windows of asthma that would help to elucidate the possible mechanism for effects of PM<sub>2.5</sub> on asthma. Methods A birth cohort study including 184,604 neonates born during 2004-2011 in Taichung city was retrieved from Taiwan Maternal and Child Health Database and followed up until 2014. A highly temporal resolution satellite-based hybrid model has been applied to estimate daily PM<sub>2.5</sub> for each subject. A Cox proportional hazard model combined with the distributed lag non-linear model was performed to evaluate the associations of asthma with weekly average exposure to PM<sub>2.5</sub> during prenatal and early postnatal period. Results Within the birth cohort, there were total 34,336 asthma cases (18.60%), the mean age of infants who received asthma diagnosis was 3.39 $\pm$ 1.78 years. The results reveal that increased exposure to PM<sub>2.5</sub> during 3-6 gestational weeks, 25-36 gestational weeks and during 10-50 weeks after birth were significantly associated with increased incident asthma. Additionally, we observed consistent positive associations of asthma with exposure to PM<sub>2.5</sub> during the prenatal and postnatal period for both males and females. Conclusion Our findings added evidence into the growing literature that both prenatal and postnatal exposures to PM<sub>2.5</sub> are associated with the later development of asthma. The vulnerable time windows may be within early and late gestation that showed a bimodal pattern. Further studies are needed to confirm the vulnerable time windows.

### **003.04.09. CC16 Levels into Adult Life Are Associated with Nitrogen Dioxide Exposure at Birth**

Paloma Beamer

*Paloma Beamer<sup>1</sup>, Melissa Furlong<sup>2</sup>, Stefano Guerra<sup>1</sup>, Nathan Lothrop<sup>1</sup>, Mary Kay O'Rourke<sup>2</sup>, Debra Stern<sup>1</sup>, Jing Zhai<sup>1</sup>, Dean Billheimer<sup>3</sup>, Marilyn Halonen<sup>1</sup>, Anne Wright<sup>1</sup>, Fernando Martinez<sup>1</sup>*

**Abstract:** Children's lung function and growth is adversely associated with exposure to nitrogen dioxide (NO<sub>2</sub>). Lower levels of circulating club cell secretory protein (CC16) in childhood are also associated with subsequent decreased lung function in adolescence and adulthood. Evidence from in vitro and in vivo studies suggests that NO<sub>2</sub> exposure may induce epithelial damage in the lungs and altered club cell proliferation and morphology. Our objective was to determine if increased ambient NO<sub>2</sub> levels at participants' home addresses at birth or age 6 were associated with decreased levels of CC16 from age 6-32 years. Participants were enrolled at birth in the Tucson Children's Respiratory Study and had circulating CC16 measured at least once between age 6-32 years. Annual average estimates of NO<sub>2</sub> were obtained for the address and year corresponding to each participant's home address at birth and at age 6. Linear mixed models were used to determine the association between exposure to NO<sub>2</sub> at birth or age 6 with CC16 levels from age 6-32 years. NO<sub>2</sub> exposures at birth or age 6 were available for 777 children with at least one CC16 measurement from ages 6-32. An interquartile range increase in NO<sub>2</sub> at the children's birth address was associated with a 4.89% (95% CI -9.04, -0.75) decrease in CC16 levels from age 6-32 years. An interquartile range increase in NO<sub>2</sub> at the children's age 6 address was not associated with a decrease in CC16 levels from age 6-32 years (-2.54%, 95% CI -7.03, 1.94). Similar results were obtained after adjusting for potential confounders including maternal smoking (NO<sub>2</sub> at birth -4.83% [95% CI -9.00, -0.66]; NO<sub>2</sub> at age 6 [-1.95%, 95% CI -6.47, 2.56]). Higher exposure to NO<sub>2</sub> at birth is associated with persistently low levels of CC16 from 6-32 years. We speculate that persistently low levels of CC16 may reflect airway injury induced by exposure to NO<sub>2</sub> during critical periods of lung growth, thus predisposing for diminished lung function later in life.

## O03.04C. Multiple Exposures and Development

### O03.04.11. Understanding the Time-Varying Association between Prenatal Metal Exposure Mixtures and Neurodevelopment

Yuri Levin-Schwartz

4. Columbia University, New York, NY, United States.

**Abstract:** Humans are exposed to chemical mixtures at each life stage and their effects can vary over time (i.e. critical windows). We extended weighted quantile sum (WQS) regression, a method designed to assess correlated exposures at a single time point, to estimate the effect of metal mixtures on neurobehavior over multiple time points, their critical windows and the contributions of each mixture component. We assessed neural function using the Rapid Visual Processing (RVP) task from the Cambridge Neuropsychological Test Automated Battery, focusing on latency to correct response and probability of correct response (POCR), in the Programming Research in Obesity, Growth, Environment and Social Stressors cohort in Mexico City. RVP data were gathered from 326 children aged 6-8 years and prenatal metal exposure was quantified using maternal blood at the 2nd and 3rd trimesters. Arsenic (As), cadmium (Cd), cesium (Cs), chromium (Cr), lead (Pb) and antimony (Sb) were selected based on their toxicological profile. Results are adjusted for age, gender, socio-economic status, maternal education and maternal age. In the overall model, the mixture was associated with latency [0.09; 95% CI[0.01, 0.17],  $p < 0.04$ ], driven largely by both 2nd and 3rd trimester Cs (combined weight=54.11%) and Cd (combined weight=20.53%). For POCR, the results were more variable by exposure timing. The overall mixture effect was -0.07 (95% CI[-0.15, 0.01],  $p < 0.08$ ), primarily driven by 3rd trimester Sb (weight=16.6%), Cs (weight=14.1%) and Pb (weight=13.2%), while 2nd trimester Cr contributed 16.7% of the weight. Overall, 3rd trimester metals contributed 58% of the weight and 2nd trimester metals contributed 42%. These results indicate that metal mixtures have unique critical windows and that WQS can be used to assess mixture effects, the contributions of each component, as well as discern time-dependent effects.

### **O03.04.12. Prenatal Exposure to Metals Mixtures and Neurobehavioral Outcomes at Age 7 from the Project Viva Birth Cohort**

Victoria Fruh

**Abstract:** Background: Lead (Pb), manganese (Mn), and methylmercury are known neurotoxic metals and often co-exist in the environment. Less is known about their interactive and joint effects on specific childhood neurobehavioral domains, particularly for prenatal exposure. Aims: To evaluate the joint effects of prenatal exposure to multiple metals on mid-childhood neurobehavior. Methods: We measured Pb, Mn, selenium (Se) and mercury (Hg) concentrations in maternal 2nd trimester erythrocytes from 252 mother-child Project Viva participants in Massachusetts, USA. Parents and teachers rated child behaviors with the Behavior Rating Inventory of Executive Function (BRIEF) during mid-childhood (median 7.7 years). We evaluated joint effects of the metal mixture on neurobehavior using Bayesian Kernel Machine Regression, adjusting for maternal, paternal and child characteristics. Results: Median erythrocyte Pb, Mn, Se, and Hg concentrations were 11 µg/L, 33 µg/L, 205.7 µg/L, 3.6 x 10<sup>-3</sup> µg/L, respectively. We observed worse scores on parent- and teacher-rated scales with simultaneously increasing metal concentrations, suggestive of a joint effect, although not statistically significant. Se was a major contributor to associations for the Global Executive Composite and subscales. With other metals at their median, an IQR increase in ln-Se was associated with a 1.3 point increase (95% CI=0.02, 2.6) on the parent-rated organization of materials (OM) subscale indicating worse executive function. Increasing ln-Pb was also associated with worse OM (parent-rated: 0.7 (-0.6, 1.9)) and working memory (parent-rated: 0.9 (-0.5, 2.3)) subscale performance. There was no evidence of interaction. Conclusion: Our findings suggest that prenatal exposure to common metal mixtures may adversely affect executive function in childhood. In our study, Se was a key contributor to the associations, highlighting the importance of evaluating health effects of multiple metals including essential elements.

### **003.04.13. Assessing the Relation of Chemical and Non-Chemical Stressors with Risk-Taking Behavior among Adolescents Living near the New Bedford Harbor Superfund Site**

Veronica Vieira

*Veronica M. Vieira<sup>1</sup>, Jonathan Levy<sup>2</sup>, M. Patricia Fabian<sup>2</sup>, Susan A. Korrick<sup>3</sup>*

**Abstract:** Background: Adolescent risk-taking is multifactorial and influenced by sociodemographics and peer behavior. In addition, evidence suggests that early life exposure to neurotoxicants such as polychlorinated biphenyls (PCBs) and lead (Pb) can impede development of the prefrontal cortex and may contribute to risk-taking. This is of concern among communities that have been exposed to multiple chemical and non-chemical stressors. Methods: We investigated the relation of mixtures of prenatal chemical exposures and non-chemical stressors with adolescent self-reported sensation seeking and anger control in the New Bedford Cohort, a study of children born 1993-1998 near the New Bedford Harbor Superfund site. Outcomes were measured using the Behavior Assessment System for Children, 2nd ed., a standardized behavioral rating scale (n=476). We constructed multi-dimensional smooths using generalized additive models (GAMs) to explore relationships among combinations of stressors, with further adjustment for child's age at exam, sex, maternal education and marital status. Results: Cord blood Pb and PCB measures, maternal IQ and age at birth were included in GAMs. Children of younger mothers with lower IQ who were also exposed prenatally to higher Pb and PCBs had poorer anger control ( $p < 0.001$ ). This Pb/PCB pattern was not apparent for children of older mothers with higher IQs. Sensation seeking behavior was also associated with a mixture of Pb, PCBs, and maternal IQ ( $p = 0.041$ ), but with no differences by maternal age. Conclusion: Analyses suggest that prenatal chemical exposures and maternal characteristics may interact to contribute to increased risk-taking behaviors in adolescence. This work also illustrates the utility of GAMs for visualizing mixtures and non-linear relationships among risk factors, as the importance of both chemical and non-chemical stressors would not likely have been discovered using more traditional epidemiologic models. *2. Child and Adolescent Psychiatry, Hassenfeld Children's Hospital at NYU Langone, New York, NY, United States.*

Abstract: Most research on childhood environmental contributors to early puberty has examined toxins singly in a limited window, often using parametric, regression-based modeling. A realistic assessment of health effects must incorporate multiple exposures over a longer period and allow for interaction between factors. Tree-based analytic methods recursively split the complete study population into multiple subsets based on exposure(s) that most strongly predict the outcome. Tracing down the branches created by these exposure-based splits yields exposure combinations associated with the outcome of interest, allowing for the simultaneous consideration of multiple exposures while allowing for modification by demographics and/or interaction between exposures. The goal of this analysis was to apply tree-based methods to data from a study of 192 nine-year-old New York City girls to identify exposures associated with pubertal development. Using data and biological samples collected during in-person interviews, we derived over 50 exposure variables including environmental biomarkers, ambient air pollutants, dietary components, and demographics. Pediatrician-assessed pubertal development was based on Tanner staging and recorded separately for breast and pubic hair, with stages 2 through 5 indicating puberty. We constructed multiple classification trees for pubertal outcomes utilizing all of the available environmental exposure metrics. For breast development, branches of the trees identified race-specific protective effects of five urine- or dietary-based measures of phytoestrogens. For example, breast development was less likely among Black girls with higher urinary concentrations of daidzein and among white/Latina girls with higher levels of urinary concentrations of genistein. These results illustrate how data-driven approaches can uncover environmental contributors to disease that may be masked when interactions or modification by demographics are not explicitly considered.

### **003.04.15. Multi-Metal Exposure and Children's Cognitive Development in Montevideo, Uruguay**

Julia Ravenscroft

*Julia Ravenscroft<sup>1</sup>, Gabriel Barg<sup>2</sup>, Elena I. Queirolo<sup>2</sup>, Marie Vahter<sup>4</sup>, Nelly Mañay<sup>3</sup>, Katarzyna Kordas<sup>1</sup>*

*3. Faculty of Chemistry, University of the Republic of Uruguay, Montevideo, Uruguay.*

*4. Karolinska Institutet, Stockholm, Sweden.*

**Abstract:** There is growing evidence that co-exposure to multiple metals can result in increased neurotoxicity compared to single metal exposures. As co-exposure to multiple metals at fairly low levels is a likely scenario for most children, understanding the effects of metal mixtures on neurodevelopment is important. In a cross sectional study we examined the association between a metal mixture comprised of urinary concentrations of lead (Pb), arsenic (As), molybdenum (Mo), as well as hair concentrations of cadmium (Cd) and Manganese (Mn) with a measure of overall cognitive ability, the Woodcock-Muñoz General Intellectual Ability score (WMGIA,  $M \pm SD$ :  $473.7 \pm 11.8$ ). First-grade children (aged 6-8 yrs) from 11 private elementary schools within the city of Montevideo, Uruguay participated between July 2009 and August 2013. Metal concentrations were measured in first void urine samples via inductively coupled plasma mass spectrometry (ICP-MS). Metal concentrations were adjusted for specific gravity to compensate for variation in urine dilution, then log<sub>2</sub>-transformed. Rinsed, dried, and acid-digested hair samples were analyzed using ICP-MS and also log<sub>2</sub>-transformed. A weighted quantile sum regression (WQSR) approach was used in a complete case analysis ( $n=264$ ) to calculate a multi-metal index across 100 bootstrapped samples in a training data set (40% of observations). The association of the index with WMGIA was then tested (covariate-adjusted) in the validation set (60% of observations). Each 25% increase in the multi-metal index was associated with a 3.37 reduction in WMGIA score (0.8 % change from mean), indicating a modest but significant mixture effect. Each metal contributed differentially to the index, with Cd (42% overall) and Mo (25% overall) dominating. Understanding the effects of metal mixtures is critical for progressing the field of environmental health and protecting children's neurodevelopment. WQSR provides information that supplements single-metal models.

### **O03.04.16. Neighborhood Disadvantage and Self-Reported Health**

Timothy Wade

*Timothy Wade<sup>1</sup>, Reagan Converse<sup>1</sup>, Shannon Griffin<sup>1</sup>, Jennifer Styles<sup>1</sup>, Andrey Egorov<sup>1</sup>*

*1. EPA, Chapel Hill, NC, United States.*

**Abstract:** Self-reported health is a strong predictor of mortality. Residence in a disadvantaged neighborhood can adversely affect conditions such as safety, access to the natural environment, quality of housing, and stress which also influence health. We evaluated the association between self-reported health and neighborhood in a cross-sectional study in central North Carolina. Participants completed a clinic visit and a questionnaire. The questionnaire addressed self-reported health (Excellent, Good, Fair and Poor), medical history and demographics. Participants provided saliva and serum samples to test for a set of health biomarkers. Neighborhood information was obtained from the US Census for the census-block group associated with each participant's residence. A neighborhood disadvantage index (NDI) was created based on: % without high school degree, % unemployed, % below poverty, % vacant properties, % residences with > 1.5 occupants per room, and % on food assistance. Z-scores were calculated for each of the log-transformed characteristics, summed and categorized in quartiles (1=least disadvantaged; 4=most disadvantaged). Ordinal logistic regression was used to model self-reported health in relation to NDI. Individual measures of age, race, body-mass index, smoking, alcohol, and education were considered as covariates with final models selected by minimizing the AIC. There were 223 participants from 143 block-groups. There was a consistent trend across NDI quartiles with increasing disadvantage associated with worse self-reported health (aOR=1.28, 95% CI =1.02-1.63). Those in the highest NDI (most disadvantaged) were over 2 times (aOR=2.15, 95% CI=1.03-4.56) more likely to report worse health as those with the lowest NDI. These findings provide additional support for the important contextual effect of neighborhood on health. In future analysis, we will evaluate biomarkers which may mediate this association. This abstract does not represent EPA policy.

### **003.04.17. Use of Geocoding to Understand Variation in Neighborhood Socioeconomic Status in a Nationwide Occupational Cohort across Time, Space and Demographic Characteristics**

Gabriela Bustamante Callejas

*Gabriela Bustamante Callejas<sup>1</sup>, Theresa Osypuk<sup>2</sup>, Cari Kitahara<sup>3</sup>, Richard Maclehose<sup>2</sup>, Marizen Ramirez<sup>1</sup>, Martha Linet<sup>3</sup>, Bruce Alexander<sup>1</sup>*

*1. Environmental Health Sciences, University of Minnesota, Falcon Heights, MN, United States.*

*2. Epidemiology, University of Minnesota, Minneapolis, MN, United States.*

*3. NIH/NCI, Rockville, MD, United States.*

Abstract: Geocoding has been used in environmental epidemiology to understand geographically patterned exposures but has not been widely applied in occupational studies. We present the feasibility of geocoding a nationwide occupational cohort, the US Radiologic Technologists Study (USRT, N=146,021) to: (1) evaluate geocoding across time, (2) test precision of geocoding by rural (vs. urban) status and by neighborhood socioeconomic status (nSES), and (3) explore nSES distribution by some cohort demographic factors. We created a standardized nSES index, based on validated methods, for each census block-group in the US, at 3 time points, using 6 items from the U.S. Census (1990, 2000) and American Community Survey (2010): regionally-adjusted median household income and median housing value, % households with interest/income, % adults who completed high school, % adults who completed college, and % employed persons in managerial occupations. To link nSES to the cohort, we geocoded respondent addresses in 1992, 2003, 2010, to block-group of residence. Over 99% of addresses were geocoded; 76 to 86% were mapped to an address-specific block-group, while the rest were geocoded to a block-group of the zipcode centroid. Urban (vs. rural) addresses and those in the highest (vs. lowest) nSES quintile were more likely to be geocoded to an address-specific block-group (OR=4.6; 95%CI=4.5-4.7 and OR=6.4; 95%CI=6.1-6.7, respectively for 1992 addresses). Results of linear regression show higher nSES in 1990 was associated with USRT participants of female gender ( $\beta=0.22$ ; 95%CI=0.20, 0.23), older age ( $\beta=0.003$ ; 95%CI=0.002, 0.003), white race ( $\beta=0.37$ ; 95%CI=0.35, 0.38) and more recent age-adjusted certification year ( $\beta= -0.018$ ; 95%CI= -0.016, -0.019). Similar results were obtained for other years. This analysis indicates geocoding can describe neighborhood characteristics within the USRT which may be related to diseases linked to occupational exposures like cancer and cardiovascular disease.

### **003.04.18. Combined Prenatal Environmental and Social Exposures and Associations with Weight and Adiposity at Birth in the Denver Healthy Start Birth Cohort**

Sheena Martenies

*Sheena E. Martenies<sup>1</sup>, William Allshouse<sup>2</sup>, Anne Starling<sup>3</sup>, Brandy M. Ringham<sup>5</sup>, Deborah H. Glueck<sup>5</sup>, John L. Adgate<sup>4</sup>, Dana Dabelea<sup>3</sup>, Sheryl Magzamen<sup>1</sup>*

- 4. Environmental and Occupational Health, University of Colorado Denver, Aurora, CO, United States.*
- 5. Biostatistics, Colorado School of Public Health, Aurora, CO, United States.*

**Abstract:** Background Neighborhood environmental and social exposures are known risk factors for adverse childhood health outcomes, but the effects of combined exposures in these domains are not fully understood, particularly for body mass or adiposity at birth. We assessed single- and multi-domain exposures for participants in the Healthy Start study, a longitudinal cohort of 1410 mother-child pairs in Metropolitan Denver, CO, and tested associations with body measures at birth. Methods Environmental (ENV) exposures including ambient air quality, toxic release data, and built environment characteristics, e.g., impervious surface %; social (SOC) exposures including demographics, population vulnerability, and crime; and combined exposures (CE) averaged over a 5-year period were assessed at census tracts using a weighted index (scaled from 0-100) following CalEnviroScreen 3.0 and assigned using address at enrollment. Offspring body mass, fat mass, and fat mass percent (adiposity) were obtained by air displacement plethysmography within three days of birth. In separate linear regression models we tested associations between body mass or adiposity outcomes with ENV, SOC or CE as the main predictors. Results Exposure and outcome data were available for 993 (74%) participants. Median (range) ENV, SOC and CE values were 65.8 (53.9-82.5), 62.1 (7.3-98.2), and 48.9 (5.5-88.7), respectively. No significant associations were found with adiposity. A 10-point increase in SOC and CE was associated with a 22g (95%CI: 8-35g) and 24g (95%CI: 8-40g) decrease in body mass at birth, respectively. After controlling for maternal and infant covariates, associations for SOC and CE were attenuated and no longer significant at  $\alpha=0.05$ . Conclusions Combined exposures during pregnancy may be associated with lower body mass at birth. Future research will explore components of the indices and whether cumulative exposures or exposures during specific gestational periods are associated with offspring mass outcomes.

**Abstract:** This study explores the relationship between socioeconomic position (SEP) across the life course and circulating C-reactive protein (CRP), a marker of systemic inflammation, in 6 European cohort studies participating in the Lifepath project. To evaluate the importance of the context and cohort specificities, analyses were performed separately for each cohort and combined in a random effect meta-analysis of up to 23 008 participants (55.7% of men). First, we estimated the association between measures of three time point SEP (father's occupation as early life SEP, educational attainment as young adulthood, participant's last occupation as adulthood) and adulthood CRP, adjusting for health behaviours (smoking, alcohol consumption, sedentary) and body mass index (BMI). Second, to mimic life course experiences, we analysed the relationship between father's occupation and CRP, sequentially adjusting for subsequent measures of SEP in young adulthood and adulthood on a subset of 4 cohort studies (N=13 078). We also investigated whether health behaviours or BMI affected the association between life course SEP and inflammation. Our findings reveal a consistent inverse association between SEP and CRP across cohorts, where participants with lower SEP had higher levels of CRP. In most cohorts, and in the meta-analysis, educational attainment was the SEP indicator most strongly related to inflammation where low educational attainment was associated with higher log-transformed levels of CRP ( $\beta=0.30$ , 95% CI 0.22-0.38). Our findings also suggest that the higher CRP among the low educational attainment group was only partly attributable to BMI ( $\beta=0.19$ , 95% CI 0.11-0.28) and smoking ( $\beta=0.27$ , 95% CI 0.19-0.35). From this work, we conclude that socioeconomic circumstances across the life course are associated with higher levels of inflammation in adulthood, suggesting that social-to-biological processes are at play, beyond the impact of health behaviours and BMI.

### **O03.04.20. Modification of Asthma Clinical Trial Results by Environmental and Socioeconomic Exposures**

Jane Clougherty

Abstract: Randomized clinical trials (RCTs), generally considered the gold standard of evidence in medical research, randomize and balance treatment and control arms, thereby maximizing internal validity, and reducing between-group biases resulting from variation in individual patient characteristics. This assumption may well hold true for the population accurately represented by the trial cohort, however RCTs do not generally control for environmental exposures and socioeconomic position (SEP), which may impact clinical outcomes, treatment response, and generalizability. To assess whether variation in SEP and environmental exposures across an asthma RCT cohort modify treatment response, we developed Geographic Information Systems (GIS)-based metrics to characterize residential exposures for the 221 children in the Step Up Yellow Zone Inhaled Corticosteroids to Prevent Exacerbations (STICS) study. On average, across the cohort, there was no significant effect of 5x increased corticosterone dose on a range of outcomes (e.g., exacerbation rate, albuterol use). We found, however, that higher roadway densities conferred a greater number of exacerbation events and unscheduled medical visits. Further, children in areas of greater poverty and home vacancy had significantly shorter times to first corticosteroid use. We are now examining near-residence roadway densities, poverty rates, and housing vacancy rates on variation in observed treatment efficacy. Using spatial analysis and GIS to understand the lived context of RCT participants - better accounting for socioeconomic and environmental factors - may help to improve the interpretation of RCT results, to better identify subpopulations for whom an intervention may be most effective, and to inform on the generalizability of RCT results.

## S03.04A. Chemical Policy in the 21st Century: Comparing Canadian, US, European and Asian Approaches

### **S03.04.01. The Perils and Promise of the 2016 Lautenberg Chemical Safety Act: A Critical Appraisal of the U.S. Experience**

Tracey Woodruff

*Tracey Woodruff<sup>2</sup>, Patricia D. Koman<sup>1</sup>, Juleen Lam<sup>2</sup>*

*1. Environmental Health Sciences, University of Michigan School of Public Health, Ann Arbor, MI, United States.*

*2. OB/Gyn and Reproductive Sciences, University of California San Francisco, San Francisco, CA, United States.*

Abstract: In the U.S., people are exposed to multiple industrial chemicals, many of them known to cause adverse health effects (e.g. asbestos, methylene chloride). Further, 8,700 high production volume chemicals are largely untested for health effects. Many chemicals are not tested or regulated because of flaws in the law that governs chemicals in the U.S.-the 1976 Toxic Substances Control Act. In 2016, amendments called the Frank Lautenberg Chemical Safety for the 21st Century Act (Lautenberg TSCA) were finalized to address these gaps and directed the US Environmental Protection Agency (USEPA) to evaluate chemicals under enforceable deadlines against risk-based safety standards that account for susceptible subpopulations and with new powers to compel manufacturers to test products for safety. However, many scientific decisions are left to USEPA during implementation, including how to evaluate human and animal scientific evidence, define susceptibility and aggregate risk, incorporate new science into risk assessment, define conditions of use, and determine what constitutes an unreasonable risk. Actions by USEPA may preempt individual states from taking any further action on regulated chemicals. Implementation can either lead to public health protections or worsening of the deficits that have hampered U.S. chemical policy for the past 40 years. Effective public health protection requires strong implementation of Lautenberg TSCA, in which USEPA evaluates, assesses and limits exposures to multitudes of harmful chemicals, and corporations provide adequate evidence to evaluate hazards. This presentation will briefly introduce data needs and ways to improve the scientific basis, transparency and protection of vulnerable populations in chemical assessments under the new law. The role for epidemiologic studies and biomonitoring data from pregnant women will be featured. We recommend principles geared towards ensuring U.S. chemical policy that is truly public health protective.

## **S03.04.02. REACH Chemical Policy at 10 Years: A European Perspective on Lessons Learned**

Vito Buonsante

*Genon Jensen<sup>1</sup>, Vito Buonsante<sup>2</sup>*

*1. Health and Environmental Alliance , Brussels, Belgium.*

*2. McMaster University, Toronto, Canada.*

Abstract: Effective chemical policy which accurately assesses potential chemical hazards to human health and the environment and appropriately restricts risky chemicals is vital because health impacts from industrial chemical exposures are preventable. Primary prevention through policy could significantly improve public health and reduce health costs, and the EU chemicals safety legislation REACH is a key framework. The presentation will briefly discuss major issues regarding epidemiologic and exposure data needs, improving risk assessments, and challenges to achieving public health protections based on 10 years of REACH implementation in the European Union and the Health and Environment Alliance's (HEAL) experience of European policy approaches to gathering data and assessing risk from environmental chemicals. HEAL's technical, scientific and policy work has focused within the European Chemical Agency (ECHA) as an official health stakeholder and active participation in several ECHA committees, including the ED Expert group, which focuses on evaluating substances with EDC properties, providing informal, non-binding scientific advice on questions related to the identification of ED chemicals. Our key objectives in providing the health evidence and public health advocacy: 1) EU and international chemicals policies take a precautionary approach by prioritising the phase out of hazardous chemicals and promotion of safer alternatives; particularly for endocrine disruptors, and 2) Risk assessments are based on assessing harm to vulnerable groups; and incorporate chemicals mixtures and multiple exposures HEAL and its scientific experts provide health expertise for chemicals that are under assessment for being placed on REACH's candidate list, meaning that they would be subject to future restrictions, including high profile chemicals and test cases such as glyphosate, PFOAs, BPA, phthalates.

### **S03.04.03. Canadian Chemical Management Plan's Successes and New Directions**

Miriam Diamond

*Miriam L. Diamond<sup>1</sup>*

*1. Department of Earth Sciences, University of Toronto, Toronto, ON, Canada.*

Abstract: The Canadian Environmental Protection Act (CEPA) was proclaimed in 1999 as overarching legislation guiding pollution prevention and chemical management. Within CEPA, the Chemical Management Plan (CMP) was implemented to undertake chemical adjudication and management. In CEPA, risk-based toxic substances management is based on: (1) the greatest potential for human exposure and (2) Persistence, Bioaccumulation and inherent Toxicity characterizations. With 23,000 substances on the Domestic Substances List, 4,300 substances were identified for human health and ecological health assessments between 2011 and 2020 with the remainder designated as low priority. Also screened annually are 400 to 500 New Substances Notifications. The main data gaps challenging the human health assessments have been in exposure and toxicity. Biomonitoring under the Canadian Health Measures Survey and specific epidemiological studies have filled some gaps in exposure data. Without such data (and even when this is known), forward dosimetry has been based on substance usage data mostly provided by industries and pathway modelling. Much interest in CMP has come for using "New Approach Methodologies" or NAMs that include in silico, in chemico and in vitro toxicity assays. A framework is being developed for using "Read across" methods for approximating the toxicity of substances with limited data. The success of Canada's Chemical Management Plan was the initial screening categorization process of the 23,000+ substances and the nearly completed risk assessments of 4,300 substances. Assessors have incorporated new methods as the assessment process is not overly prescribed and hence flexible. CEPA will be updated shortly with the likely consideration of vulnerable populations, occupational exposure, cumulative effects, and the need to deal with chemical mixtures. Challenges remain regarding assessment over the life cycle of a chemical and how to best maintain a flexible approach that allows for innovation.

#### **S03.04.04. Human Biomonitoring as a Tool to Support Chemicals Regulation**

Catherine Ganzleben

*Catherine Ganzleben<sup>1</sup>*

*1. European Environment Agency, Copenhagen, Denmark.*

Abstract: The European Human Biomonitoring Initiative, HBM4EU, represents a joint effort of 26 countries and the European Commission, co-funded by Horizon 2020. The main aim of the initiative is to coordinate and advance human biomonitoring in Europe. HBM4EU is providing better evidence of the actual exposure of citizens to chemicals and the possible health effects to support policy making. The project involves collaboration between several Commission services, EU agencies, national representatives, stakeholders and scientists, demonstrating how research funding can build bridges between the research and policy worlds. HBM4EU kicked off in January 2017 and will run for 5 years until December 2021. HBM4EU will contribute to the overarching goal of ensuring that EU chemical policies minimise the adverse effects of chemicals on human health. In this presentation, accomplishments to date and future research goals of the European Human Biomonitoring Initiative (HBM4EU) will be presented. This will include reflections on opportunities in EU chemical risk assessment and risk management for using HBM results.

### **S03.04.05. New Chemical Safety Policy in Korea to Achieve Public Health Protection: Experience of K-REACH**

Jong Han Leem

*Jong Han Leem*<sup>1</sup>

*1. Dept of Occupational and Environmental Medicine, Inha University Hospital, Incheon, Korea (the Democratic People's Republic of).*

Abstract: The "Law on the Registration and Evaluation of Chemical Substances," in Korea (K-REACH) requires all new chemical substances and existing chemical substances manufactured, imported and sold for more than 1 ton per year to be registered at the Environment Protection Agency or the local environment agency. By law imports and sales volume should be reported, and hazard and risk should be examined and evaluated. It was enacted on May 22, 2013, with the need to strengthen the management of chemical products in the wake of the death of the humidifier disinfectant in 2011, and has been in effect since January 2015. K-REACH has been evaluated as being the most similar to EU REACH in Asia. On August 16, 2017, Korean government submitted a bill, named as Consumer Chemical Products and Biocides Safety Control Act to the National Assembly. This will come into effect on January 1, 2019. Similar to the EU Biocidal Products Regulation, Korean Biocides Bill introduces a market pre-approval system for active substances and biocidal products, by applying "No Safety, No Market" principle. It strengthens risk communication, through disclosing information related to the entire component and risks of the biocides. The K-REACH, Chemical Control Act, and Chemical Products and Biocides Safety Control Act which are regarded as advanced systems, still has many difficulties. Especially, it is the industry's objection that the industrial sector has the problem that the scope of reporting and registration of substances is too wide in K-REACH, and Biocides Safety Control Act. The industrial sector complained that this new acts give too heavy burden to the industrial sector. But environmental NGO and civil organizations protested against too many exception and exemption in this acts and insisted that no matter how small the distribution, the toxic substances, such as substances of very high concern (SVHCs) must be registered and managed.

## S02.02B. Exposure and Risk Assessment of Chemicals in Consumer Articles

### S02.02.06. High-Throughput Exposure Modeling: Conclusions of the ExpoDat Program

Hyeong-Moo Shin

*Hyeong-Moo Shin<sup>1</sup>*

*1. University of Texas, Arlington, Arlington, TX, United States.*

**Abstract:** Background: While a growing number of chemicals have been introduced into commerce over the past several decades, there is a dearth of exposure and toxicity information available to assess potential harmful effects of these chemicals to humans. The immediate needs for rapid, or high-throughput (HT), exposure assessment were identified from ExpoDat, a program developed as part of the American Chemistry Council's Long-Range Research Initiative. Objective: To discuss limitations and potential improvements in HT exposure modeling of chemical exposure from the ExpoDat program efforts. Methods: As part of ExpoDat, 180 organic chemicals that had at least one ToxCast in vitro assay hit were selected to identify chemicals for potential health concerns. For comparison with the ToxCast assay, a series of models were applied to estimate exposure in a HT manner. For each chemical and use scenario, exposure models were used to calculate a chemical intake fraction, or a product intake fraction, accounting for chemical properties and the exposed population. These intake fractions were then combined with use scenario-specific estimates of chemical quantity to calculate daily intake rates (iR). The iRs were compared with those inferred from biomonitoring data in the National Health and Nutrition Examination Survey (NHANES). Results: Overall, iRs were overestimated. For compounds with multiple exposure pathways, estimated maximum iRs were much greater (up to 7 orders of magnitude) than the 95th percentile iRs inferred from biomonitoring data. Lack of data on allocation of chemical quantity to each use scenario and on relevant exposure pathway was identified as a primary source of uncertainty in exposure prediction. Conclusions: The method provides HT estimates of exposure, but identifying relevant pathways and chemical quantity allocation is needed to avoid overly conservative estimates.

## **S02.02.07. Rapid Parameterization of Pathway-Specific Exposure Models**

Kristin Isaacs

*Kristin Isaacs<sup>1</sup>, Katherine Phillips<sup>1</sup>, John Wambaugh<sup>1</sup>, Paul Price<sup>1</sup>, Kathie Dionisio<sup>1</sup>*

*1. US EPA, Research Triangle Park, NC, United States.*

Abstract: Evaluation of biomonitoring data supports the importance of near-field chemical exposure pathways. High throughput (HT) exposure models for consumer products have been developed, but require large amounts of composition, product use, and exposure factor data. EPA's ExpoCast program has worked to obtain and organize publicly-available information for thousands of chemicals to support these models. However, challenges arise in evaluating the applicability of these data to new models, chemicals, products, uses, or populations. Thoughtful model design and data organization can promote reuse of collected information, as can the definition of formal linkages among model inputs and model algorithms describing exposure processes. For example, efficiently modeling chemicals in consumer products is enabled by a fit-for-purpose system of consumer product categories. Categories can be linked to generic exposure scenarios that define indoor fate and transport, route-specific intake, and disposal, and to associated product-specific factors (e.g., use and release patterns), to create a library of fully parameterized algorithms. In this framework, obtaining results for a new chemical does not require de novo parameterization, only knowledge of its concentration in products. In addition, defining generic chemicals within categories (e.g., via Latin hypercube sampling of physicochemical space for chemicals in products) will allow for rapid read-across of exposure results. While near-field models may adequately capture chemical-to-chemical variability in population median exposure, new HT ambient exposure (e.g., associated with industrial releases) or occupational exposure models will be required to address populations having outlier exposure patterns. Obtaining and organizing available data and algorithms for these populations is a current focus in ExpoCast. This abstract may not reflect U.S. EPA policy.

## S02.02.08. Modeling on Many Scales - Multiscale Modeling of Exposure to Chemicals in Products

Olivier Jolliet

*Olivier Jolliet<sup>1</sup>, Cedric Wannaz<sup>1</sup>, Lei Huang<sup>1</sup>, Peter Fantke<sup>2</sup>*

*1. Environmental health sciences, School of Public Health, University of Michigan, Ann Arbor, MI, United States.*

*2. Quantitative Sustainability Assessment Division, Department of Management Engineering, Technical University of Denmark, Lyngby, Denmark.*

Abstract: Informing decision about chemical alternatives and related exposure to chemicals in consumer products necessitate to cover both far and near-field exposure over a range of scales and receptor populations. Building on USEtox, we present a suite of models covering a) near-field direct exposure of consumers to chemicals in products and in indoor air, and b) the far-field environmental and human exposure associated with localized chemical releases. In addition to the continent specific calculations of USEtox, a spatialized adaptation of USEtox is implemented on the multi-scale multimedia Pangea modeling platform, with 120000+ cells from 10km to global scale and using the high resolution global hydrological dataset HydroBASINS. We first apply the model to four chemicals used across Asia, selected to cover a variety of applications, volumes of production and emission, and physico-chemical and environmental fate properties: The anionic surfactant linear alkylbenzene sulphonate (LAS), the antimicrobial triclosan (TCS), the personal care preservative methyl paraben (MeP), and the emollient decamethylcyclopentasiloxane (D5). LAS emission levels and Predicted Environmental Concentrations are two to three orders of magnitude greater than for other substances. We observe a good agreement for TCS in freshwater ( $r=0.82$ , for 253 monitored values covering 12 streams), the substance with most data, whereas the model underestimate MeP sediments concentrations. Intake fraction and spatialized intakes are also determined both for the near field and spatially for environmentally mediated exposure in Australia. The direct indoor exposures are dominant, whereas we observe high spatial variation in intake fractions from 0.68 to 33 ppm for benzene emitted in ambient air, which travels over longer distances, and from 0.006 to 9.5 ppm for formaldehyde that has a more local impact. We finally discuss strengths and weaknesses of each of these complementary tools.

## **S02.02.09. Evaluating Exposure Models**

Jon Arnot

*Jon A. Arnot<sup>1</sup>*

*1. ARC Arnot Research and Consulting Inc., Toronto, ON, Canada.*

Abstract: Exposure models are required to support decision-making in different regulatory assessment contexts (e.g., prioritization, screening-level, and comprehensive). Exposure models provide frameworks for integrating and interpreting exposure information (e.g., emission/use rates, monitoring/biomonitoring data) and for making exposure predictions in the absence of any measured exposure information (e.g., data-poor chemicals for prioritization). Ostensibly, the acceptable magnitude of uncertainty varies depending on the decision and model application contexts. In order to use the models with confidence in chemical assessments there is a requirement to understand: (i) the uncertainty in the model calculations, (ii) the chemical and exposure scenario applicability domains of the models, (iii) the merits and limitations of the models, and (iv) the availability and uncertainty in model input parameters necessary to use the models. Common methods for characterizing model sensitivity and uncertainty will be illustrated with a series of case studies. The case examples show the sensitivity of exposure estimates to chemical use and quantity information, degradation and biotransformation rates, and chemical partitioning properties. Model performance can be quantified by comparing exposure predictions with monitoring and biomonitoring data. In the absence of any measured data (e.g., "data-poor" chemicals) comparisons of different exposure model predictions for the same chemicals and use scenarios can provide insights into the collective uncertainty of the models (e.g., agreement vs. disagreement in exposure estimates) thus providing strategic guidance for research needs to address this uncertainty. Methods for merging available measurements with exposure models (e.g., higher-tiered assessments) to characterize uncertainty and address data gaps in exposure estimation are also demonstrated.

## **S02.02.10. Systematic Empirical Evaluation of Models for Risk Prioritization**

John Wambaugh

Abstract: Prioritizing the potential risk posed to human health by the thousands of chemicals that occur in commerce and the environment requires tools that can estimate exposure from limited information. High-throughput exposure (HTE) models exist to predict exposure via specific pathways. We consider an "exposure pathway" to include a chemical source, interaction with the environment, and a receptor (such as a person). Data for identifying the relevant pathways for chemicals in a high throughput manner are limited. Both expert opinion and conservative assumptions (all chemicals via all pathways) have drawbacks. Here we present a consensus HTE model based on 15 models and databases drawn from a collaboration involving five universities, a research consultancy, and the U.S. EPA. Machine learning predicts the probability that a chemical is associated with four assumed pathways: near-field (residential), dietary, far-field industrial, and far-field pesticide. On a pathway basis, we examine inferred chemical intake rates for the median U.S. population, from the National Health and Nutrition Examination Survey (NHANES). The intake rate for each pathway is either higher (residential, dietary) or lower (pesticidal, industrial) than the average. We use multivariate linear regression to evaluate the predictive ability of each model and database to raise or lower exposure with respect to the pathway averages. We can explain ~70% of the chemical-to-chemical variance in NHANES using the consensus model. We extrapolate model predictions to other chemicals by assuming that chemicals without biomonitoring data will have similar intake rates to those within NHANES. Predictions with quantified confidence intervals may allow risk-based prioritization using the margins between putative bioactive doses and intake rate predictions. This abstract may not reflect U.S. EPA policy

## S03.04C. Effects of Long-Term Exposure to Ambient Air Pollution in the Asia-Pacific Region

### S03.04.11. Long-Term Effects of PM<sub>2.5</sub> on Total Mortality in Seoul, Korea

Hyun-Joo Bae

*Hyun-Joo Bae<sup>1</sup>, Jooyoung Park<sup>1</sup>, Yun-Chul Hong<sup>2</sup>, Youn-Hee Lim<sup>2</sup>*

*1. Korea Environment Institute, Seoul, Korea (the Republic of).*

*2. Seoul National University, SEOUL, Korea (the Republic of).*

**Abstract:** Background: Cohort studies in North America and western Europe have reported increased risk of mortality associated with long-term exposure to fine particles (PM<sub>2.5</sub>), but to date, no such studies have been reported in Korea, where higher levels of exposure are experienced. Objectives: We estimated the association between long-term exposure to PM<sub>2.5</sub> with total mortality in a cohort of Korean. Methods: We conducted a prospective cohort study of 4,171,410 residents 30-year-old or older from 25 areas in Seoul in 2008 and followed-up the cohort until 2015. Average PM<sub>2.5</sub> levels for the 12 or 24 months prior to death were estimated for each cohort location using a Krigging. A Cox proportional hazards regression model was used to estimate hazard ratios (HR) for total mortality after controlling for age, sex, income, year of event, population, area-level socioeconomic indices, and prevalence of chronic obstructive pulmonary disease. Results: The mean level of 12- and 24-month average of PM<sub>2.5</sub> exposure was 22.9 µg/m<sup>3</sup> (S.D. 1.6) and 23.8 µg/m<sup>3</sup> (S.D. 1.3). Of Seoul residents, 228,329 of death occurred (5.47%). Mortality HRs (95% CI) per 1-µg/m<sup>3</sup> increase in PM<sub>2.5</sub> were 1.046 (95% CI, 1.043, 1.048) and 1.056 (95% CI, 1.051, 1.059) for 12- and 24-month exposures, respectively. Conclusions: Long-term exposure to PM<sub>2.5</sub> was associated with total mortality in Seoul, Korea.

### **S03.04.12. Long-Term Exposure to Air Pollution and All-Cause and Cause-Specific Mortality in Okayama, Japan**

Takashi Yorifuji

*Takashi Yorifuji<sup>1</sup>, Saori Kashima<sup>2</sup>, Hiroyuki Doi<sup>3</sup>*

*1. Department of Human Ecology, Graduate School of Environmental and Life Science, Okayama University, Okayama, Japan.*

*2. Department of Public Health and Health Policy, Graduate School of Biomedical and Health Sciences, Hiroshima University, Hiroshima, Japan.*

*3. Department of Epidemiology, Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama University, Okayama, Japan.*

Abstract: A number of studies have linked long-term exposure to air pollution, especially particulate matter with aerodynamic diameter  $< 2.5 \mu\text{m}$  (PM<sub>2.5</sub>), with cardiovascular disease and lung cancer mortality. But, most of the studies were conducted in the United States and Europe. Although literature is being accumulated, evidence is still limited in Asian countries. We therefore evaluated the association of long-term exposure to air pollution, especially PM<sub>2.5</sub>, and all-cause and cause-specific mortality among a cohort study in Okayama, Japan. We followed up a cohort of 76,591 participants who were enrolled in regular health checkups held in Okayama City in 2006 and 2007. After obtaining the participants' addresses at the census level, we assigned modeled PM<sub>2.5</sub> data provided from the Atmospheric Composition Analysis Group to the participants. We evaluated mortality outcomes through record linkage to the vital statistics from the Ministry of Health, Labour, and Welfare in Japan. We focused on all-cause and cause-specific mortality such as cardiovascular disease and lung cancer as main health outcomes. We used Cox proportional hazard models adjusting for individual-level potential confounders and area-level socioeconomic status in the model. We present the findings in the symposium.

### **S03.04.13. Long-Term Exposure to PM2.5 Components and Cardiovascular Mortality in a Chinese Cohort**

Haidong Kan

*Haidong Kan<sup>1</sup>*

*1. Fudan University, Shanghai, China.*

Abstract: Few prior cohort studies exist in developing countries examining the association of ambient fine particulate matter (PM2.5) components with mortality. We examined the association of PM2.5 components with cardiovascular mortality in a prospective cohort study of 61,768 participants in 161 Chinese cities. Baseline data were obtained during 2010-2010. The participants were followed up from 2011 to 2015. Annual average concentrations of PM2.5 components between 2011 and 2015, including elemental carbon (EC), organic carbon (OC), sulphate (SO4<sup>2-</sup>), nitrate (NO3<sup>-</sup>) and ammonium (NH4<sup>+</sup>), were estimated by the Community Multiscale Air Quality (CMAQ) model. As the results, we found significant associations between PM2.5 and mortality from cardiovascular diseases; each 10 µg/m<sup>3</sup> PM2.5 was associated with a 2.8% (95CI: 0.7%, 4.8%), 3.2% (95CI: -0.3%, 6.8%) and 4.6% (95CI: 1.8%, 7.5%) increased risk of cardiovascular, coronary heart disease and stroke mortality, respectively. An interquartile range (IQR) increase of EC, OC, SO4<sup>2-</sup>, NO3<sup>-</sup> and NH4<sup>+</sup> were associated with 17.7% (95CI: 7.8%, 28.5%), 16.6% (95CI: 6.1%, 28.2%), 3.8% (95CI: -6.2%,14.8%), 26.7% (95CI: 10.6%,45.2%), and 17.8% (95CI: 4.3%, 33.0%) increase of cardiovascular mortality, respectively. Conclusively, these data contribute to the scientific literature on long-term effects of particulate air pollution for high exposure settings typical in developing countries.

### **S03.04.14. Long-Term Exposure to Low Level Air Pollution in Sydney and Mortality and Hospital Admission Using the '45 and Up' Cohort: Methodological Challenges**

Bin Jalaludin

*Geoffrey Morgan<sup>1</sup>, Margaret Rolfe<sup>3</sup>, Farhad Salimi<sup>1</sup>, Ivan Hanigan<sup>1</sup>, Luke Knibbs<sup>4</sup>, Martin Cope<sup>5</sup>, Jane Heyworth<sup>6</sup>, Bin Jalaludin<sup>2</sup>*

- 1. School of Public Health, University of Sydney, Sydney, NSW, Australia.*

- 4. University of Queensland, Brisbane, QLD, Australia.*
- 5. CSIRO, Melbourne, VIC, Australia.*
- 6. University of Western Australia, Perth, WA, Australia.*

**Abstract:** We used the '45 and Up' cohort study of older (45+ years) residents of New South Wales, Australia, to investigate the health effects of long term air pollution exposure. Individual level data was collected on 267,153 subjects via baseline questionnaire mostly completed in 2008 and these data were linked to routinely collected death registrations data (up to 2015) and hospital admissions data (up to 2014) via personal identifiers (including age, sex, residential address). Neighbourhood level socio-economic status data was linked to study subjects residential address. Subjects residential address was used to estimate annual average NO<sub>2</sub> exposure using a satellite based land use regression model for 2007 for all study subjects, while Chemical Transport Model data blended with fixed site monitor data for 2010/11 was used to estimate annual average PM<sub>2.5</sub> exposure for subjects in the Sydney metropolitan area. We implemented Cox proportional hazards models to assess the associations between air pollution exposure and all-cause mortality, and respiratory hospital admissions while adjusting for individual level socio-demographic and behavioral factors, as well as area-level factors. Annual average PM<sub>2.5</sub> and NO<sub>2</sub> exposure was 4.5 µg/m<sup>3</sup> and 17.5 µg/m<sup>3</sup> respectively. Covariate adjusted models found that mortality and respiratory hospital admissions were associated with PM<sub>2.5</sub> and NO<sub>2</sub> (mortality Hazard Ratios (HR)=1.06 (95% CI: 1.00-1.11), asthma admissions HR=1.08 (95% CI: 0.89 - 1.30), bronchitis admissions HR=1.32 (95%CI: 0.96 - 1.80) per 1 µg/m<sup>3</sup> increase in PM<sub>2.5</sub> respectively). Increasing model complexity generally reduced the magnitude of the HR point estimates and the strength of the associations but may have resulted in over control for covariate effects. Even at the relatively low level long term air pollution exposures generally seen in Sydney, and with limited follow up, air pollution exposure within our cohort had a detrimental effect on mortality and hospitalisation.

### **S03.04.15. Lessons Learned from the ESCAPE Project**

Bert Brunekreef

*Bert Brunekreef<sup>1</sup>*

*1. utrecht university, Utrecht, Netherlands.*

Abstract: The European study of cohorts for air pollution effects (ESCAPE) was a large-scale effort including data from about 35 different cohort studies conducted in Europe. The cohorts included birth cohorts, respiratory morbidity cohorts, cardiovascular morbidity cohorts, and cohorts focused on lung cancer and mortality. Measurement campaigns were carried out for nitrogen oxides and airborne particulate matter in all areas where study participants lived. The measurement data were then used to develop land-use regression models explaining the spatial variability of the air pollution concentrations. These models were subsequently used to estimate air pollution concentrations at the home address of the study participants. A variety of outcomes were studied. For most endpoints, data were analysed within the individual cohorts and results combined by meta analyses. Many lessons were learned from the escape project, especially related to the importance of strict adherence to protocols for air pollution measurements, exposure modelling, and epidemiological data analyses within the individual cohorts. A pooling effort in the analyses on birthweight showed a clear gain in efficiency over doing just a meta-analysis. In a follow-up study the emphasis is now on pooling individual data from participating cohorts. The escape project also served as a training ground for many young researchers working in the different participating study teams. Authorships were widely shared among the study teams and first authorships were often allocated to young researchers such as PhD students and postdocs. This strategy contributed to enthusiasm and commitment among the study teams without which the study could not have been carried out as it was.

S03.04D. Exposure to Pesticides and Heavy Metals in the African Context: Electronic Waste, Artisanal and Small-Scale Mining, and Indoor Residual Spraying

**S03.04.16. Neurodevelopmental Outcomes of Children Exposed to Lead in Selected Locations of Kabwe District in Zambia**

Nosiku Munyinda

*Nosiku S. Munyinda<sup>1</sup>*

*1. Environmental Health, School of Public Health, University of Zambia, Lusaka, Lusaka, Zambia.*

Abstract: Kabwe, the provincial headquarters of the Central Province of Zambia has been the principal producer of lead (Pb) and Zinc (Zn) since the early 1900's. The consequent pollution arising from unregulated mining and smelting of Pb, Zn and Cadmium (Cd) and the production of sulfuric acid is massive. The intense environmental contamination has resulted in Blood Lead Levels (BLLs) in children between 60 and 120 µg/dL. A 2006 study concluded that there could be 650 cases in Kabwe and the surrounding communities with BLL > 65 µg/dL, levels that could induce sub-acute toxicological effects. These high-Pb soils and BLL have resulted in Kabwe being named among the top ten most polluted places in the world. Lead is known to negatively affect neurological development, but to date there is no known study that explores the differential exposure levels and pathways over time during the most crucial periods of neurological development in pregnancy and the first two years after birth in Africa. For the babies, a physical examination including a new-born exam, height, weight, head circumference was done. These were analyzed taking into account potential confounders related to baseline health status, socio-economic status and other individual characteristics of the mothers. The Ages and Stages Questionnaire (ASQ), extensively used to assess the development of infants, was used for the Neurodevelopmental Assessment. The results revealed median BLLs of 35.1mg/dl (IQR 0 - 381.6) for all the areas. Significant associations were found between proximity to the mine and the BLLs. Mean scores for communication, gross motor, fine motor, problem solving and personal social domains were 44, 44, 40, 37 and 38 across all the areas. There were significant differences across the areas with lower scores below the cutoff points recorded in areas which recorded higher Blood Lead Levels in the children.

### **S03.04.17. Mercury Exposure Biomarkers and Neurologic Measure Differences between Registered and Unregistered ASGM Miners in Ghana**

Nil Basu

*Nil Basu<sup>1</sup>, Benedict Calys-Tagoe<sup>2</sup>, Edith Clarke<sup>3</sup>, Thomas Robins<sup>4</sup>*

- 1. McGill University, Montreal, QC, Canada.*
- 2. University of Ghana, Accra, Ghana.*
- 3. Ghana Health Service, Accra, Ghana.*
- 4. University of Michigan, Ann Arbor, MI, United States.*

Abstract: Workers within artisanal and small-scale gold mining (ASGM) communities are amongst the highest Hg-exposed groups worldwide. While formalization of this sector has been suggested as a means to reduce exposures and improve health and safety, we are unaware of empirical evidence that supports this notion. The objective of this study was to compare mercury exposure profiles and neurologic measures among miners working in licensed versus un-licensed ASGM sites. To achieve this, 404 small-scale miners were recruited in 2014 from 9 mining sites in Tarkwa (Ghana), of which 5 were licensed and 4 were not licensed. Miners were interviewed, performed a range of neurologic tests and surveys, and urine and hair samples were taken for measurements of total Hg content in a subset (n=316). Sociodemographic characteristics of miners from the two groups were relatively similar (33.8 yrs old, 92% male, 29% completed high school, 66% living with a partner). Those currently working in an un-licensed mine have higher mean levels of total Hg in urine (110.7 vs 16.0 ug/L;  $p < 0.001$ ) and hair (4.5 vs. 2.0 ug/g;  $p = 0.09$ ) compared to workers from the licensed mines. A range of other information was collected showing differences between these groups of miners such as work history and injury episodes, and these will be discussed. Neurological measures (e.g., gait, peripheral outcomes) are being finalized. These findings advance our understanding of mercury exposure (and other differences) amongst ASGM workers especially important differences between miners working in a licensed versus and un-licensed site.

### **S03.04.18. Agbogbloshie Electronic Waste Recycling Site: A Case of Focal Environmental Contamination**

Julius Fobil

*Julius Fobil<sup>1</sup>, Nil Basu<sup>2</sup>, Thomas Robins<sup>3</sup>*

*1. Department of Biological, Environmental & Occupational Health Sciences, University of Ghana School of Public Health, Legon, Accra, Ghana.*

*2. Faculty of Agricultural & Environmental Sciences, McGill, Montreal, QC, Canada.*

*3. Department of Environmental Health Sciences, University of Michigan School of Public Health, Ann Arbor, MI, United States.*

"Abstract: Accra, the capital city of Ghana is home to one of Africa's largest informal e-waste dumpsite and scrap yard. This dumpsite, which is popularly called "Sodom & Gomorrah" or "Agbogbloshie" and/or "Old Fadama" in most other instances, started to develop as a settlement in the early 1980s by migrants fleeing communal violence in the parts of the country who found habitation on what used to be a mangrove swamp or waste/wetland. Agbogbloshie is now known for its mixed economy where both formal and informal economic activities co-exist and infamous for raucous noise due to vehicular traffic, itinerant merchant population and clientele, automobiles and large plumes of smoke emanating from e-waste recycling activities under intensely scorching sun. This combination of economic activities from both formal and informal has resulted in extensive localized environmental pollution from heavy metals and persistent organic pollutants in the ambient environmental media - air, soil/sediment and water. In particular, the concentrations copper (Cu) and iron (Fe) has been reported in sampled soil mixtures collected from the sites as 289 mg/kg and 222mg/g for Cu and Fe respectively; while lead (Pb) concentrations ranged from 134 part per million (PPM) to 18,125 PPM. Overall, organics such as polybrominated diphenyl ethers (PBDEs) have been measured in soil samples at Agbogbloshie and the results showed concentrations that ranged from 15.6 to 96.8ng/g. "

### **S03.04.19. Exposure to DDT and Pyrethroid Insecticides and Humoral Response to Vaccines among South African Children from an Area Sprayed for Malaria Control**

Jonathan Chevrier

*Jonathan Chevrier<sup>1</sup>, Brian Ward<sup>1</sup>, Thomas Di Lenardo<sup>1</sup>, Riana Bornman<sup>2</sup>, Muvhulawa Obida<sup>2</sup>, Brenda Eskenazi<sup>3</sup>*

*1. McGill University, Montreal, QC, Canada.*

*2. University of Pretoria, Pretoria, South Africa.*

*3. University of California, Berkeley, Berkeley, CA, United States.*

Abstract: Animals studies strongly suggest that exposure to insecticides such as DDT and pyrethroids inhibit immune response to vaccines. However, few human studies have investigated this question and none have done so in communities where insecticides are used to control malaria as part of Indoor Residual Spraying programs. These communities experience high exposure to insecticides and may be particularly susceptible to their toxic effects due to poverty, malnutrition and poor health. Our objective was thus to evaluate whether prenatal exposure to DDT and pyrethroids was associated with reduced immune response to vaccines at age 3.5 years among South African children participating in the Venda Health Examination of Mothers, Babies and their Environment (VHEMBE) birth cohort study. Between August 2012 and December 2013, we enrolled 752 women when they presented for delivery at Tshilidzini hospital in the city of Thohoyandou. We collected urine and blood samples at delivery for the measurement of pyrethroid metabolites and DDT via gas chromatography-mass spectrometry, respectively. At age 3.5 years, we collected child blood samples and measured measles, tetanus and Haemophilus influenzae b (Hib)-specific 1) antibody titers via enzyme-linked immunosorbent assay (ELISA) and polyfunctional transitional, central and effector memory CD4+ T cells. Initial analyses suggest that each 10-fold increase in maternal DDT serum concentration is associated with a 75% (95%CI=-15, 306) increased risk of measles antibody seronegativity and a 5.2-fold (95%CI=1.5, 17.5) increase in the risk of detecting no transitional memory CD4+ T cells expressing TNF- $\alpha$  and IFN- $\gamma$ . Pyrethroid metabolites cis-DBCA and 3-PBA were primarily associated with reduced measles- and tetanus-specific central memory CD4+ T cells expressing TNF- $\alpha$  and IL-2. Overall, results suggest that exposure to DDT and pyrethroids may inhibit immune response to vaccines among South African children.

## S03.04E. Exposure, Vulnerability, and Capacity Assessment for Health Risks of Climate Change: Measuring and Communicating the Effectiveness of Interventions and Policy Responses

### **S03.04.21. Climate Change and Health Stress Testing**

Kristie Ebi

*Kristie L. Ebi<sup>1</sup>, Katie Hayes<sup>2</sup>, Peter Berry<sup>2</sup>*

*1. Department of Global Health, University of Washington, Seattle, WA, United States.*

*2. Health Canada, Ottawa, ON, Canada.*

**Abstract:** Background: Climate change and its consequences can result in shocks and stresses that may affect population health and health systems. The extent to which health systems are prepared for and have the capacity to manage risks will determine their resilience in coming decades. Modifying current programs to manage each climate-related hazard separately may lead to inadequate preparation to manage multiple and synergistic exposures. Methods: Conducting a climate change and health stress test goes directly to the question of how well health systems could manage extreme weather and climate events, climate-sensitive disease outbreaks, and other climate-related possibilities outside the range of historic experience. A climate change and health stress test consists of three stages: (1) preparation, including identifying priority climate-sensitive health outcomes for the stress test and developing desk-based hypothetical situations (scenarios) that would shock or stress the capacity of health systems; (2) conduct a climate change and health stress test workshop to evaluate the extent to which communities and health systems would likely be able to manage the shocks and stresses, and identify additional resources, tools, and policies that could prevent adverse population health consequences associated with the hypothetical situations; and (3) summarize and prioritize the recommendations and communicate to key stakeholders. Results: Conducting a climate change and health stress test can facilitate understanding shocks and stresses that could overwhelm health systems, and identifying options to increase the capacity of communities and health systems to prepare for and manage the climate-related shocks and stresses that could occur over coming decades.

## **S03.04.22. Reducing Morbidity and Mortality Due to Extreme Heat: A Call for Evidence-Based Interventions**

Gregory Wellenius

*Gregory A. Wellenius<sup>1</sup>, Kate R. Weinberger<sup>1</sup>*

*1. Epidemiology, Brown University, Providence, RI, United States.*

Abstract: Extreme heat is an established and significant threat to public health across the globe. We estimate that in the US extreme heat events (defined as temperatures  $\geq$  97.5th percentile of local daily mean temperature) account for approximately 3,658 deaths per year, and the impact of heat on the risk of non-fatal events such as hospitalizations and emergency department visits is likely even larger. National analyses suggest that projected climate change could lead to thousands of additional deaths per year due to extreme heat. Additional adaptation measures at the individual, household, and community levels will be essential to avoid the worst of these health impacts. Many communities have already implemented adaptation measures in order to reduce heat-related morbidity and mortality in the present and the future. For example, in Philadelphia, New York City, and across New England, the research community and key stakeholders have collaborated to refine the guidelines for issuing National Weather Service (NWS) heat advisories or excessive heat warnings with the aim of better protecting people in the face of extreme heat events. Implementation of these and other adaptation measures should be viewed as a critical step in the right direction. However, there is relatively little evidence regarding the effectiveness of existing or emerging approaches to reduce heat health impacts, and the available evidence is mixed. For example, our recent findings suggest that NWS heat alerts between 2001 and 2006 were not associated with appreciable reductions in rates of death or hospitalization in most locations, potentially missing a valuable opportunity to avert a substantial number of heat-related deaths. Emerging results highlight the need to better link heat warning systems to effective intervention strategies to reduce heat-related health effects, as well as the need for adaptation efforts to be based on rigorous evidence of which approaches are likely to be most effective.

### **S03.04.23. Early Warning System for Infectious Diseases at the European Center for Disease Prevention and Control (ECDC)**

Jan Semenza

*Jan C. Semenza<sup>1</sup>*

*1. Scientific Assessment Section , European Centre for Disease Prevention and Control , Stockholm, Sweden.*

Abstract: As part of climate change adaptation, early warning of environmental precursors of diseases constitutes a proactive public health intervention. It entails risk analysis, monitoring of environmental precursors of disease through sensors, event detection, warning, communication, dissemination, and response. The intent is to forecast an epidemiological event by providing lead-time for a rapid response in order to prepare for adverse consequences and to minimize its impact. The European Centre for Disease Prevention and Control (ECDC) has developed a quasi-real-time, web-based platform, the ECDC Vibrio Map Viewer, to monitor environmentally suitable marine areas for *Vibrio* growth using remotely sensed sea surface temperature and salinity. *Vibrio* spp. are aquatic bacteria that are ubiquitous in warm estuarine and coastal waters with low to moderate salinity; the environmental suitability of *Vibrio* growth in the Baltic Sea is projected to expand in a warming climate. *V. parahaemolyticus*, *V. vulnificus* and non-toxicogenic *V. cholerae* (non-O1/non-O139) are pathogenic in humans, although they are not responsible for widespread epidemics. ECDC generates weekly forecasts and potential alerts that are disseminated to public health decision makers, along with different response options for their consideration: public access to a beach should be temporarily denied for public safety purposes; warnings should be issued when the environmental suitability of *Vibrio* infections is imminent; or alerts should be issued to notify health care providers and at risk individuals, such as the immune-compromised.

**S03.04.24. Title: Assessing Health Vulnerability and Adaptation to Climate Change: Health Canada's Guidance for Public Health Officials**

Peter Berry

*Peter Berry<sup>1</sup>*

*1. Health Canada, Ottawa, ON, Canada.*

Abstract: Climate variability and change are increasing risks to the health of Canadians in communities across Canada. Addressing the challenges posed by climate change requires knowledge of risks from current climate hazards, projected impacts of future climate change, the unique vulnerabilities facing specific populations, communities or regions, and measures to effectively protect health. An increasing number of health authorities from local to national levels in Canada are undertaking assessments to expand understanding of climate change impacts on health and adaptation options, educate and engage stakeholders and the public and influence policy development. Climate change and health vulnerability and adaptation assessments: (1) Provide information on the expected distribution and severity of future climate change and health impacts to health and emergency management officials, stakeholders and the public; (2) Inform efforts to mainstream information on the health impacts of climate change into existing policies and programs and/or develop new initiatives to reduce the health impacts of climate change; and (3) Support the development of inter-sectoral relationships and collaborations to influence upstream determinants of health in the context of greater climate change stressors. Building on assessment guidance developed by the World Health Organization, Health Canada developed the "Climate Change and Health Vulnerability and Adaptation Assessment Workbook" that integrates greater considerations of gender and Indigenous Population issues and knowledge into assessment steps along with guidance and indicators for gauging the resilience of health systems and services to climate change impacts.

### **S03.04.25. Climate Change Policy: What Has Happened? What Can We Do?**

Mary Rice

*Mary B. Rice<sup>1</sup>*

*1. Department of Medicine, Beth Israel Deaconess Medical Center, Boston, MA, United States.*

"Abstract: In 2015, at the Conference of Parties 21 Summit in Paris, nearly every country on the planet agreed to set "nationally determined contributions" to limit greenhouse gas emissions, with the goal of holding the increase in the global average temperature to below 2 °C above pre-industrial levels. Since then, the United States has indicated it will pull out of the Paris agreement and has rolled back regulations to reduce emissions from power plants and motor vehicles. Key policy developments in the United States, Europe and China will be reviewed, with a focus on how health effects research has informed climate policy. The presentation will conclude with a discussion of the role of physicians and scientists as educators and advocates for health-conscious energy policy. "

## S03.04F. Exposures to Emerging Trace Elements

### S03.04.26. Assessing and Reducing Risks from Mining of Technology Critical Elements

Michael Parsons

*Michael B. Parsons<sup>1</sup>, Jeanne B. Percival<sup>2</sup>, Alexandre J. Desbarats<sup>2</sup>*

*1. Natural Resources Canada, Geological Survey of Canada, Dartmouth, NS, Canada.*

*2. Natural Resources Canada, Geological Survey of Canada, Ottawa, ON, Canada.*

**Abstract:** In recent years, there has been a rapid increase in the global demand for many elements used in green energy and high-tech applications, including antimony (Sb), cobalt (Co), indium (In), lithium (Li), niobium (Nb) and the rare earth elements (REE). Canada has abundant resources of these critical elements, and many companies are working to bring new mines into production. However, we know very little about the potential environmental impacts of mining critical elements compared to mining other commodities such as gold or copper. Processing resources such as REEs has led to environmental degradation in some parts of the world, but there are few published studies of these environmental impacts and related risks to human health. This talk will summarize the key geoenvironmental characteristics of critical element deposits, including results from recent studies of the St. Lawrence Columbian Mine in Oka, Quebec. This mine operated from 1961 to 1976 and at the time was one of the largest Nb producers in the world. Samples of waste rock, tailings, slag, surface water, and groundwater were collected from 2015 to 2018. Mineralogical analyses show that in waste rock and tailings most uranium (U), thorium (Th) and REEs are hosted by low-solubility oxide and silicate minerals. However, some REEs and fluorine (F) are contained in minerals such as calcite and fluorapatite, which are relatively soluble under weathering conditions. Smelter slag at the mine contains concentrations of U, Th and radioactive isotopes that exceed Canadian guidelines for the disposal of radioactive waste. Measurements of U, Th, F, Nb, REEs, and radionuclides in tailings seepage and pit lake waters indicate that these elements are relatively immobile in oxic surface waters, but may be transported in deeper, anoxic groundwaters. The results of this research should help to improve environmental predictions for future Nb- and REE-mining projects and support the development of new environmental guidelines.

### **S03.04.27. Using Hair Analysis to Assess the Exposure Level of Rare Earth Elements among Rural Housewives**

Bin Wang

*Bin Wang<sup>1</sup>, Zhiwen Li<sup>1</sup>, Lailai Yan<sup>3</sup>, Jingxu Zhang<sup>2</sup>, Jufen Liu<sup>1</sup>*

*1. School of Public Health, Institute of Reproductive and Child Health, Peking University, Beijing, China.*

*2. Department of Child, Adolescent and Women's Health, School of Public Health, Peking University, Beijing, China.*

*3. Central Laboratory of School of Public Health, Peking University, Beijing, China.*

Abstract: Several studies have observed that population living near coal mining areas may have higher exposure level of rare earth elements (REEs). However, it is still a challenge to assess their exposure level of REEs, and the adverse effects of REEs on human health were also rarely investigated by an epidemiological study. Our study aimed to use hair analysis to assess their exposure level of REEs among women in Shanxi Province, which has the leading coal production around the world. In addition, we investigated the associations between hair concentrations of REEs and risk of hypertension among female adults and fetal neural tube defects (NTDs). About 14 concerned REEs in the specific hair sections were analyzed including lanthanum, samarium, europium, gadolinium, terbium, dysprosium, holmium, erbium, thulium, ytterbium, lutetium, yttrium, cerium, praseodymium, and neodymium. Population exposure level to indoor air pollution from coal combustion (IAPCC) was evaluated by the questionnaires of energy usage characteristics and life style. It was observed that hair concentrations of 13 REEs were overall positively correlated with the exposure level of IAPCC, except for europium. For the rural women, our study results revealed that the hair concentrations of the 14 REEs, except for europium, in hypertensive case women were higher than those in controls. The univariate odds ratios (ORs) of the 14 REEs were systematically > 1, of which four REEs (i.e. dysprosium, thulium, ytterbium, and yttrium) had adjusted ORs > 1. In addition, we found that hair REEs concentrations grown during the early pregnancy had potential adverse effect on NTD risk. It was concluded that hair REEs could be used as a marker to indicate population exposure level to REEs and may be a risk factor of the development of hypertension and fetal NTDs.

### **S03.04.28. Assessing Potential Exposure to Rare Earth Elements in Household Dust Via the Inhalation Exposure Pathway**

Albert Juhasz

*Albert Juhasz<sup>1</sup>, Farzana Kastury<sup>1</sup>, Pat E. Rasmussen<sup>2</sup>*

*1. Future Industries Institute, University of South Australia, Adelaide, SA, Australia.*

*2. Health Canada, Ottawa, ON, Canada.*

**Abstract:** As the commercial importance and prevalence of rare earth elements (REE) in consumer products grows, information about REE concentrations in the indoor environment has become increasingly relevant. Household dust acts as a sink for a wide variety of compounds from consumer products, building materials and outdoor sources, and is a useful medium for assessing residential exposures. This study investigated potential human exposure to REE in household dust via the inhalation exposure pathway. Household dust, collected from homes in 13 cities across Canada, was characterised for its elemental composition. Among the REE, cerium, lanthanum, neodymium and praseodymium were most prevalent with higher concentrations observed in homes of smokers compared to non-smokers. This was attributed to particles of mischmetal alloy emitted from cigarette lighter flints. Following household dust fractionation to a particle size of < 10 µm, potential REE exposure was assessed using an inhalation in vitro assay encompassing Hatch's solution as a simulated lung fluid. The inhalation assay was linked to the ingestion pathway by extending the assay to include gastrointestinal (GI) solutions. This simulated a scenario where following inhalation, household dust was cleared from the lung, swallowed and passed through the GI tract. Variability in REE bioaccessibility was observed suggesting that REE source is an important parameter influencing dissolution in biological fluids which may impact on human health exposure via the inhalation pathway.

### **S03.04.29. Platinum Group Elements, Lanthanoids and Other Metals of Concern in Road Dust and Airborne Particles in Houston, TX**

Ayse Bozlaker

*Ayse Bozlaker<sup>1</sup>, Shankararaman Chellam<sup>1</sup>*

*1. Zachry Department of Civil Engineering, Texas A & M University, College Station, TX, United States.*

Abstract: Metal-content of inhalable fine particulate matter ( $PM_{2.5} \leq 2.5 \mu m$  in diameter) can increase the risk of adverse health outcomes while simultaneously providing clues to their origins. A unique aspect of Houston aerosols is their lanthanoid enrichment emanating from crude oil-cracking units in petroleum refineries with smaller contributions from oil combustion and shipping activities. Similarly, concentration pattern of platinum group of elements (PGE) used as unique markers of tailpipe emissions from light-duty vehicles is distorted from the crust in heavily trafficked areas, e.g., Texas. Evidence is also provided for transatlantic North African desert dust and its impact on mass and elemental composition of atmospheric aerosols during summers through detailed elemental analysis. Consequently, comprehensive characterization of airborne particulates for a wide range of elements will assist in identifying and apportioning various natural and anthropogenic sources. Our analytical method recently optimized for simultaneous measurement of three PGEs of Rh, Pd, and Pt, 14 lanthanoids, and numerous other trace- to major-elements will be briefly described in this presentation along with a summary of our measurements in source and receptor particulates in the greater Houston area. Our focus will be on road dust and airborne particulate matter, two important compartments of environmental PGEs, lanthanoids, and other anthropogenically polluted elements. Possible sources of primary particulate emissions and their contributions to  $PM_{2.5}$  mass concentrations in Houston air will also be summarized from source apportionment studies based on elementally characterized receptor data. Finally, compositional differences in ambient  $PM_{2.5}$  under the influence of different source emissions will be discussed using ternary diagrams and abundance pattern of lanthanoids.

### **S03.04.30. Platinum Group Element Enrichment in Road Dust and Their Human Bioaccessibility**

Clare Wiseman

*Clare Wiseman<sup>1</sup>, Jianjun Niu<sup>2</sup>, Christine Levesque<sup>2</sup>, Marc Chénier<sup>2</sup>, Pat E. Rasmussen<sup>2</sup>*

*1. School of the Environment, University of Toronto, Toronto, ON, Canada.*

*2. Exposure and Biomonitoring Division, Environmental Health Science and Research Bureau, HECSB, Health Canada, Ottawa, ON, Canada.*

Abstract: Road dust is enriched with a range of metals and metalloids of human health concern, including technology-critical elements, such as the automotive exhaust catalysts platinum (Pt), palladium (Pd) and rhodium (Rh). To date, inhalable road dust particle size fractions have not been fully characterized in terms of their elemental composition or bioaccessibility upon uptake in the human lung. The goal of this study was to examine platinum group element (PGE) enrichment patterns and bioaccessibility in road dust particle size fractions of physiological relevance for human respiratory exposures (<10 microns). Inhalable particle size and bulk road dust samples (n=65) were collected in cooperation with the City of Toronto. Total (bulk) PGE concentrations were measured in dust samples using NiS fire-assay-INAA. The lung simulant, Gamble's solution, was used to extract the bioaccessible fractions of PGE (n=16). Metal concentrations were measured in extracts with ICP-MS. Using a laser diffraction particle size analyzer, the bulk of particles (50th percentile) in isolated inhalable sweeps had a measured diameter ranging between 6.5 and 14.6 microns. Pd occurred at the highest relative geometric concentrations in inhalable fractions of road dust (152 µg/kg), followed by Pt (geomean: 55 µg/kg) and Rh (geomean: 21 µg/kg). Iridium (Ir) was also detected in inhalable road dust fractions (geomean: 0.23 µg/kg). PGE concentrations were highest in the inhalable particle size fractions of road dust relative to bulk samples, with enrichment ratios that ranged from a low of 2.5 for Pd to a high of 7 for Ir. Pt was the most soluble in Gamble's solution (geomean: 16%), while Rh and Pd had geomean soluble fractions of 14% and 3.4%, respectively. Although PGE are used as catalysts in an elemental form, the study demonstrates that PGE in road dust are bioaccessible in the human lung.

S03.04G. The NIH Prisms Program: Informatics Systems for Pediatric Asthma Research with Integrated Sensor-Based Exposure, Context and Health Monitoring

**S03.04.31. Monitoring Particulate, PAH, Allergen and Microbial Exposures in Asthmatic Kids**

Steven Chillrud

*Steven Chillrud<sup>1</sup>, Jeff Blair<sup>2</sup>, Beizhan Yan<sup>1</sup>, Qiang Yang<sup>1</sup>, James Ross<sup>1</sup>, Masha Pitiranggon<sup>1</sup>, Luis M. Acosta<sup>3</sup>, Adnan Divjan<sup>3</sup>, Matthew Perzanowski<sup>3</sup>*

*2. AethLabs, San Francisco, CA, United States.*

*3. Environmental Health Sciences, Mailman School of Public Health of Columbia University, New York, NY, United States.*

Abstract: The overall goal of the PRISMS Program is to develop sensor-based measurement and informatics platforms of environmental, physiological, and behavioral factors for epidemiological studies of asthma, and eventually other chronic diseases, in the pediatric population. As part of PRIMSS, Columbia and AethLabs are developing and evaluating a modular array of miniaturized air monitors for use as personal and residential sensors for testing hypotheses on asthma development and asthma exacerbation. Our overall approach is to develop flexible monitors that can be used for different study designs and provide archive samples that can be stored for future hypothesis testing. Our real-time monitors measure spatial and temporal variations of potential acute asthma stressors (black carbon, UV-active particulate matter from sources such as environmental tobacco smoke, wood smoke or incense, particle reactive PAHs, relative humidity and temperature). The residential monitor can also integrate 3rd party commercial sensors for estimating fine and coarse particulate matter mass. In addition, we have built an archive monitor prototype that can collect two integrated samples that are either spatially- or time- resolved, and can be archived for subsequent lab analysis. Tri-axial accelerometer and GPS chips are integrated into our personal monitors allowing determinations of location, wearing compliance and activity related parameters. Data is transmitted to the PRISMS platform for storage and analytics. Progress has been made in developing a suite of asthma-related exposure measurements for archived integrated samples including PM2.5 and PM10 mass, volatile and semi-volatile organic compounds, and particulate-bound elements. We are validating filters for collecting integrated samples for analyses of airborne allergens (mouse, dust mite and cockroach) and PCR based microbial assays; preliminary results shows that the 2 hour of subway sampling provided enough mass for these bioassays.

### **S03.04.32. Clouded-Based Wearable and Stationary Sensors for Monitoring Air Pollution Exposure in Pediatric Asthma Research**

Zhenyu Li

*Baichen Li<sup>1</sup>, Quan Dong<sup>1</sup>, Nam Tran<sup>1</sup>, Mona Zaghoul<sup>2</sup>, Zhenyu Li<sup>1</sup>*

*1. Biomedical Engineering, George Washington University, Washington, DC, United States.*

*2. ECE, George Washington University, Washington, DC, United States.*

**Abstract:** Asthma is a common chronic disease of the airways, which affects 26 million people and costs \$56 billion each year in the US alone [1]. In particular, 7 million children suffer from asthma which causes more than 10 million lost school days due to asthma exacerbations. Although triggers to pediatric asthma exacerbations are well recognized such as airway infections, allergens, tobacco smoke, air pollution, and exercises, how the interactions between the environmental factors and the patients' biological and behavioral characteristics determine the susceptibility to and timing of such events is not well understood. One significant barrier to the causal understanding is the lack of objective measures on exposure metrics correlated with patient physiological responses and activities. Therefore, there is a significant unmet need to develop integrated sensor monitoring systems that can be deployed in a child's daily life to collect real-life exposure, context and health data for epidemiological studies of asthma. As part of the NIH PRISMS program, we have developed a wearable aldehyde sensor and a stationary Ozone and NO<sub>2</sub> monitor for pediatric asthma epidemiological research. The stationary sensor also includes a single-board computer with WiFi and Bluetooth Low Energy (BLE) capabilities, which can function as a gateway to a cloud-based informatics system for data storage, management and analytics. Here we will describe the design, manufacture, test, calibration and deployment of these sensors in a pilot clinical study. The sensor performances in the lab including sensitivity, dynamic range, linearity, drift, and temperature and humidity dependence will be presented. Integration of the sensors with a cloud-based PRISMS informatics system through the gateway will also be presented. Future work and potential applications to other diseases affected by environmental exposure will be discussed. [1] CDC. Asthma Facts - CDC's National Asthma Control Program Grantees. 2013.

### **S03.04.33. Development and Evaluation of the TEMU Personal Exposure Monitor for a Rural Children's Asthma Intervention Study**

Abstract: Managing pediatric asthma in low-income populations living in rural agricultural communities is challenging for many reasons, including unique sources of indoor and outdoor air pollution that may trigger symptom exacerbations. Data from these settings are few. As a member of the NIH PRISMS consortium, we designed and explored the feasibility of a new exposure monitoring system called the TEMU for the Home Air in Agriculture Pediatric Intervention (HAPI) study in which low-income Latino children with asthma receive household HEPA air filtration units in a randomized intervention in rural Yakima, WA. During Winter 2017-18 season, a subset of 6 children from the HAPI study were recruited to use the TEMU system - a combination of a household indoor real-time particle monitor, a wearable personal real-time particle monitor, and a wireless tablet-based daily symptom diary. We observed good compliance and acceptance of the wearable monitor for most participants, however 2 participants chose to stop using the system after the first day. For those that successfully used the system, geocoded particle concentration data from the wearable monitor illustrated exposure differences between home, school and other community locations. Generally, household indoor particle monitoring data were correlated with personal exposures when children were at home, but were different when children were not at home. Particles collected both from the children's personal and household monitors will be archived for future analyses that may indicate the predominant sources of airborne particle exposures in this setting.

### **S03.04.34. Scaling Up Data Integration and Analysis of Sensor Data for Pediatric Asthma**

**Abstract:** Childhood asthma is a serious chronic disease affecting 9.3 percent of the American pediatric population. Current epidemiological research tools are limited in the types of information they can collect and aggregate, which restricts their predictive power. The NIH Pediatric Research using Integrated Sensor Monitoring Systems (PRISMS) program is predicated on the idea that better, more accurate sensing of physiology, environmental exposures, and local context can greatly enhance scientific and clinical understanding towards more effective management of chronic disease. At the PRISMS Data and Software Coordination and Integration Center (DSCIC), we are developing a general data integration and analysis architecture, building upon Apache Kafka and Apache Spark, with several advantages. First, our system enables biomedical researchers to (1) collect streaming data from multiple sensors, including at-home and personal pollution monitors, environmental and weather sources, geospatial features and personal trajectories, and Ecological Momentary Assessments (EMA) data collected from subjects' mobile phones; (2) map these heterogeneous datasets to a common schema to facilitate analysis; and (3) train and apply statistical models over both streaming and historical data at scale. Our target applications include prediction algorithms for asthma exacerbations, identifying key personal-level triggers, and eventually providing closed-loop interventions. We will present an overview of the PRISMS-DSCIC data integration and analysis architecture, demonstrate a statistical analysis use case, and describe how our architecture enabled the development of a novel data mining approach using publicly available spatial data (OpenStreetMap) and meteorological data (Dark Sky) to build an air quality model for predicting the concentration of PM<sub>2.5</sub> at a fine spatiotemporal resolution.

## S03.04H. Women at Work: How Exposed Are They?

### S03.04.36. Sex Differences in Occupational Risks in Ontario Workers

Paul Demers

*Paul A. Demers<sup>1</sup>, Jill MacLeod<sup>1</sup>, James K. Jung<sup>2</sup>, Chloe Logar-Henderson<sup>1</sup>, Sharara Shakik<sup>1</sup>, Jeavana Sritharan<sup>1</sup>, Victoria Arrandale<sup>1</sup>, Chris McLeod<sup>3</sup>*

**Abstract:** Introduction When examining the risk of occupational disease, it is common to identify discordant results by sex. While these differences may be due to chance or non-occupational factors, they may also represent unidentified differences in occupational risk. Here we illustrate the challenges of interpreting discordant results by sex using the lung cancer results from the Occupational Disease Surveillance System (ODSS). Methods The ODSS uses a cohort of 2,190,246 Ontario workers (34% female) to examine occupational risks for lung cancer. The cohort was created by linking data from the workers compensation system (1983-2016) with Ontario tumour registry and other health data. Cox-proportionate hazard models were used to calculate sex-stratified age-adjusted hazard ratios (HR) and 95% confidence intervals (CI). Results There were 25,469 lung cancer cases among men and 9,192 among women. Using broad industry groups (10 categories) statistically significant ( $p < 0.05$ ) elevated results for men in mining, construction, transportation, and finance and for women in wholesale and retail trade. Using broad occupational groups (22 categories), the significant results for men and women were congruent for blue-collar categories, though the HRs were consistently higher in women versus men. For example, the HRs for machining jobs were 1.09 (CI=1.03-1.13) for men and 1.32 (CI=1.15-1.51) for women, and HRs for transportation equipment operating were 1.38 (CI=1.32-1.45) for men and 1.52 (CI=1.26-1.82) for women. In contrast, women had increased HRs in clerical (1.19, CI=1.10-1.28), sales (1.21, CI=1.10-1.32), and service occupations (1.11, CI=1.04-1.18), which were not observed among men. Conclusions Industry results were largely discrepant, while occupational results were similar for blue-collar groups with potential exposure to established carcinogens. Some elevated risks could be due to non-occupational factors (e.g. smoking), but others may be due to unrecognized hazards.

### **S03.04.37. Sex Differences in Occupational Physical Activity**

Abstract: Strong evidence supports that participation in recreational physical activity (PA) is beneficial for health. However, PA is also derived from occupational, household and transportation-related activities, among which perhaps the most important is occupational, due to the time spent at work and that some jobs entail considerable PA. In contrast to recreational PA, the effects of occupational PA have been studied to a much lesser extent. Though, energy expenditure regardless of its source should have similar beneficial effects, certain jobs are conducted in settings that may contain hazardous exposures, whereby increasing occupational PA may actually exacerbate harmful effects. As sex differences may affect activity levels and/or the metabolism of certain chemical exposures, research should incorporate the consideration of sex and gender. We examined sex differences in occupational PA levels using data from a population-based case-control study of lung cancer conducted in Montreal, Canada (889 men, 564 women). In this study, lifetime job history was collected via in-person interviews; for each job, the main tasks conducted were also obtained. The energy expenditure for each job-related task, in units of metabolic equivalent of task (MET), was determined via expert assessment by an industrial hygienist and an exercise physiologist. In preliminary analysis, the most common jobs held by men and women included accountant, occupations related to management and administration, clerk, cleaner and waiter. Despite these occupations being mostly white collar, MET values were found to be higher in men than in women (t-test  $p < 0.05$  for: sales clerk, cleaner and hand packager). Further analysis will be conducted to compare the job profiles, based on job titles, industries and tasks, by sex. Less is known about occupational determinants of health in women than men, and understanding sex differences in occupational energy expenditure is one avenue to inform on prevention efforts.

### **S03.04.38. Occupational Exposures among Women Based on CAREX Canada's Estimates**

Cheryl Peters

*Cheryl Peters<sup>1</sup>, Amy L. Hall<sup>2</sup>, Calvin B. Ge<sup>3</sup>, Paul A. Demers<sup>4</sup>*

*2. International Agency for Research on Cancer, Lyon, France.*

*3. Institute for Risk Assessment Sciences, Universiteit Utrecht, Utrecht, Netherlands.*

*4. Occupational Cancer Research Centre, Cancer Care Ontario, Toronto, ON, Canada.*

**Abstract:** Introduction CAREX Canada develops estimates of the prevalence of exposure to carcinogens. This data can be shown by sex, but potential sex-differences in prevalence of exposure were not considered. The objective of this work is to a) highlight workforce differences by sex, and b) to identify industries/occupations where women's exposures may be underrepresented in CAREX Canada estimates. Methods Census data were obtained from Statistics Canada for 2006 and 2016. Comparisons of prevalence by sex were done by industry and occupation, as well as between these 2 time points to identify categories predominantly composed of female (or male) workers. Exposure prevalence estimates were compared by sex, and broad trends in carcinogen exposure prevalence between female and male workers were calculated. Results The 2006 workforce was 47.3% female, and this increased slightly in 2016 (47.8%). However, stark differences occur in some industries; for example, health care was strongly female-dominated (82.1% female in 2006 and 2016), and construction was strongly male-dominated (12% female in 2006 and 2016). Nearly all industries were stable ( $\leq 2\%$  change) in terms of sex balance over the census periods. CAREX estimates indicate that men strongly dominate the carcinogen-exposed workforce in Canada, with 81% of the exposures (on average), reflecting occupational categories where 'traditional' carcinogens are well-known to occur (such as construction, mining, and manufacturing). An emerging exposure where this was not the case was antineoplastic drug exposures, which are dominated by female workers (75% of those exposed). Conclusions CAREX estimates may give a false impression that exposure to carcinogens is less important in females than males due to our better knowledge of exposure patterns in male-dominated industries and its focus on the more "traditional" carcinogens.

### **S03.04.39. Occupational Exposures among Nail Technicians in Toronto, Canada**

**Abstract:** Introduction: Nail salons have proliferated recently. In Toronto, Canada, many of these salons are small businesses that employ immigrant women. The Healthy Nail Salon Network has undertaken initiatives to better understand the work and health of nail technicians in Toronto, ON. We present preliminary results of a study of chemical, ergonomic and psychosocial hazards in Toronto nail salons. Methods: Sampling has been completed in five salons. Personal air samples were collected in the workers' breathing zone to assess for exposure to VOCs, phthalates, organophosphate esters. Stationary continuous monitors were also used to assess formaldehyde and particulates in the work environment. The Quick Exposure checklist (QEC) was completed to assess the ergonomic risk associated with common nail salon tasks, and the Karasek job control demand scale was used to investigate job strain. Results: In total, 10 workers participated in the sampling. Overall, 16 of the 20 VOCs investigated were detected. Acetone, ethyl acetate, methyl methacrylate, n-butyl acetate and toluene were detected in all samples. Formaldehyde (personal) exposures ranged from 16.5ppb to 39.6ppb (AM 24.2ppb). Methyl methacrylate ranged from 0.40mg/m<sup>3</sup> to >18mg/m<sup>3</sup> (AM 3.9 mg/m<sup>3</sup>). Plasticizers were also identified in air: 8 phthalates and 6 organophosphate esters were detected in at least one sample. For manicure and pedicure tasks, the QEC results showed high or very high back (static) and neck ergonomic exposures; shoulder and wrist/hand exposures were low/moderate. Results from the Karasek scale placed 83% of participants in the high job strain domain (low decision latitude and high job demands). Conclusions: These preliminary results indicate that nail technicians have a variety of potentially hazardous exposures, not limited to chemicals. Further results from 26 enrolled salons will provide a more complete picture of these exposures among nail technicians in Toronto, Canada.

### **S03.04.40. Women at Work: How Exposed Are They?**

**Abstract:** Aim: To use workers' compensation claims for occupational disease and illness over a 25-year period as an indicator for women's exposures at work. Methods: Accepted compensation claims and labour force statistics for workers in the Canadian province of British Columbia were used to calculate annual rates of occupational disease and illness for women compared to men from 1992 to 2016. Results: Over 86,000 compensation claims for occupational disease and illness were accepted during the study period, but 7% were missing data on gender. Infectious disease rates increased over time and were always higher for women than men (29 versus 4 cases per 100,000 in the last five years of follow-up). Hearing loss rates decreased over time and were always higher for men than women (24 versus 1 case per 100,000 in the last five years). Skin condition rates decreased over time and were similar for men and women (3 cases per 100,000 men and women in the last five years). Mental disorder rates increased over time but more so for women than men (from 9 cases per 100,000 in the first five years of follow-up for both men and women to 19 cases for men and 26 cases for women in the last five years). Small cell sizes (<5 cases annually) for cardiovascular and respiratory diseases and for neoplasms precluded rate calculations for women. Small cell sizes were also an issue for environmental exposures but, where comparisons were feasible, men always had higher rates than women. Discussion: Women were more likely to have claims related to infectious and mental stress exposures, while men were more likely to have claims related to environmental and noise exposures. An exception was skin conditions (dermatitis) with similar rates for men and women over time. Despite significant shifts in labour force participation by women, claims rates for occupational conditions remain highly gendered. Next steps include stratification of disease and illness rates by occupation.

Abstract: Air pollution risk assessments often use results from epidemiologic studies to quantify health impacts of air quality changes to individual pollutants, but tend not to account for exposure to complex mixtures. Multipollutant statistical models consider collinearity among pollutants by identifying mixtures commonly emitted from specific sources. Using a proof-of-concept version of the environmental Benefits Mapping and Analysis Program-Community Edition (BenMAP-CE) we aim to answer: (1) can the results from multipollutant statistical models (joint effect models) be used in air pollution risk assessments?; (2) how does the procedure for quantifying population health impacts differ between a single and multipollutant context? We identified studies using joint effect models with/without interactions to estimate the risk of air pollutant-attributable asthma emergency department (ED) visits. These studies examine associations between short-term criteria pollutant exposures (O<sub>3</sub>, PM<sub>2.5</sub>, CO, NO<sub>2</sub>, SO<sub>2</sub>) and PM components, which represent predefined source groupings (oxidant gases, secondary pollutants, traffic, power plant, criteria pollutants). We use results from these studies and daily air quality data in BenMAP-CE for a case study in the city of Atlanta and the state of Georgia. Preliminary results indicate: (1) interaction models yield larger estimates of pollutant-attributable asthma ED visits; (2) warm season impacts are greater than cold season; and (3) certain pollutant groups yield a negative number of cases. BenMAP-CE runtime for multipollutant models was commensurate with runtime for single pollutant models. This study suggests that risk assessments for multipollutant exposures are feasible, but data-intensive. Future risk assessments using single and multipollutant approaches can potentially provide a more comprehensive evaluation to inform air quality management strategies. Disclaimer: The views expressed do not necessarily reflect the views/policies of U.S. EPA.

## **O04.01.02. Regional Assessment of Current and Future States of GHGs Emissions: Impacts of Transportation Policy Scenarios**

Abstract: Estimating the future state of greenhouse gases (GHGs) and air quality associated with transportation policies and infrastructure investments is key to the development of meaningful transportation and planning decisions. This study describes the design and application of an integrated transportation emission model for the prediction of GHGS in CO<sub>2</sub>eq in the Greater Montreal Region as a result of transport policy scenarios and Land use scenarios. For this purpose, a travel demand model linked with models for traffic assignment and emissions, was used to simulate GHG emissions in a base year (2008) and a horizon year (2031) while incorporating population and demographic projections. Various stakeholders were consulted in the development of future scenarios affecting land-use and transportation through a web-based survey and workshop. In the 2031 business as usual scenario, an average decrease of 30% in GHG emissions was estimated compared to the 2008 base case. This decrease is primarily attributed to projected improvements in vehicle technology. The modelling system was used to evaluate the impact of a 20% market penetration in electric vehicles, revealing significant reductions in GHG emissions across the region. Work is currently underway to estimate the emissions of nitrogen oxides (NO<sub>x</sub>) and NO<sub>2</sub> concentrations to assess air quality and individuals' daily exposure by tracking activity locations and trajectories of the population and observe the level of reduction in daily exposures compared to the base case. This study is funded by a collaborative grant from the Canadian Institutes of Health Research (CIHR) and the Natural Sciences and Engineering Research Council of Canada (NSERC) and Ouranos.

### **O04.01.03. Estimation of the Effect of Hypothetical Air Pollution Scenarios on Lung Function in the Southern California Children's Health Study: An Application of G-Computation**

Robert Urman

*Robert Urman<sup>1</sup>, Erika Garcia<sup>1</sup>, Kiros Berhane<sup>1</sup>, Rob McConnell<sup>1</sup>, Frank Gilliland<sup>1</sup>*

*1. Preventive Medicine, University of Southern California, Los Angeles, CA, United States.*

**Abstract:** Background: We have shown improved lung function with decreasing pollutant levels across several cohorts from the Southern Californian Children's Health Study (CHS). In this study, we estimate the benefits of air pollution reduction on lung function growth under several hypothetical scenarios by implementing g-computation, a method based in the counterfactual framework. Methods: Forced expiratory volume in 1 second (FEV1) and forced vital capacity (FVC) were assessed repeatedly among 2120 adolescents across 3 CHS cohorts spanning nearly 2 decades. Averages of regional nitrogen dioxide (NO<sub>2</sub>) and particulate matter  $\leq 2.5 \mu\text{m}$  (PM<sub>2.5</sub>) were taken from 1994-1998, 1997-2001, and 2007-2011, which correspond to lung growth from 11 to 15 years of age in these cohorts. Mixed-effects linear regression models, incorporating regional pollutants and key covariates, were used to model growth trajectory for each lung function measure from age 11 to 15. Compared to lung function growth based on observed data, we estimated the difference in growth had levels of NO<sub>2</sub> and PM<sub>2.5</sub> either 1) remained at the average concentration observed in 1994-1998 or 2) met one of several existing or hypothetical air quality standards (air pollution lowered only in communities exceeding the standard). Bootstrap samples (N=1000) were used to calculate confidence intervals. Results: FEV1 growth was estimated to have been reduced by 2.7% (95% CI: -3.6%, -1.8%) had NO<sub>2</sub> remained at 1994-1998 levels. Implementing standards of 30, 20, and 10 ppb for NO<sub>2</sub> were estimated to increase FEV1 growth by 1%, 3.9%, and 9.1%, respectively. Remaining at 1994-1998 levels for PM<sub>2.5</sub> was estimated to decrease FEV1 growth by 2.6%, while increases of 2.6%, 3.6%, and 4.4% were estimated had concentrations been lowered to 15, 12, or 10  $\mu\text{g}/\text{m}^3$ , respectively. Larger pollution-associated changes were estimated for FVC. Conclusion: Lowering concentrations of NO<sub>2</sub> and PM<sub>2.5</sub> would have likely resulted in better lung function in our population.

Abstract: We estimate monetized health benefits of phasing out the coal-fired power plants in Ontario and Alberta as well as in the US. We quantify these health impacts by accounting for reduced mortality due to chronic exposure to NO<sub>2</sub> (In Canada) and PM<sub>2.5</sub> (In Canada and the US). We apply the US EPA's Community Multi-Scale Air Quality (CMAQ-5.0) model and its adjoint to quantify the marginal benefits (MB) of NO<sub>x</sub> and PM<sub>2.5</sub> emissions. The adjoint model traces mortality counts back to emissions for each single source location and time. The backward simulations of the model rely on non-linear concentration-response (C-R) functions of single (PM<sub>2.5</sub>) and three-pollutant (PM<sub>2.5</sub>, NO<sub>2</sub> and O<sub>3</sub>) epidemiologic models. The simulations are done over a nested 12 km and 36 km domain, covering North America and for July 2010. Our preliminary results show health benefits for specific plants in Ontario and Alberta are between C\$ 30k-310k/ton of PM<sub>2.5</sub> and \$30-270k/ton of NO<sub>x</sub>. These values range between \$30k-580k/ton of PM<sub>2.5</sub> for plants in the US. Retrospective analysis of coal phase-out in Ontario suggests benefits of \$3.1 billion/yr, while societal benefits of the proposed phase-out in Alberta is approximated at \$2.4 billion/yr. We find significant benefits from coal phase-out in both Ontario and Alberta, and even larger benefits in the US. For Ontario, our results suggest that most of the health benefits from Ontario coal phase-out materializes in the province, whereas Alberta phase-out entails larger out-of-province benefits.

**Abstract:** Objective: We assess the societal benefits of reducing air pollutant emissions that contribute to ambient fine particulate matter (PM<sub>2.5</sub>), ozone (O<sub>3</sub>), and nitrogen dioxide (NO<sub>2</sub>) exposure and public health impacts. Recent evidence suggests that nonlinear, multi-pollutant concentration-response (C-R) models are more appropriate than traditional, linear forms used in epidemiology. We examine the implications of alternate C-R models in an emissions reduction framework. Methods: We integrate C-R models for non-accidental mortality due to PM<sub>2.5</sub>, O<sub>3</sub>, and NO<sub>2</sub> into the Community Multiscale Air Quality Model (CMAQ). This sophisticated atmospheric model and its adjoint tool allow us to trace public health impacts back to sources of pollutant emissions. We compare the monetized public health benefits of reducing emissions from sources across Central Canada at a 12 km resolution for July 2010. We apply C-R models (single or multipollutant and linear or nonlinear) derived from the 2001 Canadian Census Health and Environment Cohort (CanCHEC). Results: Our preliminary results indicate significant and widespread benefits of PM<sub>2.5</sub> and NO<sub>x</sub> (NO + NO<sub>2</sub>) emissions control, particularly in major urban areas of Central Canada. We find benefits ranging from \$400,000-800,000 per ton of reduction in PM<sub>2.5</sub> from sources in Toronto, while NO<sub>x</sub> control for the same location entails benefits of \$2,000-200,000/ton depending on the choice of C-R model. Nonlinear models consistently produce larger benefit estimates than their linear counterparts. We estimate coefficients of variation based solely on the choice of C-R model to be 0.4-0.6 for PM<sub>2.5</sub> and 0.6-1.6 for NO<sub>x</sub>. Conclusions: Our results show that the public health benefits of emission reductions are highly sensitive to C-R specification, and that

traditional C-R models may significantly underestimate the benefits of air pollution controls. Further research is needed to determine the most appropriate C-R model to support public policy.

#### **O04.01.06. A Model of Ischaemic Heart Disease in the UK that Suggests Reductions in Air Pollution Increase Overall Disease Prevalence**

Paul Wilkinson

*Paul Wilkinson<sup>1</sup>, Phil Symonds<sup>2</sup>, Emma Hutchinson<sup>1</sup>, Ai Milojevic<sup>1</sup>, James Milner<sup>1</sup>, Ben Armstrong<sup>1</sup>*

- 1. LSHTM, London, United Kingdom.*
- 2. IEDE, UCL, London, United Kingdom.*

**Abstract:** Objectives We have previously used a simple toy model to suggest that the proportion of people with ever-diagnosed ischaemic heart disease (IHD) from air pollution is heavily influenced by the effect of air pollution on case fatality as well as on disease incidence, and that this effect may lead to counter-intuitive changes on disease prevalence. We now report the results of a microsimulation model for the UK that provides more formal quantification of air pollution-related IHD morbidity burdens. Methods The model was based on a three health-state model of disease progression ('disease free', prevalent disease, death), initialized using current incidence and disease prevalence data for the UK, and using literature-based estimates of state transition probabilities and the relative risks (RRs) for disease incidence, case fatality and mortality. We examined the impact over 106 years (to extinction of the current birth cohort) of removal of all ambient PM2.5 of anthropogenic origin. Results The model indicated that for all primary outcomes (disease incidence, prevalence, and mortality) removal of anthropogenic PM2.5 would lead reductions in the absolute number of cases at young ages but appreciably increased numbers at older age-groups, reflecting improved survival and the expansion of the population at older ages. After a 106-year simulation there was a 7% net increase in the number of cases of people with ever-diagnosed ischaemic heart disease. Conclusions This modelling confirms more nuanced patterns of the impact of air pollution on IHD morbidity than those suggested by studies based on disease incidence alone. It suggests counterintuitive effects, which may increase prevalence following reduction of PM2.5 air pollution as a consequence of effects on survival. Reductions in air pollution may not therefore reduce health service costs for IHD treatment as commonly assumed.

## 004.01B. Climate and Temperature Effects

### **004.01.07. An Integrated Approach to the Development of Health-Related Climate Change Indicators for Australia**

**Abstract:** Introduction: Australia has experienced, and is projected to experience, a range of climate-related health impacts. However, there are limited tools to track the health impacts of climate change and to develop public health interventions in a timely manner. The purpose of this study was, therefore, to develop climate health indicators and to address feasibility of the indicators for Australian Stakeholders, using South Australia as a case study. Methods: due to the multidisciplinary aspects of climate-related health outcomes, a parallel mixed methods approach was adopted. The methodology included quantitative case studies focusing on spatio-temporal aspects of climate and health, and a qualitative case study for exploring stakeholder perspectives on indicator development. Results: Analysis of the relationship between heatwaves and ambulance callouts showed that Adelaide's western, inner and northern suburbs had a higher incidence rate ratio (IRR) during heatwaves compared to non-heatwaves (highest IRR of 1.26). Suburbs clustered in central Adelaide had a higher risk of emergency department visits (highest IRR of 1.41) and hospital admissions (highest IRR of 1.72). Analysis of the above-mentioned health outcomes and a range of vulnerability risk factors found four main risk factors; living alone, needing assistance with core activities, being aged above 65, and being socio-economically disadvantaged. Qualitative findings revealed a high level of stakeholder awareness of the climate-health impacts, and the need for indicators that can inform policymakers regarding interventions. They also raised several issues including lack of resources and access to data. Conclusions: The analysis has yielded an insight into vulnerable areas to heat-health effects in metropolitan Adelaide at local level. The evidence has important implications for public health planners to consider population vulnerability to climate change and use this information for policy and intervention.

#### **O04.01.08. Building Vulnerability in a Changing Climate: Using Sensors to Track Environmental Conditions and Health Outcomes during a Heatwave in Low-Income Older Adults**

Augusta Williams

*1. Environmental Health, Harvard TH Chan School of Public Health, Boston, MA, United States.*

Abstract: Human vulnerability to HWs arises from many risk factors (i.e. age, social isolation, low income, low education, minority status, non-English speaking, etc.). Older adults in particular are extremely vulnerable to extreme heat exposures. High prevalence of pre-existing disease, medications, and autonomic nervous system impairments affect the thermoregulation and perception of extreme temperature exposure, making them more susceptible to poor health outcomes during HWs. Extreme temperatures may be mitigated or exacerbated indoors compared to outdoor temperatures during HW events due to building archetype and air conditioning (AC) use. In the present study, we aimed to characterize the indoor environmental quality and relate it to health outcomes through the use of personal, indoor monitoring with 51 (central AC, n=24; non-central AC, n=27) low-income senior residents of affordable housing in Cambridge, MA during a HW event in 2015. Indoor environmental temperature, noise, and carbon dioxide were all significantly higher ( $p < 0.001$  for all) for the non-central AC building when compared to the central AC building. Within the non-central AC building, there was a 36% increase in the mean of all self-reported health symptoms during the HW event compared to the central AC building ( $p = 0.013$ ). The mean number of heat-related health symptoms was 72% higher for those in non-central AC than for central AC residents during the HW ( $p = 0.0013$ ), despite similar age, income, and prevalence of pre-existing conditions between building types. Capturing a more representative description of the temperature exposure, while also incorporating changing behavioral modifications and other important environmental features that compound the effects of heat exposure in real life settings, we gain a more comprehensive understanding of the complex impact of HWs on health and drivers of vulnerability to heat exposure.

#### **O04.01.09. Emergency Preparedness in Mi'kmaw Communities in Nova Scotia**

Amber MacLean-Hawes

*Amber MacLean-Hawes<sup>1</sup>*

*1. Department of Environment and Natural Resources, The Confederacy of Mainland Mi'kmaq, Truro, NS, Canada.*

Abstract: Climate change is expected to disproportionately affect First Nations communities due to their reliance on the environment, economic situations and geographic locations. The Climate Action program, which is part of the Confederacy of Mainland Mi'kmaq's Department of Environment and Natural Resources has been working with Mi'kmaw communities in Nova Scotia to identify climate change vulnerabilities. Throughout this process, band officials and knowledge holders from each community have been engaged in conversation to discuss the impacts of climate change on their community. Representatives from each First Nation have identified and expressed concern for climate change impacts that pose a direct threat to the health and safety of their community members, and in each case have identified Emergency Response Planning as a key vulnerability to climate change in each participating community. Through funding provided by the Department of Indigenous Services Canada, Climate Action is working to provide the information necessary to develop up to date emergency management plans that are proactive; taking predicted climate changes into consideration and providing protocols and resources necessary to effectively respond to and manage emergencies according to community needs using a holistic approach.

#### **O04.01.10. Spatial Patterns of Heat Vulnerability Constituents across Massachusetts**

Leila Heidari

**Abstract:** To address the health threat posed by increasing temperatures, it is necessary to understand where those most vulnerable to heat are located. While an overall heat vulnerability index (HVI) can identify which areas experience the composite burden of vulnerability, we elucidate which component factors drive heterogeneity in heat vulnerability across the state of Massachusetts. We constructed a Massachusetts HVI based on the HVI developed for New York State which includes factors describing 4 vulnerability dimensions: social/language; socioeconomic; environmental/urban; and elderly/social isolation. We calculated the individual HVI components for Massachusetts at the census tract level using data from the American Community Survey and National Land Cover Database at two time points, 2006 and 2011. Higher concentrations in urban areas were seen for housing density and social/language factors (race/ethnicity, non-English speaking), with lower concentrations (<10% of the population in a census tract) having the social/language vulnerability factor for the majority of the state. Poverty showed a heterogeneous pattern across the state, with elevated concentrations in both urban and rural areas. Elderly and some socioeconomic factors (disability, unemployed, and older homes) showed high concentrations not only in urban census tracts, but distributed across the state. Changes in spatial distributions of vulnerability factors between 2006 and 2011, were observed in regard to increases in older homes and unemployment, while highly developed area increased by 4.57%. HVI is multifactorial and the individual contributing factors can differentially vary across large geographical areas. Understanding the individual components of HVI can help us identify necessary sociodemographic, land use, and housing targets for statewide heat vulnerability interventions.

#### **O04.01.11. Air Conditioning and Heat-Related Mortality in U.S. and Japan: A Longitudinal Analysis**

*4. Department of Environmental Health, Harvard T.H. Chan School of Public Health, Boston, MA, United States.*

**Abstract:** Background and aim: Several studies have provided evidence of a decrease in susceptibility to heat in the last decades, but the factors responsible for such attenuation are unclear. Some have investigated the role of air conditioning (AC), with conflicting results. In this contribution, we use a novel two-stage longitudinal design and a multi-country multi-city database to assess the association between changes in air conditioning prevalence and reduction of the heat-related risks. Methods: We collected daily time series of temperature and mortality, and yearly AC prevalence, for 47 prefectures in Japan (1974-2009) and 48 cities in USA (1985-2006). In the first stage, we fitted quasi-Poisson regressions with distributed lag non-linear models for temperature (lag 10 days), repeatedly over defined windows (6 years for Japan and 4 years for US). In the second-stage, we used a novel multilevel multivariate random-effects meta-regression model to evaluate longitudinally the effect modification of AC prevalence on the derived set of splines coefficients, with multiple measures over time repeated within location. Results: In both countries, we observe an attenuation of heat-related mortality that is significantly associated with increase in AC prevalence (Japan  $p=0.028$ , USA  $p<0.001$ ), on top of an independent underlying trend ( $p<0.001$ ). For example, the relative risk for the 99th vs minimum percentile decreases from 1.114 (95% CI 1.110; 1.129) to 1.102 (1.091; 1.115) in Japan, and from 1.100 (1.081; 1.119) to 1.067 (1.048; 1.086) in USA, predicted for AC prevalence equal to 40% and 70%, respectively. Conclusions: By applying a novel longitudinal two-stage design and flexible meta-analytical models, we observed that populations became more resilient to heat over time in both Japan and US, and that this trend seems partially attributable to increase in AC use. In the next steps we will extend the analysis to evaluate the possible confounding role of time-varying covariates,

## **O04.01.12. Population Adaptation Phenomena Modelled through Functional Regression**

Abstract: The majority of weather-related health studies use past data in regression models to model the relationship between a weather exposure and a health issue. A large variety of models have been used over the years for this purpose, progressively increasing their complexity and relevance. However, gaps still exist in the understanding of weather/health relationships which, when filled, would help predicting more accurately the impact of climate change on human health. In this purpose, the present paper introduces functional regression models for environmental epidemiology studies. These models consider continuous curves instead of series of scalar values as input and/or output. Functional models are thus flexible and able to take advantage of the whole information contained in the data to estimate the weather/health relationship. Two types of functional regression models are applied in the present work to model temperature-related cardiovascular mortality in the city of Montreal, Canada. The first type of model seeks to estimate the impact of hourly temperature variations on cardiovascular mortality. The second one seeks to model how the studied relationship evolves during the year. Both applications allows new insights on the temperature/cardiovascular mortality relationship in Montreal. They especially suggest physiological adaptation effects in the response of the population to temperature, either during summer or winter. From this simple application, it is hoped that functional regression models will be used in more complex studies.

## 004.01C. Exposures and Effects in Communities

### **004.01.13. Exposure Measurement Pilot Study for Children and Adults Using Synthetic Turf Fields with Recycled Tire Crumb Rubber Infill**

Elizabeth Irvin-Barnwell

Abstract: The U.S. Federal Research Action Plan on Recycled Tire Crumb Used on Playing Fields and Playgrounds (FRAP) is a multi-agency research plan in response to concerns over the use of tire crumb rubber as infill on synthetic turf fields. The FRAP outlines specific research objectives, including characterizing tire crumb rubber and implementing a pilot-scale observational exposure characterization study. The exposure characterization study was a pilot-scale effort aimed at collecting information on how people might be exposed to chemicals in crumb rubber infill while playing on synthetic turf fields. We enrolled children and adults taking part in athletic activities on synthetic turf field in several locations to participate in questionnaire, exposure measurement, and video recording study elements. In the exposure measurement sub-study, several types of samples were collected. Next-to-field air samples were collected during the sports or training activity and dermal wipe samples were collected immediately following the activity. Collection of personal air VOC samples during the activity was attempted. Field wet wipe, drag sled, and dust samples were collected from each field. Air samples were analyzed for total suspended particulates, metals, VOCs, and SVOCs; dermal wipe samples, field wipe samples, and dust were analyzed for metals and SVOCs. Urine and blood samples were collected pre-activity and post-activity. Study recruitment and enrollment was initiated in August 2017. For the exposure characterization study, 32 athletes were enrolled, with ages ranging from 7-28. Of the 32 athletes, 25 participated in the exposure measurements sub-study; blood and urine specimens were collected from 13 and 14 participants, respectively. Additionally, 17 individuals participated in the videography component. This presentation will focus on the key results from the exposure measurements sub-study.

#### **O04.01.14. Air Pollution and Infectious Disease Burdens on Lung Function in the Eastern Caribbean**

Steve Whittaker

*2. Yale School of Forestry and Environmental Science, New Haven, CT, United States.*

Abstract: Increasing respiratory illnesses have been observed in urban centers due to diminished air quality. This study evaluated associations between urban air pollutants in the Eastern Caribbean nation of St. Kitts-Nevis during drought and lung function among residents previously at risk for chikungunya infection. Mean concentrations of nitrogen dioxide (NO<sub>2</sub>) and particulate matter (PM<sub>10</sub>), collated between 2015 and 2017, were used to derive district-specific exposure categories (lower, moderate, higher). Cross-sectional health and lifestyle surveys were performed in conjunction with spirometry tests for 241 residents, ages 15 to 75 years, in 2016 and 2017. While NO<sub>2</sub> had no significant impacts, moderate and higher PM<sub>10</sub> exposures were associated with increased FEV<sub>1</sub>/FVC deficit (<70%), OR=2.2 (95% CI: 1.13, 4.34; p= 0.020) and 3.17 (95% CI: 1.00, 10.02; p=0.049), respectively. Adjusting for air quality and other factors, chikungunya infection among persons living in the same district for more than 3 years was linked reduced FEV<sub>1</sub>/FVC (OR=2.44 95% CI: 1.20, 4.93; p=0.013). Results further evidence that air pollution concentrations below guidelines set by the World Health Organization are associated with adverse respiratory health effects and suggest, for the first time, that a vector-borne disease, chikungunya, can be explicitly associated with reduced lung function.

#### **O04.01.15. Attitude Towards Livestock Farming Does Not Influence Associations between Farm Proximity and Respiratory Health in a Rural Population Study**

*1. IRAS, Utrecht University, Utrecht, Netherlands.*

*2. NIVEL, Utrecht, Netherlands.*

**Abstract:** Background: Several epidemiological studies have shown health effects of non-farming residents living in close proximity of livestock farms. Respondents' attitude towards farming may be a source of bias since concerns about environmental hazards may influence self-reported outcomes. The main aim was to assess whether earlier observed associations between proximity to farms and respiratory health effects were biased by participants' attitude towards farming. Methods: We developed an attitude score for the Dutch Livestock Farming and Neighbouring Residents' Health study population (n=2,457) by factor analysis of 13 questionnaire items related to attitudes towards livestock farming. Linear regression analysis was used to assess the association between attitude and potential determinants. The effect of attitude on associations between farm proximity and respiratory conditions was analysed by adding the attitude-score as a confounder in linear or logistic regression models. Interaction between farm exposure and the attitude-score was also tested. Results: In general, the study population had a positive attitude towards farming, in particular if participants were more familiar with farming. Older participants, females, ex-smokers, and individuals with a higher education had a more negative attitude. Both self-reported respiratory diseases and exposure to livestock farms were associated with a more negative attitude, which is a concern for our epidemiological study. Awareness bias might have played a role here, and attitude could potentially confound exposure-response relations. However, no indication was found that the associations between proximity to farms and respiratory health were confounded or modified by attitude. Conclusions: When studying self-reported data in environmental health studies, we recommend to measure attitude towards a potential hazard to study the impact of potential awareness bias.

#### **O04.01.16. Arsenic, One-Carbon Metabolism and Diabetes-Related Outcomes in the Strong Heart Family Study**

**Abstract:** Inorganic arsenic exposure and inter-individual differences in its metabolism have been associated with cardiometabolic risk. A more efficient arsenic metabolism profile (lower MMA%, higher DMA%) has been associated with reduced risk for numerous adverse health outcomes but an increased risk for diabetes-related outcomes. The mechanism behind these contrasting associations is equivocal; we hypothesized one carbon metabolism (OCM) may play a role. We evaluated the association between OCM-related variables (nutrient intake and genetic variants) and both arsenic metabolism biomarkers (iAs%, MMA% and DMA%) and diabetes-related outcomes (metabolic syndrome, diabetes, HOMA2-IR and waist circumference) in 935 participants free of prevalent diabetes and metabolic syndrome from the Strong Heart Family Study, a family-based prospective cohort comprised of American Indian tribal members aged 14+ years. OCM nutrients were not associated with arsenic metabolism, however, higher vitamin B6 was associated with diabetes-related outcomes (higher HOMA2-IR and increased risk for diabetes and metabolic syndrome). A polymorphism in an OCM-related gene, methionine synthase (MTR), was associated with both higher MMA% ( $\beta=2.57$ , 95% CI: 0.22, 4.92) and lower HOMA2-IR (GMR=0.79, 95% CI=0.66, 0.93 per 5 years of follow-up). Adjustment for OCM variables did not affect previously reported associations between arsenic metabolism and diabetes-related outcomes; however, the association between the MTR variant and all diabetes-related outcomes were attenuated or reversed direction after adjustment for arsenic metabolism. Our findings suggest MMA% may be a partial mediator in the association between OCM and diabetes-related outcomes. Formal mediation analyses are needed to confirm this finding. Additional research is needed to determine whether excess B vitamin intake is associated with increased risk for diabetes-related outcomes.

## **004.01.17. A Suspected Mesothelioma Cluster in Colombia: What We Know**

**Abstract:** Introduction: Asbestos are mineral fibers that have been used in a wide range of products. All forms of asbestos cause mesothelioma and cancers of the lung, larynx, and ovaries. The asbestos industry began operations in Colombia in 1942, with an asbestos cement facility located in the municipality of Sibate (current population 38,000). Historically the plant produced asbestos-cement roof tiles and water pipes. The latest figure available indicates that in 2012 the facility used 5,955 tons of asbestos. Inhabitants of Sibate have been complaining that a large number of people are being diagnosed and are dying from asbestos related diseases. Aim: The aim of this study is to investigate the potential existence of a mesothelioma cluster in Sibate. Methods: In 2015/16, 354 door-to-door health and socioeconomic surveys were applied in three large neighborhoods, to identify potential asbestos related cases. Asbestos exposure sources have also been studied, including soil-sampling campaigns conducted at locations that were determined using Geographic Information Systems. Results: Thirty-one (31) self-reported mesothelioma cases were identified with the surveys. For 21 of these cases, a copy of the medical diagnosis has been obtained (14 with immunohistochemistry report), as an initial step to confirm the original diagnosis. Core biopsy paraffins for each case are currently being collected for validation purposes. During the soil survey campaign, an underground layer of friable asbestos (chrysotile content 5-10%) was identified at different depths. This asbestos layer was created during the construction of landfills intended to desiccate areas of a water reservoir located next to the town. Conclusion: With the information collected so far, 3 of the 5 criteria established by the US CDC cluster investigation guidelines have been met. At this stage, the case in Sibate can be labeled as a suspected mesothelioma cluster, pending further confirmation of the mesothelioma diagnosis.

**004.01.18. Describing Roles for a Range of Natural Environments in Adverse Mental Health Outcomes and Neighborhood Social Cohesion across Metro Vancouver, Canada**

Emily Rugel

*Emily J. Rugel<sup>1</sup>, Michael Brauer<sup>1</sup>, Richard Carpiano<sup>2</sup>, Sarah B. Henderson<sup>3</sup>*

*2. Department of Sociology, University of California, Riverside, Riverside, CA, United States.*

*3. British Columbia Centre for Disease Control, Vancouver, BC, Canada.*

**Abstract:** In a rapidly urbanizing world, identifying evidence-based strategies to design healthy cities is essential. Although urban living offers increased access to critical resources and can help to mitigate climate change, dense environments are often higher in physical and psychological stressors and lower in social cohesion, which is known to support health. One component of urban form that can ameliorate these stressors is nature: greenspace such as parks and street trees and bluespace such as rivers and oceans. In this project, we applied a Natural Space Index (NSI) previously developed for greater Vancouver, Canada to explore the relationship between the presence, access, and form of natural space and: (1) major depressive disorder; (2) negative mental health; and (3) psychological distress. In addition, we examined associations between the NSI and perceived social cohesion (measured via self-reported sense of community belonging [SoC]), as well as potential mediation of the relationship between nature and mental health via increased SoC. Using data from the nationally representative cross-sectional 2012 Canadian Community Health Survey-Mental Health (sample weighted  $n=1,930,048$ ), we found no associations between any NSI measures and mental health in models adjusted for 11 demographic, socioeconomic, household arrangement, health, and urban design confounders. However, two measures of publicly accessible neighborhood (500m) nature were associated with increased odds of higher SoC: percentage of public greenspace [AOR=1.05/95%CI=1.00, 1.10 for very strong vs. very weak SoC] and percentage of public natural space [AOR=1.05/95%CI=1.01,1.10 for very strong vs. very weak; AOR=1.04/95%CI=1.01,1.08 for somewhat strong vs. very weak]. In addition, higher levels of SoC were associated with improvements in all three mental health outcomes. These findings suggest an indirect effect of publicly accessible nature on improved mental health via increased social cohesion.

O04.01D. Health Outcomes and Biomarkers Associated with Household Cooking and Biomass Burning 2
